SMALL-SCALE RELEASE OF NON-GENE DRIVE MOSQUITOES IN BURKINA FASO: FROM ENGAGEMENT IMPLEMENTATION TO ASSESSMENT, A LEARNING JOURNEY

Lea Pare Toe[1], **Nourou Barry**[1], Anselme D. Ky[1], Souleymane Kekele[1], Wilfrid Medah[1], Korotimi Bayala[1], Mouhamed Drabo[2], Delphine Thizy[2], Abdoulaye Diabate[1]

[1]Institut de recherche en sciences de la santé (IRSS/UNB), Bobo Dioulasso, Burkina Faso, [2]Department of Life Sciences, Imperial College London, London, UK, Bobo Dioulasso, Burkina Faso

Innovative tools are needed to complement the existing approach for malaria elimination. Gene drive mosquitoes are one potential new technology in the control of malaria vectors. Target Malaria is one of the research projects developing this technology, and in July 2019, the project proceeded to an important step for this evaluation pathway: the small-scale release of non-gene drive sterile male mosquitoes in a village in Burkina Faso. In addition to the entomological and laboratory work to prepare for this important milestone, significant community and stakeholder engagement work was done. This study provides a review of engagement activities relevant to field trials on non-gene drive genetically-modified mosquitoes as well as an assessment framework—using both qualitative and quantitative studies as well as an audit procedure. The latter was implemented to evaluate whether the release activities could proceed with the appropriate level of agreement from the community. This paper shows the importance of this first phase of work to innovate and learn about engagement processes for responsible research in the field of genetic approaches for malaria vector control. The function of these assessments is crucial for the learning agenda. The assessments demonstrated ways to increase understanding and ensure effective progress with field studies and, therefore, the pathway for responsible research. In conclusion, gene driven technology is increasingly considered as a promising approach to control vector borne diseases, in particular malaria. Stakeholders' involvement in this research process is one of the recurring requirements in international guidance documents. With this paper Target Malaria offers an opportunity to explore the practical achievements and challenges of stakeholder engagement during early phases of a technology evaluation, and in particular how it implemented an assessment framework to learn from its experience.

ACCELERATING MALARIA ELIMINATION IN CAMBODIA: ANALYSIS OF IMPACT OF THE"LAST MILE" INTENSIFICATION PLAN

Siv Sovannaroth[1], Chawarat Rotejanaprasert[2], Pengby Ngor[2], Anchalee Jatapai[2], Richard J. Maude[2]

[1]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [2]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand

The Greater Mekong Subregion countries are preparing to enter the final phase of malaria elimination. To maintain this momentum, more nuanced, and targeted approaches are required. Cambodia's National Center for Parasitology, Entomology, and Malaria Control (CNM) and partners are implementing an intensification plan called the "last mile" strategy to accelerate progress. This comprises a focalized aggressive set of interventions including house-to-house fever screening (AFS), targeted bed and hammock net distribution, chemoprophylaxis of forest goers (IPTf) and target drug administrative (TDA). Implementation is supported by village and mobile malaria workers and health centres with outreach to remote communities. Analysis of routine malaria data was done to measure the impact of the last mile strategy and guide future plans. From 25th December 2020 to 1st March 2023, last mile had been implemented in 123 villages (population 75,195). Village mean and median malaria annual parasite index (API) during the 12 months prior to implementation were 1.075 and 0.258 (IQR: 0, 0.036), respectively. In the 12 months after the intervention, these were 0.178 and 0 (IQR: 0, 0). The paired difference of the village median APIs was compared using the Wilcoxon signed-rank test giving a p-value of < 0.0001. To compare the declining rates, an interrupted time series analysis was performed using segmented regression. Before the last mile implementation, mean and median declining incidence rate ratio were -0.106 and -0.114 (IQR: -0.152, -0.061), respectively, compared to -0.503 and -0.547 (IQR: -0.576, -0.511) after the intervention, $p < 0.0001$. Overall cases in these villages decreased by 52% from 1806 in 2020 to 863 in 2022, despite the number of malaria tests performed remaining steady. The reduction in cases was even higher among mobile populations at 59%. Although this initial result suggests the last mile intervention significantly reduced malaria cases in implementation villages, implementation is ongoing and the final analysis will be presented. Lessons learned and implications for other countries aiming for elimination will be discussed.

MALARIA TREND AND IDENTIFICATION OF RISK GROUPS IN AN ELIMINATION SETTING, 2019-2022

Safia Mohammed[1], Majda Hassan[1], Bimkubwa Khamis[1], Bakar Mohammed[1], Shija J. Shija[1], Mohamed Haji[1], Humphrey Mkali[2], Saidi Mgata[2], Stella Makwaruzi[2], Michael Gulaka[2], Nicodemus Govella[2], Sigsibert Mkude[2], Erik Reaves[3], Naomi Serbantez[4], Chonge Kitojo[4], Geofrey Makenga[2], Isobel Routledge[5], Roly Gosling[5]

[1]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [2]Dhibiti Malaria project, Population Services International, Dar es Salaam, Tanzania, United Republic of, [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [5]PMI Insights Project, Malaria Elimination Initiative, University of California San Francisco, California, CA, United States

Zanzibar has achieved significant progress in reducing malaria transmission over the past fifteen years; however, elimination has not yet been achieved. In elimination settings, malaria infections tend to occur in older age groups and cluster in certain households and subpopulations. The latter clustering is often related to certain risk factors, such as occupation or mobility, which place these individuals at higher risk of malaria infection relative to others. We extracted malaria surveillance data from 2019-2022 available in the Coconut system (Zanzibar malaria surveillance system) to assess malaria case trends over time and identify risk factors across sub-populations using logistic regression to inform development of a Reactive Drug Administration (RDA) strategy in Zanzibar. Malaria cases recorded in the Coconut system were identified passively through microscopy or malaria Rapid Diagnostic Test (mRDT) at the health facility or through the subsequent mRDT testing at household level as part of routine Reactive Case Detection. There was a notable decrease (62.2%) in malaria cases from 11,613 cases in 2019 to 4,389 cases in 2022. Overall, 60% of cases were classified as imported throughout the years. Districts with a high proportion of local cases were Micheweni (45%), Mjini (33%), Wete (30%), and Magharibi B (30%). In all years, a high risk of malaria was seen in males compared to female [OR=1.6; 95% CI 1.5-1.7] and in individuals aged 15-45 years compared to those below 15 years [OR=2.1; 95% CI 1.9-2.1]. Since the 15-45 years age group is the working class in most communities, the findings suggest there may be behavioral or occupational exposure such as being fishermen, night watchmen, and students that are associated with malaria transmission outside of the household. A further investigation to better characterize the high-risk populations, including occupational risks and social behaviors, is recommended to guide the deployment of appropriate interventions, such as RDA and targeted vector control in this elimination setting.

EFFECTIVENESS OF THE EXPANDED ROLE OF COMMUNITY HEALTH WORKERS IN MALARIA ELIMINATION IN MYANMAR: AN OPEN STEPPED-WEDGE CLUSTER-RANDOMISED CONTROLLED TRIAL

Win Han Oo[1], Win Htike[1], May Chan Oo[1], Ei Phyu Htwe[1], Aung Khine Zaw[1], Kaung Myat Thu[1], Naw Hkawng Galau[1], Julia C. Cutts[2], Nilar Aye Tun[1], Nick Scott[2], Katherine O'Flaherty[2], Paul A. Agius[3], Freya J I Fowkes[2]

[1]Burnet Institute, Yangon, Myanmar, [2]Burnet Institute, Melbourne, Australia, [3]Deakin University, Melbourne, Australia

The network of malaria volunteers in the Greater Mekong Subregion have significantly contributed to progress towards the goal of malaria elimination by 2030. As Mekong countries approach malaria elimination, the motivation and social role of malaria volunteers, and malaria testing rates, have declined in parallel with decreasing malaria burden. To address this issue, the Community-delivered Integrated Malaria Elimination (CIME) model was developed from an evidence-base and field-tested in Myanmar to evaluate its effectiveness and cost-effectiveness. An open stepped-wedge cluster-randomised controlled trial randomised at the village level was conducted in 72 villages in Yangon Region from 1 November 2021 to 17 April 2022 (24 weeks) to evaluate the CIME model that integrates services for malaria, dengue, tuberculosis, childhood diarrhoea and non-malaria fever compared to the existing malaria volunteer model. One-off and continuous implementation costs of the Models were calculated. Compared to the existing integrated malaria volunteer model, a 23% relative increase in village rapid diagnostic testing for malaria after the introduction of the CIME model was observed in both *intention-to-treat* (adjusted incidence rate ratio = 1.23, 95%CI = 1.01, 1.50, p= 0.036) and *as-treated* analyses (adjusted incidence rate ratio = 1.23, 95%CI = 1.01, 1.49, p=0.042), adjusting for time and season. Among the 2,540 visits suspected of dengue, tuberculosis, childhood diarrhoea and febrile illness, the CIME volunteers provided initial treatment and referral services to 12% (307/2,540) of them. The total cost per volunteer per one-, three- and five-year period was USD 2,992 USD 8,893 and USD 14,794 respectively for the CIME model, and USD 1,168 USD 3,492 and USD 5,816 respectively for the existing malaria volunteer model. Although the CIME model is associated with additional costs for providing health services for common tropical diseases, it is effective in increasing the annual blood examination rate required for malaria elimination accreditation compared to the existing malaria volunteer model.

MALARIA CASE-BASED SURVEILLANCE FOR THE INTERRUPTION OF LOCAL MALARIA TRANSMISSION IN TANZANIA MAINLAND

Elizabeth Kasagama[1], Khalifa Munisi[2], Denis Kailembo[1], Fabrizio Molteni[1], Noela Kisoka[1], Pai Chambongo[2], Christian Lengeler[3], Samwel Lazaro[2], Sijenunu Aron[2]

[1]SWISS TPH, Dar es Salaam, Tanzania, United Republic of, [2]NMCP, Dodoma, Tanzania, United Republic of, [3]SWISS TPH, Swiss Tropical and Public Health Institute, Basel, Switzerland

Tanzania mainland is implementing the 2021- 2025 National Malaria Strategic plan. This is hand in hand with the stratification of sub-national levels in malaria risk strata and the introduction of tailored intervention according to epidemiolocal risk strata as suggested by the Global Technical Strategy (GTS) for malaria 2016-2030. Malaria Case-Based Surveillance (mCBS) is among interventions in councils with very low malaria transmission risk and aims to interrupt malaria transmission contributing to the local elimination of malaria in active foci. The implementation is organized according to Health facilities' malaria disease burden defined as confirmed malaria cases diagnosed per month per health facility. Malaria Case Based Surveillance is implemented in Arusha, Iringa, Kilimanjaro, Manyara, and Njombe regions. There are six steps in conducting mCBS triggered by the passive detection of a malaria case at a health facility. This involves passive case detection, case classification, and notification, case follow-up and reactive case detection, proactive case detection, focus identification and classification, focus investigation, and focus response. All steps are done by trained healthcare workers and Region/Council Health Management Teams using the mCBS protocol under the guidance of the National Malaria Control Programme. A total of 5,250 passive cases were detected at both the private and public health facilities in Arusha 2,806 cases, Kilimanjaro 1,173 cases, Njombe 309 cases, and Manyara 962 cases. Among these detected passive cases 2,149 were classified as local cases (diagnosed within the same council where transmission occurred) and 3,101 were classified as imported cases (diagnosed in a council where transmission did not occur). Most of the local cases were from peasants, children, pastoralists, and infants. All local passive cases were followed up, 1647 were tested and only 65 cases (3.9%) tested positive and were treated. Malaria Case Based Surveillance is pivotal in the detection of asymptomatic cases that are missed at health facilities and provides a better understanding of risk factors in transmission foci.

ENHANCED ACTIVE CASE DETECTION TO ELIMINATE MALARIA IN YALA PROVINCE, THAILAND

Suravadee Kitchakarn[1], Sathapana Naowarat[2], Prayuth Sudathip[1], Pratin Dharmarak[3], Deyer Gopinath[4], Hope Simpson[5], Rungrawee Tipmontree[1], Chantana Padungtod[1], Donal Bisanzio[2], Niparueradee Pinyajeerapat[6], David Sintasath[6], Jui A. Shah[2]

[1]Division of Vector Borne Diseases, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, [2]Inform Asia: USAID's Health Research Program, RTI International, Bangkok, Thailand, [3]Independent consultant, Bangkok, Thailand, [4]World Health Organization, Nonthaburi, Thailand, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Regional Development Mission for Asia, Bangkok, Thailand

Thailand's malaria elimination strategy includes several active case detection (ACD) methods, both proactive and reactive. In Yala Province, where there is intermittent civil unrest, malaria cases declined from 1,592 in fiscal year 2015 (FY15) to 57 in FY22. In FY16, following a successful pilot project among military personnel, local authorities expanded ACD to include civilian populations, relying on community health workers to navigate the unique context. This study used routine surveillance data to examine ACD yield (i.e., confirmed cases among total screened) and trends among all 821,334 blood draws and 14,855 confirmed cases in Yala from FY15-FY22. T-tests were run for mean differences, and spatial trends were assessed using intercept-only generalized linear regression models. Over the study period, ACD screenings represented 58.3% of all blood draws in Yala (compared to 74.1% nationally). Among 478,708 ACD blood draws, 1,328 cases were detected, representing a yield of 0.28% (range 0.01%-0.92%, compared to 0.07% nationally). In FY18, local authorities replaced other proactive methods with special case detection (SCD), which used a small team to screen every village member, in an effort to reduce costs and optimize ACD. As a result, SCD screenings increased from 1,769 in FY17 to 15,546 in FY18; however, SCD yield significantly decreased from 0.73% in FY17 to 0.10% in FY18 and down to 0.01% by FY22 ($p < 0.05$). Yield for reactive case detection was higher in the first 6 years compared to the last two years (0.39% compared to 0.004%, $p < 0.05$), consistent with declining malaria incidence. Geospatial results showed that subdistricts with higher ACD yield clustered in the center of the province. Although ACD yield in Yala is higher than elsewhere in Thailand, these results show that there is an opportunity to further refine targeting and methods to make efficient use of resources. Epidemiological data could help quantitatively define high-risk populations and areas. Thailand plans to use these results and further analyses to develop standard operating procedures to accelerate malaria elimination among these at-risk populations in Yala.

A PROGRAM EVALUATION OF REACTIVE FOCAL DRUG ADMINISTRATION IN NORTHERN SENEGAL

Ellen Ferriss[1], Caterina Guinovart[2], Yakou Dieye[3], Moustapha Cisse[3], Abiboulaye Sall[3], Tidiane Thiam[3], Adam Bennett[1]

[1]PATH, Seattle, WA, United States, [2]PATH, Barcelona Institute for Global Health, Barcelona, Spain, [3]PATH, Dakar, Senegal

In 2016, Senegal's Programme National de Lutte contre le Paludisme began conducting reactive focal drug administration (rFDA), the presumptive treatment of index case compound members, in 10 low transmission districts. This controlled interrupted time-series analysis used routine surveillance data from 2015 to 2020 to estimate the impact of rFDA on passively detected malaria case incidence in 157 health facility catchment areas (HFCAs) receiving rFDA with > 60% coverage. Ninety-four HFCAs receiving the standard intervention package were used as a comparator, and 2015 through 2016 taken as baseline. Negative binomial regression models were stratified by transmission intensity and time period and adjusted for rainfall, vegetation index, temperature, month, urbanicity, outpatient visits, community health worker density, and bednet and indoor residual spraying coverage. Among facilities with baseline annualized incidence rates of < 10 cases per 1,000 population and high intervention coverage through 2020, incidence rates were similar across groups (IRR = 0.97, 95% BCI = 0.67, 1.42), as were monthly declines in incidence rates (IRR = 1.00, 95% BCI = 0.98, 1.42) following rFDA roll-out, possibly reflecting the prevailing impact of universal bednet distributions in 2016 and 2019. In contrast, from roll-out through September 2018, incidence rates were estimated to be 36% lower in areas receiving rFDA (IRR = 0.64, 95% BCI = 0.45, 0.91), with a 3% greater decline in slope each month in rFDA areas than in control areas compared to baseline (IRR = 0.97, 95% BCI = 0.94, 1.00). Among facilities with baseline incidence rates of ≥ 10 cases per 1,000 population, incidence rates were not statistically significantly different between rFDA and comparison groups (IRR = 0.77, 95% BCI = 0.48, 1.24) from roll-out through September 2018, when intervention coverage remained high, nor were monthly declines in incidence rates (IRR = 0.97, 95% BCI = 0.93, 1.01). RFDA was not associated with sustained, lower incidence rates compared to the standard intervention package; however, the use of incomplete routine surveillance data may have influenced these findings.

5007

PREGNANT WOMEN EXCLUSION IN CLINICAL TRIALS FOR MALARIA, TUBERCULOSIS, AND COVID-19: A REVIEW OF TRIAL REGISTRY DATA

Elias Rejoice Maynard Phiri[1], Claudia Emerson[2], Lizzie Divala[3], Aaron Roberts[2], Lufina Tsirizani-Galileya[4], Randy George Mungwira[5], Titus Divala[6]

[1]Malawi-Liverpool-Wellcome Programme, Blantyre, Malawi, [2]MacMaster University, Hamilton, ON, Canada, [3]Glasgow University, Glasgow, United Kingdom, [4]University of Cape Town, Cape Town, South Africa, [5]World Health Organization, Turin, Italy, [6]Wellcome Trust, London, United Kingdom

Clinical trials are critical in establishing the safety, efficacy, dosing, and target population of new interventions, yet they often exclude pregnant women. The extent of exclusion of pregnant women in clinical trials is not well-described. This systematic review aimed to describe the extent of exclusion of pregnant women in clinical trials for malaria, tuberculosis, and COVID-19 vaccine. We searched clinicaltrials.gov for trials targeting adult females for malaria, tuberculosis, and COVID-19 vaccine between the years 2000 and 2021. We conducted separate searches for each condition and performed descriptive analysis to report the proportion of studies that included pregnant women. We also examined and reported the clinical development pathway (trial phases). As of December 18, 2021, clinicaltrials.gov listed 399,532 studies, of which 1,173 met our search criteria. Of these, 1,116 studies verified pregnancy criteria and were eligible. 95% (1,064) of the eligible studies excluded pregnant women. Of the 52 (5%) that included pregnant women, 90% (47) were specifically pregnancy trials. Among them, 65% (34) were Phase III, 10% Phase II/III, 10% Phase II, 12% Phase I, and 4% Phase I/II. A total of 45 malaria, 5 TB, and 2 COVID-19 vaccine trials included pregnant women. Our findings confirmed a high exclusion of pregnant women from the clinical product development pathway. This is attributed to the protectionist ethic. However, we argue for an urgent paradigm shift to more inclusion as exclusion prevents the collection of data that informs assessments of safety, efficacy, and therapeutic dosage, thereby precluding adequate information for informed decision-making in pregnancy. It is crucial to tip the clinical development pathway in favor of pregnant women to ensure their safety and provide better therapeutic options.

5008

NODDING SYNDROME CLINICAL CHARACTERISTICS, RISKS FACTORS, ACCESS TO TREATMENT, AND PERCEPTIONS IN GREATER MUNDRI AREA, SOUTH SUDAN

Gasim Abd-Elfarag[1], Jake Mathewson[2], Lukudu Emmanuel[1], Arthur Edridge[3], Stella van Beers[2], Mohamed Sebit[4], Robert Colebunders[5], Michaël van Hensbroek[3], Ente Rood[2]

[1]Access for Humanity, Juba, South Sudan, [2]Kit-Royal Tropical Institute, Amsterdam, Netherlands, [3]Amsterdam Center for Global Health, Department of Pediatrics and Department of Global Health, Amsterdam, Netherlands, [4]University of Juba, Juba, South Sudan, [5]Global Health Institute, University of Antwerp, Antwerp, Belgium

Nodding syndrome (NS) is a neurodegenerative disease of unknown etiology, affecting poor people in Tanzania, South Sudan, Uganda, the Democratic Republic of Congo, Cameroon, and the Central African Republic. It presents with head nodding and other seizures; often associated with debilitating complications, including impaired cognitive and physical development and delayed sexual maturity. Previous attempts to identify a potential cause have focused on infections, nutrition, toxins, autoimmunity, hormonal and metabolic derangements, and genetic factors, but all were inconclusive. Control of onchocerciasis and its vector, the blackfly, by community-directed treatment with ivermectin and larviciding of rivers were proposed to prevent new cases. However, certain communities in the affected areas believe that NS is transmitted from person-to-person and thus can be prevented by isolation of cases from other family members or peers. To further unravel the many unknowns of NS, we conducted a house-to-house survey and case-control studies in Mundri County, South Sudan to investigate the clinical characteristics, risk factors, access to treatment and perceptions about NS. In total, 224 cases with median age of seizure onset 10 years were identified. Head nodding only was reported in 22.3%, and head nodding plus other types of seizures in 77.7% cases. Wasting, stunted growth, delayed sexual development and speech and behavioural abnormalities were observed in 23.6%, 22.2%, 17.3%, 19.4% and 5.6% cases, respectively. The consumption of rat-meat, but not other bushmeat was associated with an increased risk of NS (OR 9.31, 95% CI 1.27–406.51). Cases were more likely to have taken ivermectin in the last 5 years (OR 2.40, 95% CI 1.33–4.43), and were less likely to share a bedroom with other children (OR 0.06, 95% CI 0.02–0.16) or adults (OR 0.27, 95% CI 0.13 0.56). In conclusion, rat-meat consumption is an unlikely risk factor for NS, and ivermectin intake was more common among NS cases than controls. Importantly, we documented that children with NS are stigmatized because of the misconception that NS is transmitted through direct contact.

5009

DIABETES-ASSOCIATED MAJOR LIMB AMPUTATION IN SOLOMON ISLANDS: EPIDEMIOLOGICAL CHARACTERISTICS AND CLINICAL MANAGEMENT

Dylan Bush[1], Thomas Fitzpatrick[2], Adrian Garcia Hernandez[3], Rooney Jagilly[4], Eileen Natuzzi[5], Mickey Olangi[6], Mark Love[7], Jones Ghabu[4], Hugo Bugoro[8], Alexandra Martiniuk[9]

[1]Solomon Islands Ministry of Health and Medical Services, Honiara, Solomon Islands, [2]Australian Volunteers International, Melbourne, Australia,

[3]Columbia University, New York City, NY, United States, [4]Solomon Islands National Referral Hospital, Honiara, Solomon Islands, [5]Georgetown Center for Australian, New Zealand & Pacific Studies, Georgetown, DC, United States, [6]Kilu'ufi Hospital, Auki, Solomon Islands, [7]Griffith University, Brisbane, Australia, [8]Solomon Islands National University, Honiara, Solomon Islands, [9]University of Sydney School of Public Health, Sydney, Australia

Solomon Islands is classified as a UN "Least Developed Country" and faces the 9th highest prevalence of diabetes globally. Limited resources, poor infrastructure, and challenging geography make medical and surgical delivery difficult. This retrospective study aims to describe the characteristics and clinical management of patients undergoing diabetes-associated major limb amputation. It is the first study on major limb amputation in Solomon Islands. Demographic and clinical data was abstracted from charts belonging to patients with diabetic ulcers who underwent major limb amputation at four surgical centers. Summary statistics were gathered from this dataset. Over a 5-year period (2018-2023), 338 adults underwent major limb amputation secondary to diabetes-associated infections. Of these, 285 patients had medical records available for data abstraction. The median age for these patients was 55 years (range: 18-83), 50.5% (N=144) were male. The most common known cause of initial ulceration was general trauma (N=93). The second most common cause was rat bites (N=15). The mean Wagner's classification score was 3.59. 97.5% (N=278) of patients experienced delay in accessing amputation. Late presentation was also common with 33% (N=93) waited 30 or days before seeking medical attention. Blood sugar levels were controlled in only 1.4% (N=4) of patients during hospital stay. The mean wait time between recommendation of amputation and operation was 7 days (range: 0-86). Among all patients who underwent major limb amputation, 12% (N=41) died prior to discharge. In conclusion, major limb amputation is a costly and radical procedure which contributes to severe disability in the local context. Earlier presentation, effective diagnosis of foot/limb infection, aggressive management of infection, and earlier access to surgical care are likely to prevent limb loss. This research shows the importance of investing in diabetes prevention to prevent downstream complications. Future research should investigate locally modified and sustainable methods to improve limb salvage and preventative foot care.

LEVERAGING PARTICIPATORY MAPPING AND FINE-SCALE GEOSPATIAL ANALYSES TO OPTIMIZE COMMUNITY-BASED HEALTHCARE PROGRAMS AND POLICIES

Felana A. Ihantamalala[1], Vincent Herbreteau[2], Christophe Revillion[3], Lucas Longour[2], Michelle V. Evans[2], Mauricianot Randriamihaja[1], Laura F. Cordier[1], Benedicte Razafinjato[1], Luc Rakotonirina[1], Isaïe Jules Andriamiandra[4], Karen E. Finnegan[5], Matthew H. Bonds[5], **Andres Garchitorena**[2]

[1]ONG Pivot, Ranomafana, Madagascar, [2]Institut de Recherche pour le Developpement, Montpellier, France, [3]Université de La Réunion, La Réunion, France, [4]Ministry of Public Health, Antananarivo, Madagascar, [5]Harvard Medical School, Boston, MA, United States

In rural communities, where geography is often the main barrier to access primary healthcare, community health workers (CHWs) provide essential primary health services. Sophisticated geospatial data and analyses are transforming health systems; however, these approaches are rarely developed to serve community health programs and policies. As an integral part of the public health system, there is a critical need to develop evidence-based decision making tools (e.g data dashboards, hotspot mapping, and precision health) at local scales relevant for community health programs. A set of high-resolution geospatial data, analyses and decision-making tools are being integrated into community health programs in Ifanadiana, a rural district of Madagascar. The backbone of this initiative was the collection of high-quality geospatial data for the district via participatory mapping in OpenStreetMap, resulting in the mapping of over 100,000 buildings and 20,000 km of footpaths. This data enabled us to accurately estimate field-derived travel times to primary care facilities for each household in the district and identify geographic distance as a major barrier to primary care use. We then demonstrated that geographic barriers persist at the community health level and we developed a spatial algorithm to optimize the location of community health sites within each CHW catchment, the results of which are embedded in an online data dashboard. Finally, we are using this dataset to optimize the planning and implementation of proactive CHW programs, estimating optimal routes for CHWs to visit every household in a catchment, contributing towards universal access to healthcare. All of these geospatial analyses are publicly available as e-health tools to guide programs. Our work highlights how high-resolution geospatial analyses can be integrated into existing community health programs to address spatial inequalities and barriers to achieving universal health coverage. Scale-up of these tools could contribute to optimizing community health systems globally, in line with the 2018 guidelines from the World Health Organization.

WHO IS MISSED IN A COMMUNITY-BASED SURVEY: DIFFERENCES IN SOCIO-DEMOGRAPHIC ERISTICS AND HEALTHCARE SEEKING AMONG MISSED AND SAMPLED INDIVIDUALS FOR A SEROSURVEY IN ZAMBIA AND IMPLICATIONS FOR BIASED ESTIMATES OF HEALTHCARE SEEKING, VACCINATION COVERAGE, AND SEROPREVALENCE

Natalya Kostandova[1], Simon Mutembo[1], Christine Prosperi[1], Francis D. Mwansa[2], Chola N. Daka[3], Harriet Namukoko[3], Bertha Nachinga[3], Gershom Chongwe[4], Innocent Chilumba[4], Kalumbu H. Matakala[5], Gloria Musukwa[5], Mutinta Hamahuwa[5], Webster Mufwambi[4], Japhet Matoba[5], Kenny Situtu[4], Irene Mutale[4], Edgar Simulundu[5], Phillimon Ndubani[5], Alvira Z. Hasan[1], Shaun A. Truelove[1], Amy K. Winter[6], Andrea C. Carcelen[1], Amy Wesolowski[1], Bryan Lau[1], William J. Moss[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Directorate of Public Health and Research, Ministry of Health, Lusaka, Zambia, [3]Zambia Statistics Agency, Lusaka, Zambia, [4]Tropical Diseases Research Centre, Ndola, Zambia, [5]Macha Research Trust, Macha, Zambia, [6]University of Georgia, Athens, GA, United States

As serological assessments play an increasing role in measuring disease burden, identifying population immunity gaps, and guiding vaccination strategies globally, understanding the impact of sampling biases on outcomes of interest is increasingly important. In Zambia, a serological survey was conducted in two districts using residual samples from health facilities and validated by comparison with a concurrent community-based serosurvey. We conducted a follow-up study to assess differences in characteristics of households and individuals excluded from the sampling frame of the community-based serosurvey (23% of households) compared to those included and evaluated the magnitude of the bias in healthcare seeking, vaccination coverage, and measles seroprevalence. The initially missed households were smaller, less likely to have children, and were 15% to 29% more likely to be headed by women. Missed individuals came from less wealthy households, with imbalances in adults for sex and occupation, and were more likely to seek care at health facilities. Nevertheless, simulating a survey in which missed households were included in the sampling frame did not result in significant differences in the outcomes of interest, i.e., coverage of a second dose of measles vaccine, healthcare seeking, and measles seroprevalence, with less than a 5% difference in these outcomes. Two of the clusters had evidence of geographical clustering of missed households. Simulations of enumeration strategies in which additional households were enumerated until a specified threshold was reached resulted in a reduction in the estimated bias. These findings underscore that, even as community-based studies are upheld as the gold standard study design in assessing immunity gaps and underlying community health characteristics, results from these studies should be interpreted in the context of the study methodology and challenges during implementation, which include likely gaps in establishing accurate and up-to-date sampling frames. Failure to account for these gaps may result in biased estimates and detrimental effects on decision-making.

5012

THE EFFECT OF COMMUNITY-BASED PACKAGE OF INTERVENTIONS ON IMPROVING INSTITUTIONAL DELIVERY CARE SERVICES UTILIZATION IN ARBA MINCH HDSS, SOUTHERN ETHIOPIA: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Mekdes Kondale Gurara[1], Veerle Draulans[2], Jean-Pierre Van geertruyden[3], Yves Jacquemyn[4]

[1]Arba Minch University, Arba Minch, Ethiopia, [2]KU Leuven, Leuven, Belgium, [3]Antwerp University, Belgium, Belgium, [4]Antwerp University, Antwerp, Belgium

Regular utilization of maternal healthcare services reduces maternal morbidity and mortality. However, evidence shows that women do not use the existing services, especially institutional deliveries, with a substantial inequity between urban and rural areas. This study evaluated the effect of a package of community-based interventions on the improved institutional birth rate in rural Ethiopia. We conducted this cluster-randomized controlled trial (NCT05385380) from 2019 to 2021 at the Arba Minch Health and Demographic Surveillance System site. We randomly assigned six kebele clusters to the intervention and four to the control arm. We used a package of interventions, which included providing information on safe motherhood via videos or audiocassettes with a birth preparedness card for pregnant females, training for community volunteers and health extension workers, and improving maternity waiting home services. Women in the control arm received routine services only. We used generalized mixed-effects logistic regression models to evaluate the effect of the intervention on the outcome variables. We enrolled 727 pregnant females across the 10 clusters, with a 617 (84.9%) successful follow-up rate. The proportion of institutional deliveries in the intervention arm was increased by 16.1% from 36.4% (174/478) at the baseline to 52.5% (224/427) at the end line (Adjusted odds ratio [AOR] for McNemar's Test = 1.5; 95% confidence interval [CI]: 1.1 to 2; $p < 0.001$). However, the control arm had a 10.3% decrease in institutional deliveries (from 164/249 to 105/190). In addition, pregnant females who received the intervention were 2.8 times (AOR 2.8; 95% CI: 1.2, 6.4) likelier to give birth at a health institution than those in the control arm. This study demonstrates that an integrated community-based intervention package can increase utilization of institutional delivery care services in rural Ethiopia. Therefore, we recommend that functioning maternity waiting homes and audio-video-supported education for pregnant women be part of routine maternal healthcare to achieve the "leave no one behind commitment" in maternal health.

5013

IMPACT OF A MOBILE OBSTETRIC REFERRAL EMERGENCY SYSTEM (MORES) ON REDUCING CARE DELAYS IN RURAL LIBERIA

Christopher Reynolds[1], Nancy Lockhart[1], Joseph Sieka[2], Clare Edson[1], Aloysius Nyanplu[3], Jody Lori[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]University of Liberia, Monrovia, Liberia, [3]Bong County Health Team, Gbanga, Liberia

Maternal mortality disproportionately affects low- and middle-income countries, including Liberia. Due especially to late presentation with infectious conditions, maternal mortality can be reduced with obstetric triage systems which are unavailable in Liberia. Mobile health interventions are a promising but underutilized method to reduce care delays for such patients. This study assessed the impact of a Mobile Obstetric Referral Emergency System (MORES) in rural Liberia. Front-line health providers working at 18 rural health facilities and 2 hospitals received training on obstetric triage and MORES. Data on 300 patients at three time points: 0, 6-months, and 12-months were collected to assess care delays and clinical outcomes. MORES usability data were recorded through WhatsApp messages and provider interviews. Baseline and midline results (N=200) are reported with endline data being collected. Results demonstrated a significant decrease in time from decision to incision for Cesarean section (n=60) from 482 minutes pre-training to 186 minutes post-training (M=296 min, 4.93 hours reduced). In total, 43 providers referred 359 patients with thousands of messages through MORES. Messages included infectious diagnoses, transfer rationale, time from rural facility to hospital, and patient outcomes. MORES was highly usable and acceptable and demonstrated components of health systems strengthening, including decreased transfer times, improved inter-professional dynamics, feedback mechanisms, exposing hidden delays, and establishing a preliminary electronic health record with follow-up for high-risk patients. MORES demonstrated high acceptability and improved clinical metrics, particularly reduced delay to C-section. Capacity building included patient tracking in a setting where electronic health records are unavailable, and where formal follow-up care is not standardized. Future studies should evaluate scalability throughout Liberia and mixed methods analysis of patient perceptions.

5014

DETECTING CIRCULATING MALARIA-INFECTED ERYTHROCYTES IN HUMANS WITHOUT A DROP OF BLOOD

Jillian N. Armstrong[1], Aayire C. Yadem[2], Mustafa Sarimollaoglu[3], Kiki Massa Civian[4], Jean Michel Ndifo Ngamba[5], Yulian A. Menyaev[3], Anastasie Mbe[5], Kacey Richards[1], Martina Wade[1], Yushun Zeng[6], Ruimin Chen[6], Qifa Zhou[6], Elvis Meten[5], Rodrigue Ntone[4], Yves Le Grand Napa Tchuedji[5], Safi Ullah[3], Ekaterina I. [1]Yale School of Public Health, New Haven, CT, United States, [2]University of Arkansas at Little Rock, Little Rock, AR, United States, [3]University of Arkansas for Medical Sciences, Little Rock, AR, United States, [4]Epicentre, Yaoundé, Cameroon, [5]University of Yaoundé I, Yaoundé, Cameroon, [6]University of Southern California, Los Angeles, CA, United States

Highly-sensitive, novel point-of-care (POC) malaria diagnostics are necessary to address the limitations of current POC methods. We developed and tested a breakthrough, noninvasive photoacoustic (PA) flow cytometry (PAFC) device to detect hemozoin, a universal biomarker of blood-stage *Plasmodium* infection. Here, we present results of the first-in-human application of a novel PAFC device, the Cytophone, which uses high-pulse-rate lasers and an innovative ultrasound 16-transducer array to noninvasively detect circulating malaria-infected red blood cells (iRBCs) *in vivo*. Our technological design allows for the identification of iRBCs through the specific PA signal shapes, widths, and time delays of these cells compared to signals from uninfected blood, skin, and motion artifacts. We conducted a pilot diagnostic performance study in n=27 Cameroonian adults with uncomplicated malaria followed longitudinally for 5 visits over up to 37 days post-treatment. At each visit, participants underwent Cytophone, microscopy, a pan-species rapid diagnostic test, and highly-sensitive molecular testing. Compared to microscopy, Cytophone had a sensitivity, specificity, and receiver operating characteristic area under the curve of 90%, 69%, and 0.84, respectively, indicating excellent diagnostic performance. Using highly-sensitive *var*ATS qPCR as the gold standard, Cytophone had an optimal diagnostic detection cut-off at ≥ 7 parasites/μL and comparable performance to standard POC methods. Following treatment, we noted a clear trend in decreasing PA signals over the follow-up period, with the Cytophone showing similar relative rates of quantitative decrease as microscopy. Additionally, Cytophone detected PA peaks in 2/2 *P. malariae* mono-infection samples, demonstrating the device's ability to detect non-falciparum species. Overall, results of this first proof-of-principle clinical study conducted in an endemic setting demonstrate the potential to rapidly and noninvasively detect malaria infection *in vivo*. Additional device modifications and studies are underway to further optimize this innovative new diagnostic platform.

DROPLET DIGITAL PCR AND SEQUENCING REVEALS CONCURRENT PFHRP2/3 GENE DELETIONS AND KELCH 13 MUTATIONS ACROSS ETHIOPIA

Jack Burke-Gaffney[1], Claire Kamaliddin[1], Aderaw Adamu[2], Shoaib Ashraf[1], Ayesha Wijesinghe[1], Enaara Pussegoda[3], Daniel Castaneda Mogollon[1], Sindew Mekasha Feleke[2], **Dylan R. Pillai**[1]

[1]University of Calgary, Calgary, AB, Canada, [2]Ethiopia Public Health Institute, Addis Ababa, Ethiopia, [3]University of Western Australia, Perth, Australia

Test-treat-track (TTT) approach to eradicate malaria relies on the detection of Histidine-Rich Proteins 2/3 (HRP2/3) through rapid diagnostic tests (RDTs), followed by treatment with artemisinin-combination therapies (ACT). However, data suggest that in the Horn of Africa alone *hrp2/3* deletions resulted in up to 50% of to be missed by RDTs. Recent reports of kelch13 mutations suggest resistance conferring single nucleotide polymorphisms are widespread. Our group was the first to document kelch13 R622I in Ethiopia in 2014. If these hrp2/3 deletions and kelch 13 mutations were to occur together this would jeopardize malaria elimination. To describe the interplay between diagnostic- and drug-resistance in *P. falciparum* species, 217 *P.falciparum* malaria infections randomly selected from 7 regions representative of Ethiopia were evaluated for *hrp2/3* deletions using qualitative PCR and quantitative by digital droplet PCR (ddPCR). Sequencing of *kelch13* was assessed to identify kelch 13 mutations associated with artemisinin-resistance. The preliminary results (n=42) demonstrate that with PCR, 11/42 (26%) were *hrp2* negative, 33/42 (79%) were *hrp3* negative and 11/42 (26%) were both *hrp2/3* negative. However, with ddPCR, 10/42 (23%) samples were negative for both *hrp2* exon 1 and 2, 32/42 (76%) negative for *hrp3*, while 9/42 (21%) were negative for both *hrp2/3*. 18/42 (43%) samples had 1 or more mutations in *kelch13*. 9/42 (21%) of infections contained either polyclonal infections or partial deletions by ddPCR. A significant proportion 9/42 (21%) of samples contained *hrp2/3* deletions combined with *kelch13* mutations ($P = 0.0573$). Further analysis of the remaining samples will confirm whether there is significant correlation between the deletions in *hrp2/3* and the *kelch13* mutations. Our study raises the spectre of co-selection of drug and diagnostic resistance in *P. falciparum* malaria. The completed study results will be presented at ASTMH.

5016

MULTIPLEX MICROFLUIDIC CARTRIDGE 'MICROLAMP' FOR MALARIA DETECTION AND SPECIATION

Hitendra Kumar, **Nabil Royez**, Jack Burke-Gaffney, Keekyoung Kim, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

In clinical settings, patients are often misdiagnosed and do not receive correct timely treatment. Rapid multiplexed tests comprising variants of the infectious diseases can be pivotal in identifying the infections and enhance the physician's ability to diagnose use appropriate treatment and avoid misusage of drugs. Point-of-care tests (POCTs) with rapid and accurate diagnosis are need. Loop mediated amplification (LAMP) significantly reduces detection time with a simplified sample preparation step and a rapid amplification step under isothermal conditions. For widespread usage, POCTs must be simple to perform with minimal technical expertise biosafety and provide diagnosis within 30 minutes. We have developed a microfluidic cartridge based POCT for malaria diagnosis. The cartridge is constructed with a multilayered architecture forming channels, reservoirs and integrating a porous lateral flow (LF) strip loaded with dry LAMP reagents in a closed system. The LF strip acts as a filter as well as provide passive flow of assay fluids (sample, buffer solutions). The cartridges are loaded on a companion battery-powered reader device comprising a heater for isothermal amplification. A combination of LEDs, optical filter and light-intensity sensors performs a real-time visual fluorescence readout of the LAMP products. A complementary smartphone app provides wireless control over the device components as well as recording the real-time LAMP data to improve diagnosis accuracy. This POCT platform dubbed "MicroLAMP" is coupled with a multiplexed panel for detection and differentiation of malaria parasites using a minimally invasive finger prick blood sample. The POCT tool is broadly applicable to multiple infectious diseases at a low cost.

5017

ACTIVE CASE DETECTION AND TREATMENT OF MALARIA IN PREGNANCY USING LAMP TECHNOLOGY (LAMPREG): A PRAGMATIC RANDOMIZED DIAGNOSTIC OUTCOMES TRIAL

Rediet Fikru[1], Claire Kamaliddin[2], Filmona Mekuria[1], Betelhem Solomon[1], Banchamlak Tegegne[3], Delenasaw Yewhalaw[4], Mekonnen Teferi[1], Abebe G. Bayih[5], **Dylan R. Pillai**[2], LAMPREG STUDY TEAM[2]

[1]Armauer Hansen Research Insitute, Addis Ababa, Ethiopia, [2]University of Calgary, Calgary, AB, Canada, [3]Amhara Public Health Institute, Bahir Dar, Ethiopia, [4]Jimma Univeristy, Jimma, Ethiopia, [5]Armauer Hansen Research Institute, Addis Ababa, Ethiopia

Malaria infection during pregnancy (MiP) leads to low birthweight which is a strong risk factor for neonatal and childhood mortality. Intermittent preventive therapy in pregnancy (IPTP) uptake in sub-Saharan African countries remains low. Diagnosis of MiP is challenged by sub-clinical presentation and low parasitemia. This clinical trial evaluated active detection of MiP using a molecular method for the detection of Plasmodium DNA by loop-mediated isothermal amplification (LAMP) during antenatal care (ANC) in Ethiopia where there is no IPTP. A pragmatic randomized diagnostic outcomes trial was conducted between 2020-3 at three rural hospitals and five health centres. Women are randomized to either the standard of care (SOC, 1/3) or the active case detection arm (LAMP, 2/3) at their first ANC visit and subsequently followed through to delivery. Malaria diagnosis is performed by microscopy and RDT in the SOC arm using Malaria-LAMP (Loopamp™, Human Diagnostica), microscopy, and RDT in the intervention arm. Treatment of women positive for malaria by any method was with Co-artem. In the interim analysis, 2,116 women were enrolled, 715 in the SOC arm and 1401 in the LAMP arm, with 1452 deliveries completed. Malaria detection was superior using LAMP detection with 219 positive (15.6%), compared to 129 (9.2%) and 114 (8.1%) for RDT and microscopy, respectively. In terms of outcomes, the average newborn weight was 47.0g higher in the LAMP arm (3,184g vs. 3,231g, p=0.12). The proportion of LBW newborns was 5.06% (SOC-arm) and 4.24% (LAMP-arm) (p=0.57). Newborn anemia was 3.85% in SOC versus 2.31% in LAMP (p=0.13). Significant reduction in prematurity (12.12% [SOC] versus 5.26% [LAMP], p=<0.0001) and improvement in 28-day newborn weight (4,121g [SOC] versus 4,331g [LAMP], p=<0.0001) was observed with LAMP. Molecular diagnosis of malaria with LAMP detected almost double the number of MiP compared to standard microscopy and RDT, resulted in improved absolute birth weight, lower incidence of LBW, less newborn anemia, less prematurity and improved 28-day newborn weight. Final results of this major clinical diagnostics trial will be presented at ASTMH.

NEW THYMIDINE KINASE-IN DEPENDENT CLICK CHEMISTRY DNADETECT™ PROBES FOR ASSESSMENT OF DNA PROLIFERATION IN MALARIA PARASITES

David H. Hilko, Gillian M. Fisher, **Katherine Andrews**, Sally-Ann Poulsen

Griffith University, Nathan, Australia

The alkyne modified thymidine analogue 5-ethynyl-2′-deoxyuridine (EdU) is a gold standard chemical probe for detection of DNA synthesis and proliferation in mammalian cells. EdU exploits the thymidine salvage pathway to incorporate into nuclear DNA, followed by detection via copper catalysed azide-alkyne cycloaddition (CuAAC) with a fluorescent azide. However, a limitation of EdU (and similar probes like BrdU) is that some organisms, including *Plasmodium* malaria parasites, lack the thymidine kinase enzyme that is essential for metabolism. While *P. falciparum* with

an introduced thymidine kinase from *Herpes simplex* virus has been successfully used in DNA labelling studies using BrdU and EdU, this approach may not be feasible for analysis different *Plasmodium* species, multiple laboratory lines and field isolates. To overcome this, we have designed and synthesised new thymidine-based probes that overcome the need for an endogenous thymidine kinase enzyme. Using CuAAC with a fluorescent azide and flow cytometry, we have shown that these DNADetect™ probes robustly label replicating asexual intraerythrocytic *P. falciparum* parasites, while EdU as a control failed to label parasites. The DNADetect™ chemical probes are synthetically accessible and thus have broad applicability as tools to further understand the biology of different *Plasmodium* species, including laboratory lines and clinical isolates.

USE OF MINIMALLY INVASIVE TISSUE SAMPLING (MITS) TO DETERMINE THE CONTRIBUTION OF MALARIA INFECTIONS TO MORTALITY IN CHILDREN UNDER 5 YEARS OF AGE IN THE CHAMPS NETWORK

Ikechukwu U. Ogbuanu[1], Kephas Otieno[2], Rosauro Varo[3], Zachary Madewell[4], Beth A. Tippett Barr[5], Inacio Mandomando[6], Dianna M. Blau[4], Cynthia G. Whitney[7], Aaron M. Samuels[4], **Quique Bassat**[3]

[1]Crown Agents in Sierra Leone, Freetown, Sierra Leone, [2]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [3]ISGlobal, Barcelona, Spain, [4]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Nyanja Health Research Institute, Salima, Malawi, [6]Centro de Investigaçao em Saude de Manhiça, Manhiça, Mozambique, [7]Emory Global Health Institute, Emory University, Atlanta, GA, United States

Background Malaria remains a major killer of children globally, but accurately quantifying endemic country estimates is difficult as current tools lack sensitivity. Such estimates are needed to prioritize targeting of commodities and interventions.Methods Seven sites in Africa and Asia participating in Child Health and Mortality Prevention Surveillance (CHAMPS) collected comprehensive data from stillbirths and children <5 years of age within their catchment areas. Minimally invasive tissue sampling (MITS) was performed on those enrolled within 24 hours of death. Underlying, intermediate, and immediate causes of death (CoD) were assigned by local expert panels, utilizing sociodemographic, clinical, laboratory, and verbal autopsy data according to standardized protocols. The expert panel also determined if the death could have been prevented with existing, recommended measures. Analyses were conducted in 4 sites with high malaria endemicity (Mozambique, Kenya, Sierra Leone and Mali) to describe factors associated with malaria-related deaths, estimate malaria-specific mortality, and assess the proportion of preventable deaths in 1 to <60 month-olds.Findings Between 2016-2022, MITS was used to determine CoD for 773 infant and child deaths. Malaria played a significant role in the causal pathway in 237 (30.7%), 75.7% of which were aged 12-<60 months. Of all malaria deaths, 24.9% occurred in the community, 16.0% were medically unattended, and 98.7% were determined to be preventable. *P. falciparum* was the sole infecting pathogen in 164 (69·2%) of the malaria-related deaths: Bacterial co-infections were in the causal pathway of 24·5%, viral co-infections in 13.1%, and malnutrition in 30.5% of the cases. InterpretationMalaria remains a significant cause of childhood deaths in the malaria-endemic sites of CHAMPS despite available treatments and prevention measures. Importantly, one in 4 malaria deaths also had a bacterial co-infection, supporting the use of antibiotics in severe malaria patients.

5020

ALTERED IL-7/IL-7R SIGNALING IN CD4+ T CELLS FROM PATIENTS WITH ACTIVE VISCERAL LEISHMANIASIS

Shashi Kumar[1], Shashi Bhushan Chauhan[2], Shreya Upadhyay[1], Siddharth Sankar Singh[3], Rajiv Kumar[1], Christian Engwerda[4], Susanne Nylen[5], Shyam Sundar[1]

[1]Banaras Hindu University, Varanasi, India, [2]George Washington University, Washington, WA, United States, [3]University of Massachusetts Chan Medical School, Varanasi, MA, United States, [4]QIMR Berghofer Medical Research Institute, Brisbane, Australia, Brisbane, Australia, [5]Karolinska Institutet, Stockholm,, Sweden

CD4+ T cells play an important role in controlling L. donovani infection, through IFN-γ, required for activation of macrophages and killing of intracellular parasites. However, CD4+ T cell effector functions are hampered in visceral leishmaniasis (VL) patients. In a recent study that defined a transcriptional signature for CD4+ T cells from active VL patients, we found that expression of the IL-7 receptor (IL-7R, (CD127) was downregulated, compared to CD4+ T cells from endemic controls (ECs). Since IL-7/IL-7R signaling is critical for the survival and homeostatic maintenance of CD4+ T cells, we investigated the role of this signaling pathway in active VL patients, relative to ECs. CD4+ T cells were enriched from peripheral blood collected from VL and EC subjects and expression of IL7 and IL-7R mRNA was measured by real time qPCR. IL-7 signaling potential and surface expression of CD127 and CD132 on CD4+ T cell and various cell subsets was analyzed by multicolor flow cytometry. Plasma levels of soluble IL-7 and IL-7R were measured by ELISA. In line with previous findings, we found reduced IL7R mRNA expression in CD4+ T cells as well as reduced soluble IL-7R in plasma of VL patients. However, plasma levels of soluble IL-7 were higher in VL patients. Interestingly, expression of the IL-7R was higher on VL CD4 T cells as compared to EC, with activated CD38+ CD4+ T cells showing higher surface expression of IL-7R (CD127 and CD132), compared to CD38- CD4+ T cells in active VL patients. CD4+ T cells from VL patients had higher signaling potential after stimulation with recombinant IL-7 compared to EC, as measured by phosphorylation of STAT5. Thus, despite reduced IL7R mRNA expression in CD4+ T cell from VL patients, surface express of IL-7R was higher and increased phosphorylated STAT5 was seen following exposure to IL-7. Thus, despite lower IL-7mRNA expression, IL-7 signaling appears to be functional and even enhanced in VL CD4 cells and cannot explain the impaired effector function of VL CD4 T cell. The enhanced plasma IL-7 may have caused reduced IL7R transcription by CD4+ T cells as a part of homeostatic feedback mechanism.

5021

DECONSTRUCTING TRANSMISSION OF VISCERAL LEISHMANIASIS THROUGH ANALYSIS OF BLOOD FED SAND FLIES

Patrick Allen Huffcutt[1], Khushbu Priyamvada[2], Pushkar Dubey[2], Joy Bindroo[2], Asgar Ali[2], Asahar Alam[2], Shalini Singh[2], Mohammad Shahnawaz[2], Debanjan Patra[2], Indranil Sukla[2], Avneesh Kumar[2], Gaurav Kumar[2], Pankaj Kumar[2], Shani Pandey[2], Claudio Meneses[1], Jesus G. Valenzuela[1], Sridhar Srikantiah[2], Caryn Bern[3], Tiago Donatelli Serafim[1], Eva Iniguez[1], Shaden Kamhawi[1]

[1]National Institutes of Health, Laboratory of Molecular Vector Research, Rockville, MD, United States, [2]CARE India Solutions for Sustainable Development, Patna, India, [3]University of California, San Francisco, CA, United States

Visceral leishmaniasis (VL) is a vector-borne neglected parasitic disease transmitted by sand fly bites. VL causes up to 90,000 new cases per year and has a fatality rate of 95% without treatment. In India, VL is nearing elimination, yet disease outbreaks continue to occur. With many features of VL transmission not well understood, partly due to disease focality that is influenced by local environment, sand fly behavior, and human density and activity, in-depth analysis of field collected blood fed female sand flies can offer valuable insights into the dynamics of VL transmission. In addition to understanding host preference, we hypothesize that linking the source of the sand fly blood meal to *Leishmania* infection status and burden will shed light on the directionality of parasite transmission and point to potential infection reservoirs in a natural setting. To achieve this, we are developing tools using single sand flies experimentally fed on blood of various animals, spiked or not with *Leishmania donovani*. We dried the dissected midgut of individual blood fed female sand flies onto Whatman 903 protein saver card filters, used for specimen preservation in the field, and optimized DNA recovery to an average of 200-300ng per specimen; enough to run several concurrent assays. Using a sensitive Taq-Man probe-based

qPCR targeting kinetoplast DNA, we successfully detected and quantified *Leishmania* parasites from single infected guts. We also obtained strong amplification from single flies fed on human, goat, cow, pig, and dog blood using a multiplex PCR for blood meal analysis based on the mitochondrial cytochrome c oxidase subunit one gene, and we are currently testing others. After completing laboratory optimization, we will validate these tools in VL outbreak villages in India. This toolbox can be adapted to specific leishmaniasis foci for greater understanding of sand fly behavior in a field setting. Using established techniques to address epidemiologically relevant questions can enhance our understanding of leishmaniasis transmission within human communities and improve policy-making decisions towards better vector-control programs.

NEUTROPHILS IN PATHOGENESIS OF POST KALA-AZAR DERMAL LEISHMANIASIS (PKDL), FRIEND OR FOE?

Madhurima Roy

Institute of Post Graduate Medical Education & Research, Kolkata, India

Post Kala-azar Dermal Leishmaniasis, a sequel of apparently cured Visceral Leishmaniasis, presents in South Asia with papulonodular (polymorphic) or hypomelanotic lesions (macular). Neutrophils are the first line of defense in VL and facilitate disease establishment by serving as 'trojan horses'. However, knowledge regarding a biological role, if any, for neutrophils in PKDL is limited. This study aimed to delineate the status of neutrophils at the dermal lesions of PKDL, and their possible functionalities. Accordingly, the presence of lesional CD66b$^+$ neutrophils along with their functional status was assessed by immunofluorescence/ immunohistochemistry in terms of activation (CD66b$^+$/CD64$^+$), degranulation (CD66b$^+$/MPO$^+$), release of neutrophil elastase (NE) and matrix metalloprotease 9 (MMP9) along with their transcriptomic profile using the Visium (10X) platform. The levels of circulating neutrophil chemo-attractants CXCL8, CXCL1/2/5, CCL2 and 20, along with cytokines, IL-6, IFN-γ, IL-4, IL-10, TNF-α, IL-17 and IL-23 as markers for inflammation were evaluated by a multiplex assay. As compared to skin from healthy individuals, PKDL cases demonstrated an increased infiltration of activated neutrophils (increased CD64$^+$, MPO, NE). There was an increase in plasma levels of neutrophil chemo-attractants, along with pro-inflammatory and regulatory cytokines. Levels of MMP9 were elevated in both circulation and at lesional sites, with concomitant collagen I degradation. However, the tissue damage was moderate, perhaps owing to the concomitant increase in expression of *TIMP1.* The immune responses constituted a mixed Th1 (IFN-γ, IL-6), Th2 (IL-4) and Treg (IL-10) profile, with a conspicuous absence of the Th17 phenotype. The increased levels of CXCL8 and CXCL5 correlated with the proportion of infiltrated neutrophils; furthermore, this homing was IL-10 dependant. Taken together, in PKDL, a chronic dermatosis, the presence of activated neutrophils at lesional sites suggested its permissive role(s) in modulating the lesional landscape and facilitating disease progression.

5023

ALTERED PROFILE OF CD4+T CELLS CHEMOKINE RECEPTOR EXPRESSION DURING VISCERAL LEISHMANIASIS

Shreya Upadhyay[1], Shashi Kumar[1], Shashi Bhushan Chauhan[2], Siddharth Sankar Singh[3], Susanne Nylen[4], Christian Engwerda[5], Rajiv Kumar[1], Madhukar Rai[1], Shyam Sundar[1]

[1]Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, [2]George Washington University, Washington, WA, United States, [3]University of Massachusetts Medical School, Worcester, MA, United States, [4]Karolinska Institutet, Stockholm, Sweden, [5]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Robust Th1 cell responses, which activate macrophages to kill intracellular parasites, are required to control Leishmania infection. Yet, VL patients do not control the infection despite expansion of CD4$^+$ T cells and increased IFNγ expression in the spleen. Chemokines &/or chemokine receptors are involved in cellular migration & are critical in the inflammatory response. In a recent study that defined a transcriptional signature for CD4$^+$ T cells from active VL patients, we found several differentially expressed chemokine receptor genes compared to CD4$^+$ T cells of healthy endemic controls (HEC). Since CD4$^+$ T cell plays crucial roles in parasite clearance, there is need to understand the role of altered chemokine receptor expression on CD4$^+$ T cells & their different subsets. In this study, we validated the gene expression & surface protein expression of differentially expressed chemokine receptors found in human VL subjects compared to HEC by real-time qPCR and multicolor flow cytometry, respectively. We found elevated mRNA & surface protein expression of CCR5, while reduced CCR4 & CCR6 expression in VL patients CD4$^+$ T cells. CCR5 was upregulated on Th1 cell subsets indicating the expansion of CCR5$^+$ Th1 cells in peripheral blood that may be responsible for Th1 cells trafficking towards the infected tissue. CCR4 expression was reduced on regulatory T cells (Treg) & central memory T cells (Tcm) suggesting reduced frequencies of these cells in peripheral blood during VL. Our results suggest that VL patients possess unique chemokine receptor expression on their surface compared to healthy subjects. The implications of these finding have on VL pathogenesis & how the knowledge of these changes can provide direction for the development of new and improved therapeutic approach against VL is under investigation.

A POTENTIAL ROLE FOR ADIPOCYTES IN VISCERAL LEISHMANIASIS

Patrick Kwadwo Nuro-Gyina, Bayan Zhanbolat, Yani Chen, Carter R. Dwyer, Jacilara Alexandrino-Conceicao, Aloysius Klingelhutz, Mary Wilson

University of Iowa, Iowa City, IA, United States

Leishmaniasis is a chronic parasitic disease in which parasites are found in host macrophages throughout the reticuloendothelial organs. Recent data indicate that many cells not thought of traditionally as immune cells contribute to the cytokine/chemokine environment locally where the parasite survives, and to the systemic immune responses. Adipocytes are versatile cells whose functions in systemic energy homeostasis and as reservoir for excess energy are well documented. Adipocytes are present in subcutaneous tissues near the parasite inoculum, but their potential involvement in immunoregulation of leishmaniasis is unknown. To determine whether and how adipocytes interact with the *Leishmania* species, we differentiated human preadipocytes into adipocytes and incubated them with *L. infantum, L. major* or *L. braziliensis* promastigotes. We found that the *Leishmania spp.* parasites were taken up by human adipocytes and transformed morphologically to the intracellular amastigote form, but this occurred differently between the species. *L. infantum* was taken up by 20.0% of adipocytes, whereas *L. major* or *L. braziliensis* were taken up by 11.5 or 4.8% of adipocytes, respectively. None of the parasite species replicated intracellularly over 48 hrs. RT-qPCR for candidate immunoregulatory transcripts revealed up-regulation of the IL6 and PPARγ but down-regulation of genes involved in lipogenesis such as Adiponectin, Lipoprotein lipase and Leptin receptor. There were quantitative, but no apparent qualitative differences between the species. These data suggest a potential role for adipocytes in *Leishmania* spp. infection, although the roles may differ between different *Leishmania* species.

5025

IMMUNE MODULATION INDUCED BY LEISHMANIA EUKARYOTIC INITIATION FACTOR BEFORE LEISHMANIA INFANTUM INFECTION OF THP1 DERIVED MACROPHAGES

Imen Bassoumi Jamoussi, Yosser Zina Abdelkrim, Ons Zakraoui, Rafeh Oualha, Mourad Barhoumi, Khadija Essafi Benkhadir, Ikram Guizani

Institut Pasteur De Tunis, Tunis, Tunisia

Leishmaniases are a complex group of neglected infectious diseases of poverty, and serious public health problems. Development of novel control strategies remains a research priority. *Leishmania* Eukaryotic Initiation Factor (LelF) antigen is a natural Th1 type natural adjuvant that stimulates

cytokine expression in healthy and infected cells. We showed LelF induces resistance of J774 mice cells to *L. donovani* infection. We investigate here the effect of LelF on infection of human macrophages by *Leishmania infantum*. To model macrophage-parasite interaction *in vitro*, we used THP-1-derived macrophages (TDMs) and *L.infantum* strain. Infection conditions as multiplicity of infection, incubation and readout time were set by light microscopy. The optimal protein amount that was not cytotoxic and did not affect TDMs viability was selected based on LDH and MTT assays, respectively. Cells were treated before the infection with recombinant LelF protein and its effect on infection was measured on Giemsa-stained slides. The presence of microbicidal molecules such as Nitric Oxide and reactive oxygen species in culture supernatant was determined. Levels of secreted cytokines were quantified by multiplex flow cytometry. We found that a MOI of 10 parasites per cell leads to 70% of infected cells and up to 6 intracellular amastigotes/cell with an optimal infectivity at 24h time post infection. With LelF pre-treatment, infectivity of TDMs decreased to 39% and parasite load to a mean of 2 amastigotes/cell. Parasitic Index of untreated infected TDMs were found to be 420, this value decreased to 80 for LelF treated cells; the effect was shown to be specific to live parasites (vs killed parasites or latex beads). This result indicated that LelF induced cell resistance to *L.infantum* infection (80% parasitic index inhibition). Such an effect was proven to be associated with the accumulation of ROS and a significant release of pro-inflammatory cytokines such as IL-8, TNF-α, IL-6 and IL-1β. The study confirms the prophylactic potential of LelF in another pathogen-cell model and open ways to understand mechanisms involved in the cell response to LelF immune modulation.

CATALASE IS DETRIMENTAL FOR LEISHMANIA VIRULENCE (WITH NOTES ON EVOLUTION OF CATALASES IN TRYPANOSOMATIDAE)

Vyacheslav Yurchenko[1], Ľubomíra Chmelová[1], Natalia Kraeva[1], Petr Volf[2], Jovana Sádlová[2]

[1]University of Ostrava, Ostrava, Czech Republic, [2]Charles University, Prague, Czech Republic

Catalase is one of the most abundant enzymes on Earth. It decomposes hydrogen peroxide, thus protecting cells from dangerous reactive oxygen species. The catalase-encoding gene is conspicuously absent from the genome of most representatives of the family Trypanosomatidae. The exceptions are monoxenous relatives of *Leishmania* spp., and representatives of the genera *Blastocrithidia*, *Obscuromonas*, and *Vickermania.* In this work, we expressed the *Leptomonas seymouri*-derived catalase from the *Leishmania mexicana beta-tubulin* locus using a novel bi-cistronic expression system, which relies on the 2Apeptide of *Teschovirus A*. We demonstrated that catalase-expressing parasites are severely compromised in their ability to develop in insects, to be transmitted and to infect mice, and to cause clinical manifestation in their mammalian host. Taken together, our data support the hypothesis that the presence of catalase is not compatible with the dixenous life cycle of *Leishmania*, resulting in loss of this gene from the genome during evolution of these parasites. To complement these data, we ablated a catalase-encoding gene from the *Leptomonas seymouri* genome and established an add-back, where catalase was overexpressed from the 18S rRNA locus of *L seymouri*. Our study demonstrated that parasites' development and infectivity *in vivo* (in *Dysdercus peruvianus* model) depends on the expression level of this enzyme. These studies were further complimented by biochemical characterization of three independently-acquired catalases (of *Blastocrithidia*, *Leptomonas*, and *Vickermania*) *in vitro*, which showed that the enzyme of *Blastocrithidia nonstop* is cyanide-resistance, an unprecedented feature among all investigated monofunctional catalases.

GEOSPATIAL ANALYSIS OF THE DISTRIBUTION OF HYMENOLEPIS NANA INFECTION AMONG CHILDREN'S HOUSEHOLDS AND SCHOOLS OF THE PROVINCE OF ANTA, PERU

Melinda B. Tanabe[1], Maria Alejandra Caravedo Martinez[1], Maria Luisa Morales[2], Martha Lopez[2], Benicia Baca-Turpo[2], Eulogia Arque Sollace[2], Miguel M. Cabada[3]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Alexander von Humboldt Tropical Medicine Institute, UPCH, Cusco, Peru, [3]UPCH – UTMB Collaborative Research Center - Cusco, Universidad Peruana Cayetano, Cusco, Peru

Hymenolepis nana is an emergent parasitosis in the Cusco region associated with morbidity in children of rural communities. We used data from a cross-sectional study evaluating children for gastrointestinal parasites in the Anta province in Peru. We geographically tagged the children's residences and respective schools. Stool was evaluated by rapid sedimentation and Kato Katz microscopy. Local distribution patterns of infection were identified via Anselin local Moran's I and Getis-Ord Gi* statistics. A total of 2961 children were included from 51 schools. The mean age was 9.7 years old (± 3.55), 1479 (50%) were female, and the median HAZ was -1.4 (IQR -2 to -0.8). The median H. nana prevalence per school was 15% (IQR 3.61 - 24.20), 915 (30.9%) children were infected with > 1 parasite, and 420 (14.4%) of the households had at least one child infected with H. nana. Mapping of hymenolepiasis distribution of hot and cold spots (p< 0.10) geographically differed between schools and households. Logistic regression analysis showed that infected children residing in areas of high geospatial risk of infection had lower HAZ score (OR 2.725 95%CI 1.162-0.828, p= 0.016) and had mothers with fewer years of education (OR 0.859, 95% CI 0.744 - 0.992, p=0.039) compared to uninfected children residing in similar areas. When comparing schools located in hot vs cold spots, children attending schools in hot spots locations were younger (OR 0.882, 95% CI 0.812-0.958, p= 0.003), were more likely to have anemia (OR 1.873, 95% CI 1.198-2.928, p=0.006), had lower HAZ score (OR 0.795, 95% CI 0.669-0.944, p=0.009), lived at higher altitudes (OR 1.009, 95%CI 1.007-1.011, p = < 0.001), had fathers with fewer years of education (OR 0.928, 95%CI 0.866 - 0.973, p= 0.002), and had other parasitic infections (OR 1.513, 95% CI 1.099- 2.085, p= 0.011). Our data demonstrated clustering of H. nana infections in schools and residences suggesting school and household transmission. Information provided could be used for local health authorities to develop strategies for infection control.

ACUTE KIDNEY INJURY IN CHILDREN WITH SICKLE CELL ANEMIA IS LINKED TO TUBULOINTERSTITIAL INJURY AND MICROCIRCULATORY DYSFUNCTION

Rodney Ogwang[1], Ivan Mufumba[1], Caroline Kazinga[1], Anthony Batte[2], Andrea Conroy[3]

[1]Global Health Uganda, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]University of Indiana, Indiana, IN, United States

Acute kidney injury (AKI) is common in hospitalized children, including patients with sickle cell anemia (SCA). AKI is a diverse clinical syndrome and the pathophysiology of AKI in children with SCA associated AKI is not well understood. Here we investigated immune pathways associated with AKI in 185 children with SCA hospitalized for a vaso-occlusive pain crisis and 65 children with SCA in steady state as controls. AKI was defined in hospitalized children using the KDIGO definition as ≥ 1.5-fold change in creatinine within seven days or an absolute change of ≥ 0.3 mg/dl within 48 hours excluding children with a 1.5-fold change in creatinine from 0.2 mg/dL to 0.3 mg/dL. Using ELISA, we measured serum levels of markers of kidney structure and function (cystatin C, neutrophil gelatinase associated lipocalin [NGAL], renin), tubulointerstitial stress and inflammation (tissue inhibitors of metalloproteinases 1 [TIMP-1], interleukin-18 [IL-18]) and microcirculatory dysfunction (P-selectin, angiopoietin-2 [Angpt-2], and

soluble fms-like tyrosine kinase 1 [sFlt-1]). The median age of children enrolled was 8.9 years (IQR, 2.7 to 11.8) and 42.8% of participants were female. Compared to steady state controls, children hospitalized with a pain crisis had higher levels of NGAL, increases in markers of tubulointerstitial stress (TIMP-1) and microcirculatory dysfunction (Angpt-2 and sFlt-1) ($p< 0.0001$ for all) but no changes in markers of kidney function or inflammation. Among the 36.2% of children with AKI, there were significant increases in all biomarkers except for P-selectin. Similarly, all biomarkers except P-selectin increased with the severity of AKI (p trend <0.001) and were elevated among children who died ($p<0.05$). Children with SCA hospitalized with a pain crisis exhibit increases in markers of tubulointerstitial stress and structural kidney injury as well as endothelial activation. These pathways are further elevated in children with AKI, increase with worsening kidney function, and are associated with mortality. Additional studies are needed to develop kidney-protective interventions within this at-risk population.

5029

TEMPORAL TRENDS OF BLOOD GLUCOSE IN CHILDREN WITH CEREBRAL MALARIA

Kennedy M. Chastang[1], Rami Imam[2], Meredith G. Sherman[3], Ronke Olowojesiku[4], Amina M. Mukadam[5], Karl B. Seydel[6], Alice M. Liomba[7], John R. Barber[8], Douglas G. Postels[9]

[1]Howard University, Washington, DC, United States, [2]The George Washington University School of Medicine, Washington, DC, United States, [3]Global Health Initiative, Children's National Medical Center, Washington, DC, United States, [4]Department of Pediatrics, Children's National Medical Center, Washington, DC, United States, [5]University of Washington, Seattle, WA, United States, [6]Michigan State University, East Lansing, MI, United States, [7]Blantyre Malaria Project, Blantyre, Malawi, [8]Division of Biostatistics and Study Methodology, Children's National Research Institute, Washington, DC, United States, [9]Division of Neurology, Children's National Medical Center, Washington, DC, United States

Hypoglycemia, defined as a blood glucose <2.2 mmol/L, is associated with death in pediatric cerebral malaria (CM). The optimal duration of glucose monitoring in CM is unknown. We collected data from 1674 hospitalized Malawian children with CM to evaluate the association between hypoglycemia and death or neurologic disability in survivors. We assessed the optimal duration of routine periodic measurements of blood glucose. Children with hypoglycemia at admission had a 2.87-fold higher odds (95% CI: 1.35-6.09) of death and, if they survived, a 3.21-fold greater odds (95% CI: 1.51-6.86) of sequelae at hospital discharge. If hypoglycemia was detected at 6 hours but not at admission, there was a 7.27-fold higher odds of death (95% CI: 1.85-8.56). The presence of newly-developed hypoglycemia after admission was not independently associated with neurological sequelae in CM survivors. 94.7% of all new episodes of blood sugar below a treatment threshold of 3.0 mmol/L occurred within 24 hours of admission. In those with blood sugar below 3.0 mmol/L in the first 24 hours, low blood sugar persisted or recurred for up to 42 hours. Hypoglycemia at admission or 6 hours afterwards is strongly associated with mortality in CM. Children with CM should have 24 hours of post-admission blood glucose measurements. If a blood glucose less than the treatment threshold of 3.0 mmol/L is not detected, routine assessments may cease. Children who have blood sugar values below the treatment threshold detected within the first 24 hours should continue to have periodic glucose measurements for 48 hours post-admission.

Neurological manifestations are common among ill children in low-income countries. We investigated the prevalence and characteristics of neurological manifestations in neonatal, infant, and child deaths in low-resource settings. The study used data collected as part of Child Health and Mortality Prevention Surveillance (CHAMPS) from December 2016 - July 2022, including clinical information, tissue specimens, and laboratory results to systematically determine the causes of death in under-5 children in Bangladesh, Ethiopia, Kenya, Mali, Mozambique, Sierra Leona and South Africa. A total of 3303 deaths underwent minimally invasive tissue sampling through July 2022. After excluding stillbirths, we assessed 2127 neonatal, infant and child deaths. Over 50% of cases with available clinical information presented with at least one neurological sign or symptom prior to their death, with seizures being the most frequent manifestation in all age groups (40% of children and 30% of neonates). The most common diagnoses were hypoxic events and meningoencephalitis in neonates, and malaria and meningoencephalitis in infants and children. However, the sensitivity of each group of signs and symptoms to predict specific diagnoses was overall very poor (with the highest sensitivity of 31.8% for seizures predicting hypoxic events in neonates), and diagnostic tests, such as lumbar punctures (LP), were only performed in a 17.8% of cases with a final diagnosis of meningoencephalitis. Overall, deaths were considered as potentially preventable in 84.8% of hypoxic events, 85.1% of meningoencephalitis and 97% of cerebral malaria cases. In conclusion, neurological manifestations are very common among sick children prior to death, and clinical presentations overlap significantly among the most common diagnoses in all age groups. Diagnostic tools, such as LPs, are rarely performed in our settings. Innovative tools to assess children with neurological manifestations and the improvement of healthcare systems in low-income countries are necessary to prevent under-5 mortality related to neurological emergencies.

SOLUBLE TRIGGERING RECEPTOR EXPRESSED ON MYELOID CELLS 1 (STREM-1) TO RISK-STRATIFY CHILDREN PRESENTING WITH FEBRILE ILLNESS IN SOUTHERN MOZAMBIQUE

Núria Balanza[1], Bàrbara Baro[1], Sara Ajanovic[1], Andrea M. Weckman[2], Marta Valente[1], Justina Bramugy[3], Anelsio Cossa[3], Kathleen Zhong[2], Elizabeth JA Fitchett[4], Shunmay Yeung[4], Tegwen Marlais[4], Heidi Hopkins[4], David Mabey[4], Kevin C. Kain[2], Quique Bassat[1]

[1]ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, [2]Sandra-Rotman Centre for Global Health, Toronto General Research Institute, University Health Network-Toronto General Hospital, Toronto, ON, Canada, [3]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom

Febrile illnesses are a leading reason for pediatric medical consultations. Most febrile children attending primary care facilities have uncomplicated and self-limited infections, but a small proportion may progress to life-threatening conditions requiring prompt and advanced care. However, early in the course of illness, it is difficult to identify which children are at risk for severe and fatal infections. In resource-constrained settings, this is further complicated by limited health care providers and laboratory services. Here we tested the hypothesis that quantifying plasma biomarkers of immune and endothelial activation at clinical presentation may enhance risk-stratification of febrile children. This study was conducted in the Mozambican pediatric cohort of the FIEBRE study. Between December 2018 and February 2021, febrile children aged 2 months - <15 years were enrolled. We measured plasma levels of Angpt-2, CHI3L1, IL-6, IL-8, sFlt-1, sTNFR1, sTREM-1, suPAR, PCT, and CRP at presentation using Luminex and ELISA. Standard clinical and laboratory parameters were assessed at enrollment, and clinical outcomes were evaluated up to 28 days later. A total of 1,040 children were enrolled and had a plasma sample taken for biomarker measurement. 531 (51.1%) were outpatients and 509 (48.9%) were inpatients. Of these, 19 children died within 28 days. sTREM-1 was associated with 28-day mortality (p<0.001) and showed the best discrimination with an AUROC of 0.840 (95% CI: 0.761 to 0.920). sTREM-1 prognostic accuracy for 28-day mortality was superior to PCT (p=0.045), CRP (p<0.001) and lactate (p=0.011). Combining sTREM-1 with some clinical severity scores or definitions (e.g., LODS, LqSOFA, WHO danger signs) improved their prognostic accuracy. sTREM-1 was also associated with 7-day mortality and length of hospital stay. These findings add evidence for sTREM-1 as a promising biomarker for risk-stratification of febrile illnesses in children in resource-constrained settings.

5032

EFFECT OF POINT-OF-CARE RAPID DIAGNOSTIC TESTS ON ANTIBIOTIC PRESCRIPTION IN PRIMARY HEALTH CARE SETTINGS IN TWO PERI-URBAN DISTRICTS IN GHANA

Alexander Adjei[1], Vida A. Kukula[1], Clement Narh[2], Piero Olliaro[3], Rita Baiden[1]

[1]dodowa health research centre, Accra, Ghana, [2]Fred N. Binka School of Public Health. University of Health and Allied Sciences, Ho, Ghana, [3]FIND, the global alliance for diagnostics, Geneva, Switzerland

The management of febrile illnesses is challenging in low-resource countries. It contributes to antibiotic resistance through inappropriate use from diagnostic uncertainty and limited numbers of point-of-care diagnostic tests. This study aimed to assess the impact of rapid diagnostic tests, clinical algorithms, and communication on clinical outcomes and antibiotic prescriptions, compared to standard-of-care practices, of acute febrile illness at outpatient clinics in Shai-Osudoku and Prampram districts in Ghana. This was an open-label, centrally randomized controlled trial in four health facilities. Participants aged 6 months to 18 years old, with acute febrile illness were randomized to either intervention or control arm. A set of point-of-care diagnostic tests and clinical algorithms were used to guide prescribers in antibiotic prescriptions in the intervention arm while a standard-of-care approach per the Ghana National guidelines was used in the control. Clinical outcomes and adherence to prescriptions were assessed in both arms on day 7 follow-up. A total of 1512 patients were randomized to either the intervention (n=761) or control (n=751) arm. The majority were children under 5 years (76.3%) and male (53.5%). The median age was 2 years and the majority presented with fever (94.4%) and/or cough (64.0%). Overall, the intervention reduced antibiotic prescriptions by 4.7%. In children under 5 years, it reduced by 14.5% (RR 0.855 [0.748, 0.978]); 14.8% in non-malaria cases (RR 0.852 [0.754, 0.963]), and 16% in patients with respiratory symptoms (RR 0.840 [0.732, 0.962]). Almost all participants had favorable outcomes (99.7% vs 99.4%) and high adherence (95.5% vs 96.9%) on day 7 follow-up. In conclusion, the combination of point-of-care diagnostics, clinical algorithms, and communication messages can be used at the primary healthcare level to reduce antibiotic prescriptions among children with acute febrile illness.

5033

ASSESSING THE PORTABILITY OF A PEDIATRIC TELEMEDICINE AND MEDICATION DELIVERY SERVICE TO THE GHANAIAN SETTING: A PILOT STUDY

Katelyn E. Flaherty[1], Molly Klarman[1], Nana Anyimadua Anane-Binfoh[2], Mohammed-Najeeb Mahama[3], Maxwell Osei-Ampofo[4], Taiba Afaa Jibril[5], Ahmed N. Zakariah[3], Eric J. Nelson[1], Torben K. Becker[1]

[1]University of Florida, Gainesville, FL, United States, [2]Korle Bu Teaching Hospital, Accra, Ghana, [3]National Ambulance Service, Accra, Ghana, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]University of Ghana, Accra, Ghana

The impact of an intervention relies on its portability to novel settings. A telemedicine and medication delivery service (TMDS) model has worked to improve pediatric access to nighttime care in Haiti; however, the success of the intervention cannot be extrapolated to novel contexts. To establish portability, the TMDS model, known as MotoMeds, must be evaluated in settings with distinct healthcare infrastructures and burdens of disease. Our objective was to implement MotoMeds TMDS in Ghana to assess the model's operational feasibility and clinical safety in a setting with a nationalized emergency medical service and a high burden of malaria. The TMDS was launched in Ghana on November 16th, 2022, in the low-resource communities of Jamestown and Usshertown in Accra. When children ≤10 years became sick at night, their guardians called MotoMeds and reached National Ambulance Service (NAS) Emergency Medical Technicians (EMTs). EMTs asked the guardians questions per WHO-derived decision-support tools. Severe cases were referred to NAS or hospitals. Non-severe cases were further explored; EMTs gathered histories, symptoms, and exam findings over the phone to determine treatment plans. Treatment plans included rapid diagnostic testing for malaria, medications, fluids, and clinic follow-up. EMTs traveled to households to perform parallel in-person examinations and provide testing and treatment. EMTs consulted local on-call physicians as needed. Follow-up phone calls were performed at 10 days. In the first 3 months, 184 cases were enrolled, and 157 household visits were conducted. Common complaints at the call center included fever (150, 82%), cough (91; 49%), and skin problems (62, 34%). An on-call physician was consulted for 22% (41) of cases. 174 cases (95%) were reached for follow-up. At 10 days, 85% (148) of cases were "Well", 11% (19) of cases were "Improved", 2% (4) were the "Same", and 2% (3) of cases were "Worse". No severe adverse events occurred. Findings to date support the operational feasibility and clinical safety of the TMDS in Ghana; thus suggesting the portability of the TMDS model. Implementation and data collection are ongoing.

5034

SEROLOGIC EVIDENCE OF MARBURG VIRUSES AND A BUNDIBUGYO VIRUS-LIKE EBOLAVIRUS IN MADAGASCAN ROUSETTE BATS

Marana Tso[1], Spencer Sterling[1], Hafaliana Christian Ranaivoson[2], Gwenddolen Kettenburg[2], Angelo Andrianiaina[3], Santino Andry[3], Jean-Michel Héraud[4], Eric D. Laing[1], Cara E. Brook[2]

[1]Uniformed Services University of Health Sciences, Bethesda, MD, United States, [2]University of Chicago, Chicago, IL, United States, [3]University of Antananarivo, Antananarivo, Madagascar, [4]Institut Pasteur de Dakar, Dakar, Senegal

Ebolaviruses and marburgviruses are causative agents of viral hemorrhagic fever diseases with a high case fatality in humans. Historically, outbreaks of marburgviruses have occurred in Central and South Africa, connected to mining or cave-tourism activities in caves where the reservoir species, Egyptian rousette bats (ERBs; Rousettus aegyptiacus), roost. Recent Marburg virus disease outbreaks in Equatorial Guinea, Guinea, and Ghana have highlighted gaps in our current knowledge of Marburg virus (MARV) distribution and at-risk areas for spillover. On Madagascar, a single species of rousette bat, Madagascan rousette, resides. We conducted serology-based biosurevillance to assess whether ebolaviruses and marburgviruses circulate enzootically in Madagascan rousettes. Serum samples from 559 Madagascan rousettes and two other species of fruit bats were tested by a multiplex microsphere-based immunoassay for immunoglobulin (Ig) G reactivity against soluble envelope glycoprotein (GP) ectodomain trimers of filoviruses. Antigen-antibody complexes were detected via Luminex xMAP-based technologies, with IgG levels reported as a median fluorescence intensity. Seropositivity cutoffs were determined with a three-sigma-rule (99.7%) probability distribution of naïve ERB sera and latent cluster analysis of field-collected Madagascan rousette sera. We detected IgG binding antibodies against MARV (7.6%; 43/559), Ravn (RAVV) (13.4%; 74/559), and Bundibugyo virus GP (4.8%; 27/559). Interestingly, 5.5% (31/559) were co-positive for IgG against MARV and RAVV. Serological profiles of Madagascan rousettes suggest the presence and co-circulation of uncharacterized ebolaviruses and marburgviurses. Specific serological footprints in Rousettus species native to Madagascar extends our understanding of the host reservoir-pathogen dynamics, implicating the bat genus Rousettus as a reservoir for marburgviruses. Future research is necessary to determine possible evidence of viral chatter between bats and other wildlife or domestic animals, and spillover risk to humans.

5035

EXPOSURE OF EGYPTIAN ROUSETTE BATS (ROUSETTUS AEGYPTIACUS) AND A LITTLE FREE-TAILED BAT (CHAEREPHON PUMILUS) TO ALPHAVIRUSES IN UGANDA

Rebekah Kading[1], Erin Borland[2], Eric C. Mossel[2], Teddy Nakayiki[3], Betty Nalikka[4], Jeremy P. Ledermann[2], Mary B. Crabtree[2], Nicholas A. Panella[2], Luke Nyakarahuka[3], Amy T. Gilbert[5], Julian Kerbis Peterhans[6], Jonathan S. Towner[7], Brian R. Amman[7], Tara K. Sealy[7], Barry R. Miller[2], Julius J. Lutwama[3], Robert M. Kityo[4], Ann M. Powers[2]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centers for Disease Control and Prevention, Division of Vector-borne Diseases, Fort Collins, CO, United States, [3]Department of Arbovirology, Emerging, and Re-emerging Infections, Uganda Virus Research Institute, Entebbe, Uganda, [4]Department of Zoology, Entomology, and Fisheries Science, Makerere University, Kampala, Uganda, [5]Poxvirus and Rabies Branch, Division of High-Consequence Pathogens, United States Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Negaunee Integrative Research Center, Field Museum of Natural History, College of Arts & Sciences, Roosevelt University, Chicago, IL, United States, [7]Viral Special Pathogens Branch, Division of High-Consequence Pathogens, United States Centers for Disease Control and Prevention, Atlanta, GA, United States

The reservoir for zoonotic o'nyong-nyong virus (ONNV) has remained unknown since this virus was first recognized in Uganda in 1959. Building on existing evidence for mosquito blood-feeding on various frugivorous bat species in Uganda, and seroprevalence for arboviruses among bats in Uganda, we sought to assess if serum samples collected from bats in Uganda demonstrated evidence of exposure to ONNV or the closely related zoonotic chikungunya virus (CHIKV). In total, 652 serum samples collected from six bat species were tested by plaque reduction neutralization test (PRNT) for neutralizing antibodies against ONNV and CHIKV. Forty out of 303 (13.2%) Egyptian rousettes from Maramagambo Forest and 1/13 (8%) little free-tailed bats from Banga Nakiwogo, Entebbe contained neutralizing antibodies against ONNV. In addition, 2/303 (0.7%) of these Egyptian rousettes contained neutralizing antibodies to CHIKV, and 8/303 (2.6%) contained neutralizing antibodies that were nonspecifically reactive to alpha-viruses. These data support the interepidemic circulation of ONNV and CHIKV in Uganda, although Egyptian rousette bats are unlikely to serve as reservoirs for these viruses given the inconsistent occurrence of antibody-positive bats.

SPATIAL VARIATION IN NIPAH VIRUS SEROPREVALENCE AMONG PTEROPUS MEDIUS BATS IN BANGLADESH

Ausraful Islam[1], Spencer Sterling[2], Clifton McKee[3], Mohammad Enayet Hossain[1], Mohammed Ziaur Rahman[1], Md. Jahidul Kabir[4], Eric D. Laing[2], Peter Hudson[5], Raina Plowright[6], Emily S. Gurley[3]

[1]icddr,b, Dhaka, Bangladesh, [2]Uniformed Services University of the Health Sciences, Maryland, MD, United States, [3]Johns Hopkins University, Maryland, MD, United States, [4]Bangladesh Forest Department, Dhaka, Bangladesh, [5]The Pennsylvania State University, Pennsylvania, PA, United States, [6]Cornell University, New York, NY, United States

The Indian flying fox, Pteropus medius, is the known reservoir for the Nipah virus (NiV) in Bangladesh, causing spillovers into humans every year. Previous studies of bat roost nearby human cases demonstrated that viral shedding is rarely detected and that prevalence of IgG antibodies against NiV in these flying foxes varied from 14-60%. Many questions remain about the ecology of this virus, including whether spatial and temporal differences in spillover are associated with differences in transmission or behaviors among reservoir hosts. During 2019-2022, we investigated seroprevalence and NiV shedding among flying foxes in Bangladesh at four roosts: one large roost (Cox's Bazar>2000) outside NiV spillover areas, and one large (Faridpur>2000) and two smaller roosts (Naogaon and Rangpur<1000) nearby spillover sites. Once per month, we collected throat and urine swabs and a blood sample from 100-200 bats. We used a multiplex immunoassay to detect antibodies against the receptor-binding protein from NiV virus and four other species of Henipavirus (Hendra, Cedar, Mojang, and Ghana virus) and rRT-PCR to detect viral shedding in swabs. We sampled 3023 bats; overall, NiV seroprevalence was 14% and 5 bats (<0.01%) were found to be actively shedding NiV. Seroprevalence was similar between the two large roosts (17% vs 19%), nearby and far away from spillover sites. However, two smaller roost sites nearby spillover areas had much lower seroprevalence (6% in Naogaon and 5% in Rangpur) than larger roosts, suggesting that NiV transmission within bat roosts may be influenced by population size. Investigations into bat movement between roosts and bat feeding behavior differences by roost size could further explain how roost size may contribute to these patterns. Although none of the other henipaviruses included in the immunoassay circulate in bats in Bangladesh, many individual bat antisera were co-positive with those antigen targets, suggesting that other unknown henipaviruses may circulate in these bats. Given the human health risks posed by NiV, describing the other henipaviruses that may circulate in these reservoir hosts should be a research priority.

CENCURUT VIRUS: A NOVEL ORTHONAIROVIRUS FROM ASIAN HOUSE SHREWS (SUNCUS MURINUS) IN SINGAPORE

Dolyce Hong Wen Low[1], Lena Ch'ng[1], Yvonne Su[1], Martin Linster[1], Rong Zhang[1], Yan Zhuang[1], Mackenzie Kwak[2], Sophie Borthwick[1], Alan Hitch[3], Gavin Smith[1], Ian Mendenhall[1]

[1]Duke-NUS Medical School, Singapore, Singapore, [2]Hokkaido University, Sapporo, Japan, [3]University of California, Davis, CA, United States

Orthonairovirus is a genus of viruses in the family Nairoviridae, order Bunyavirales, with a segmented circular RNA genome. They typically infect birds and mammals and are primarily transmitted by ectoparasites such as ticks. Four of nine Orthonairovirus genogroups can infect humans, with Crimean-Congo hemorrhagic fever virus infections displaying case fatality rates up to 40%. Here, we discover and describe a novel Orthonairovirus as Cencurut virus (CENV). CENV was detected in 34 of 37 Asian house shrews (Suncus murinus) sampled in Singapore and in a nymphal Amblyomma helvolum tick collected from an infected shrew. Pairwise comparison of CENV S, M, and L segments had 95.0 to 100% nucleotide and 97.5 to 100% amino acid homology within CENV genomes, suggesting a diverse viral population. Phylogenetic analysis of the individual gene segments showed that CENV is related to Erve, Lamusara, Lamgora, and Thiafora viruses, with only 49.0 to 58.2% nucleotide and 41.7 to 61.1% amino acid homology, which has previously been detected in other shrew species from France, Gabon, and Senegal respectively. The high detection frequency suggests that CENV is endemic among S. murinus populations in Singapore. The discovery of CENV, from a virus family with known zoonotic potential, underlines the importance of surveillance of synanthropic small mammals that are widely distributed across Southeast Asia.

EPIDEMIOLOGY AND GENETIC DIVERSITY OF NOVEL PARAMYXOVIRUSES RELATED TO LANGYA VIRUS IN RODENTS AND SHREWS IN BANGLADESH

Ariful Islam[1], Md Ziaur Rahman[2], Shariful Islam[3], Melinda K Rostal[1], Mohammad Enayet Hossain[4], Md Kaisar Rahman[3], Emily Hagan[1], Monjurul Islam[3], Tahmina Shirin[3], Meerjady Sabrina Flora[3], Simon J Anthony[5], Peter Daszak[1], Jonathan H Epstein[1]

[1]EcoHealth Alliance, New York, NY, United States, [2]One Health laboratory, International center for diarrheal disease research (icddr,b), Dhaka, Bangladesh, [3]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh, [4]One Health laboratory,International center for diarrheal disease research (icddr,b), Dhaka, Bangladesh, [5]Department of Pathology, Microbiology, and Immunology, University of California-Davis School of Veterinary, California, CA, United States

Rodents and shrews live in close proximity to humans and have been identified as critical hosts of zoonotic pathogens. As part of a broad One Health surveillance effort, we conducted surveillance for novel zoonotic viruses in wildlife, domestic animals, and people. Paramyxoviruses (PMV) were one of the priority viral groups targeted for the surveillance. Here, we report discovery of novel PMV in wild rodent and shrews in Bangladesh. We collected oral and rectal swab samples from rodents (n= 1019) and house shrews (n=186) twice a year, in the dry and wet seasons, from three districts in Bangladesh from 2016 to 2018. To detect known and novel paramyxovirus, we tested swab samples using consensus PCR assay targeting RDRP genes of paramyxovirid specific generate primers. Overall, 2.1% (25/1205; 95% CI: 1.3-3.0) animals was positive against PMV.The prevalence of PMV was similar in rodents (2.06%; 21/1019) and shrews (2.15%; 4/186). We detected 04 novel strains of PMV from 25 samples of 06 species of rodents and house shrew. The PMV was more prevalent in wet than dry seasons.We identified landscape, sex, and health conditions significantly associated with PMV shedding in multivariable logistic regression model.Phylogenetic analysis revealed that three PMV strains identified in rodents are genetically related to Jeilongvirus. The discovery of one PMV strain genetically related to the novel zoonotic Langya virus in shrews warrants further investigation. However, the whole genome and molecular characterization are required to ascertain the virus pathogenicity and similarity with Langya or a novel strain of PMV. This study discovered that diverse strains of paramyxovirus, including those related to Langya virus, are present in shrews and rodents in Bangladesh. Future studies in Bangladesh should continue to characterize PMV viral diversity, and Langya virus should be included as possible etiologies for humans at high-risk human-animal interfaces that test negative for common pathogens.

INVESTIGATION OF RIFT VALLEY FEVER OUTBREAK ASSOCIATED WITH 'ABORTION STORMS' IN MBARARA DISTRICT, UGANDA 2023

Luke Nyakarahuka[1], Jackson Kyondo[1], Jimmy Baluku[1], Alex Tumusiime[1], Sophia Mulei[1], Shannon Whitmer[2], Joel Montgomery[2], Julius J. Lutwama[1], Stephen K. Balinandi[1], John D. Klena[2], Trevor R. Shoemaker[2]

[1]Uganda Virus Research Institute, Kampala, Uganda, [2]United States Centers for Disease Control and Prevention, Atlanta, GA, United States

Rift valley fever (RVF) is a zoonotic disease of public health and economic importance. Uganda has reported sporadic acute human cases since 2016 and identified convalescent livestock herds. In January 2023, acute disease with high fevers was reported in cattle among one dairy farm in Mbarara district as well as presenting with classical 'abortions storms' that is stereotypically characterized RVF diseases in larger outbreaks in the East-African rift valley. The Mbarara district rapid response team supported by the national rapid response team together with partners responded to these reports and blood samples were collected and taken to the Uganda Virus Research Institute (UVRI) for testing and confirmation. We conducted both human and veterinary investigations following a one health approach where 90 human samples, 42 cattle samples, 5 goat samples, and 4 milk samples from the affected farm were collected and tested by PCR, IgM, and IgG ELISA at the UVRI Viral hemorrhagic fever laboratory. Next Generation Sequencing (NGS) is being conducted and ongoing. To date (20th March 2023), 27.7% (25/90) human cases have been confirmed by PCR and IgM ELISA with 3 deaths, 23.8% (10/40) cattle tested positive by PCR and 69% (29/42) were positive by IgG ELISA whereas 2 sheep tested positive by IgG and 2 milk samples tested positive by PCR. 30 animals had reports of abortions in a space of two months within the one farm. 96% (24/25) of human cases reported contact with livestock, and 80% (20/24) are males with an average age of 37.7. Most human cases are alive (88%) and only 2 had hemorrhagic symptoms with the predominant symptoms being fever and general body weakness. This was the first active infection in cattle and milk samples that has been detected in Uganda associated with a cluster of acute human cases. Animal movement control measures were instituted to limit the spread and provided health education for high-risk groups such as abattoir workers and herdsmen. Recommendations for public health and animal preventive measures included immunization, vector control and health education in the affected communities to mitigate the effects of RVF.

5040

GENETIC DIVERSITY AND AMINO ACIDS VARIATIONS AT VACCINE TARGET SITES IN RABIES VIRUSES COLLECTED FROM DIFFERENT HOST SPECIES IN MAKUENI AND SIAYA COUNTIES, KENYA

Evalyne N. Wambugu[1], Kimita Gathii[2], Sarah Kituyi[3], Michael Washington[4], Clement Masakhwe[2], Lucy Mutunga[5], Gurdeep Jaswant[5], Thumbi Mwangi[5], Brian Schaefer[4], John Waitumbi[2]

[1]Walter Reed Project-Kenya, Kisumu, Kenya, [2]Walter Reed Project, Kisumu, Kenya, [3]Fogarty international center of the National institutes of health, Bethesda, MD, United States, [4]Uniformed Services University, Bethesda, MD, United States, [5]Institute of Tropical and Infectious Diseases, University of Nairobi, Kenya., Nairobi, Kenya

Rabies, a viral disease that causes lethal encephalitis is endemic in Kenya and is transmitted to humans mainly by domestic dogs. Rabies kills an estimated 2000 people annually, despite there being effective vaccines for dogs and humans. This study characterized the genetic diversity of RABV

obtained from brains of suspected rabid animals from Makueni county, Eastern region and Siaya county, Western Kenya and determined variances within the antigenic sites of RABV vaccines currently in use in Kenya. Brain biopsies (165) confirmed positive for rabies with rapid kits were collected between July 2021 and August 2022 from dogs, cats, cows, sheep and goats and re-screened for RABV by qPCR. Whole genome sequences (WGS) and individual nucleoprotein (N) and glycoprotein (G) genes were used for phylogeny. The amino acid variances in the N and G genes antigenic sites were compared to three RABV vaccine sequences: Pitman-Moore L503 (PM), Challenge Virus Standard (CVS) and the Pasteur vaccine (PV) strains. Of the 165 brain samples, 156 were positive by qPCR and 141 (74 from Makueni and 67 from Siaya) produced useable sequences. Phylogenetic lineages drawn from WGS, individual N and G genes showed two geographical distinct lineages: The Eastern Kenya sequences overwhelmingly (n=69) clustered with the Africa 1b lineage, with only 3 in Africa 1a. In contrast, the Western Kenya sequences (n=64) clustered with Africa 1a with only 3 in Africa 1b. The nearest common ancestor of the Africa 1a traced to Sudan, while the Africa 1b traced to Tanzania. The percent amino acid homologies of the N gene to the RABV vaccines were at least 97.6% for PV, 97.8% for CVS and 98.5% for PM. The homology with the G gene were at least 93.0% for PV, 93.3% for CVS and 92.2% for PM. Our data confirm geographical isolation of RABV in Eastern and Western Kenya. The data suggests limited migration, probably through wild carnivore movement or translocation of domestic dogs by humans. The observed amino acid variances RABV vaccines antigenic sites would predict good vaccine efficacy, indicating that the RABV endemicity in Kenya is due limited programmatic vaccine coverage.

A GUT COMMENSAL PROTOZOAN REMOTELY TUNES PULMONARY DISEASE SEVERITY

Kyle Burrows[1], Louis Ngai[1], Pailin Chiaranunt[1], Jacqueline Watt[2], Eric Cao[1], Sui Ling[1], Jun Liu[2], Arthur Mortha[1]

[1]Department of Immunology, University of Toronto, Toronto, ON, Canada, [2]Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada

The microbiome plays a crucial role in regulating the immune system. The bacterial composition of the microbiome, in particular, is known to alter eosinophil responses to various stimuli with certain bacterial profiles having been associated with increased susceptibility to the development of allergies and asthma. However, the precise role of the other microbial kingdoms within the microbiome, such as viruses, fungi, and protozoa, in modulating immune responses and susceptibility to disease is not yet fully understood. Commensal protozoa are an integral component of the vertebrate microbiota, yet they are vastly understudied compared to their pathogenic counterparts. While colonization with commensal protozoa is known to alter the local immune response in the intestine and aid in protection against enteric bacterial pathogens, it is unclear whether these organisms can also influence extra-intestinal immunity. Here, we show that the gut-dwelling commensal protozoan Tritrichomonas musculis (T. mu) can remotely shape the immune landscape in the lungs following colonization. Despite not directly affecting the health of the host, the presence of T. mu in the gut causes accumulation of eosinophils in the lungs and is dependent on the inter-organ migration of intestinal derived inflammatory group 2 innate lymphoid cells (iILC2). This sustained eosinophilia in the lungs also requires interaction between iILC2s, T cells, and B cells, which form a tripartite immune network that provides a specific niche for lung eosinophils. This network exacerbates allergic airway inflammation induced by house dust mite exposure while also limiting early bacterial dissemination following infection with Mycobacterium tuberculosis in mice colonized with T. mu. Collectively, this data indicates that commensal protozoa can tune the severity of multiple pulmonary diseases by triggering a lung immune network that enhances local eosinophilia which can have beneficial or detrimental effects on host fitness under different stimuli.

HYPOXIA PROMOTES CYTOLYTIC ACTIVITY OF CD8 T CELLS AND PATHOGENESIS IN CUTANEOUS LEISHMANIASIS

Erin Al. Fowler[1], Camila Amorim[2], Emily Ds. Hales[1], Aditi Varkey[1], Mariam Salem[1], Gang Xin[1], Patrick L. Collins[1], Fernanda O. Novais[1]

[1]Department of Microbial Infection & Immunity, Wexner Medical Center, The Ohio State University, Columbus, OH, United States, [2]Department of Pathobiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA, United States

Leishmaniasis is a diseasecaused by protozoan parasites of the genus Leishmania and the mostcommon form of the disease is cutaneous leishmaniasis (CL). A fundamentalquestion in CL is what regulates the development of severe disease, informationthat is critical to develop therapies to ameliorate pathology. In a series ofstudies, we demonstrated CD8 T cell-dependent cytotoxicity as the main inducerof immunopathology in CL. This result was unexpected since IFN-γ production byCD8 T cells plays a protective role by promoting pathogen elimination. Toresolve this paradox, we studied the CD8 T cells in different anatomic sitesand found that the effector function of CD8 T cells in CL depends on theirlocation: while CD8 T cells are cytotoxic (GzmB+) and produce little IFN-γ inthe skin lesions, CD8 T cells in the draining lymph nodes (dLN) have theopposite profile. Importantly, GzmB- CD8 T cells from dLN quickly upregulateGzmB after injection into CL lesions. By transcriptional profiling, we foundthat CD8 T cells in lesions but not dLN have a hypoxic signature. In vivo, weobserved that leishmaniasis lesions are hypoxic using the Oxyphor G4 oxygenprobe and pimonidazole staining. In vitro, we found that induction of hypoxiawas sufficient to convert GzmB- into GzmB+ CD8 T cells, and significantlydecreased CD8 T cells production of IFN-γ. Together these data stronglyimplicate hypoxia as the key factor driving CD8 T cells to become pathogenic inthe skin lesion. In vivo, mice with CD8 T cell deficient in HIF-1α also produced significantly less GzmB in the skinlesions compared to wildtype counterparts. We will also utilize a mouse linewhich has Cre stabilized in low oxygen to specifically delete HIF in the lesionto further analyze how HIF impacts CD8 T cell function in vivo. Together, ourresults suggest that the hypoxic signaling through the transcription factor HIFin CL lesions is the necessary factor that converts protective CD8 T cells intopathogenic cytotoxic T cells in the skin lesion.

CD30L EXPRESSION ON CD4+T CELLS IS REQUIRED FOR THE DEVELOPMENT OF ALLERGEN- AND HELMINTH-DRIVEN TYPE 2 INFLAMMATION IN THE LUNG

Camila de Almeida Lopes[1], Dominic Golec[2], Daniel Barber[2], Thomas Nutman[2], **Pedro Gazzinelli-Guimaraes**[2]

[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]National Institutes of Health, Bethesda, MD, United States

Type 2 immune responses are associated with helminth infections but also drive allergic disorders. Transcriptomic analyses of house dust-mite (HDM) driven pulmonary type-2 inflammation revealed a marked upregulation in genes associated with the Th2 activation pathways (e.g.IL-4, IL-5, IL-9, IL-13, and IL-33), but also other important inflammatory mediators including TNFSF8 also known as CD30L. Additionally, single cell RNA sequencing on CD45+-sorted lungs cells showed marked expression of CD30L on lymphoid cells, but most noticeably on allergen-activated CD4+ T cells. To explore the role played by CD30L in Type 2 associated pulmonary inflammation, we used two experimental mouse models, including HDM-intranasal sensitization and Ascaris infection in the lungs. Flow cytometry analysis revealed that the effector memory Th2 cells, defined by TCRb+CD4+CD44+CD154+IL-13+ from both HDM-allergic and Ascaris-infected lungs showed a marked over-expression of CD30L, when compared with naive cells. Interestingly, repeated infection with Ascaris parasites increased even further the frequency of CD30L+ Th2 effector cells in comparison with primary infection. We next examined the role of CD30L in the CD4+ T cell differentiation in vitro. Naïve cells from CD30L

KO mice or from naïve WT mice following CD30L blockade during in vitro differentiation into Th2 cells demonstrated a significant impairment of Th2 cell differentiation (fewer IL-4 producing Th2 cells). Finally, to further examine the functional role of CD30L during the development of a pulmonary type-2 inflammation, our data demonstrated that CD30L KO mice following sensitization to HDM failed to induce an allergen-specific memory Th2 cell response in the lungs when compared with WT mice, based on the marked reduction in the frequency of allergen-specific IL-13 producing memory CD4 T cells. This in turn led to diminished HDM-specific IgG1 and IgE levels, as well as a reduction of eosinophils in the lung tissue. Taken together our preliminary findings suggests that CD30L expression on Th2 cells is required for the development of type-2 inflammatory immune responses in the lung tissue.

HUMAN FILARIAL INFECTION DRIVES A DISTINCT SIGNATURE OF CD8+T CELL POPULATIONS AT HOMEOSTASIS AND IN RESPONSE TO CYTOMEGALOVIRUS (CMV) IN FILARIAL/CMV COINFECTIONS

Camila Queiroz Glauss, Thomas B. Nutman
National Institutes of Health, Bethesda, MD, United States

Characterization of the T cell responses in chronic filarial infections has focused largely on CD4+ subsets, with little information of CD8+ T cells. Because CD8+ T cells are central to viral-specific effector responses in most viral infections and because many occur in the context of coincident filarial infections, we sought to understand the nature of CD8+ populations and subpopulations in filarial/viral coinfections. We sought to characterize the heterogeneity and function of CD8+ T cells in filarial/cytomegalovirus (CMV) co-infected subjects through the use of multiparameter (26 color) flow cytometry to profile CD8+ subsets from PBMCs collected from 11 filarial-infected subjects (Fil+) and 6 filarial-uninfected controls (Fil-) at homeostasis and in response to cytomegalovirus (CMV) antigen (CD8 and CD4 megapools consisting of 345 peptides). We used a self-organizing map tool (FlowSOM) to profile CD8+ subsets driven by the filarial infection per se and by CMV. Based on the multidimensional profiling and clustering algorithms using data from PBMCs from all subjects at homeostasis (baseline), the Fil+ group had marked expansion of CD8+CD95+CD107a+PD-1+IFN-g+and CD8+CD45RA+CD107a+GranzymeB+IFN-g+ populations that reflect severe exhaustion and being pro-apoptotic. When stimulated with CMV antigen, the CD8+ T cells from Fil+ subjects expanded a population of CD8+GranzymeB+CD57+ cells compared to Fil- subjects ($p<0.03$) but failed to induce additional IFN-g and CD107a, both being important for viral control. Additionally, CMV antigen exposure induced a marked increase in the frequency of a memory CD3+CD8+ subset (CD8+CD45RA+CD161 +CD57+GranzymeB+Perforin+IL17+) whose function remains unknown. Our data suggest that filarial infection is associated with CD8+ T cell exhaustion and apoptosis; further when stimulated with viral antigen these CD8 subpopulations fail to produce the important cytokines necessary for viral control. These findings are likely important to understand the nature of bystander suppression of viral specific responses induced by chronic filarial infections.

5045

IL-11 REGULATES MUCOSAL RESPONSES IN ACUTE PULMONARY HELMINTH INFECTION

Pablo Bara-Garcia[1], Oyebola Oyesola[1], Fabricio Oliveira[2], Jonah Kupritz[1], Thomas B. Nutman[1], Pedro E. Gazzinelli-Guimaraes[1]
[1]Laboratory of Parasitic Diseases, NIAID, National Institutes of Health, Bethesda, MD, United States, [2]Laboratory of Immunology and Genomics of Parasites, Department of Parasitology, ICB, UFMG, Belo Horizonte, Brazil

Larval migration of helminth parasites through the lung drives an early neutrophil-associated inflammation before the establishment of an eosinophil-dominated type-2 immune response. Members of the IL-6 cytokine family, including IL-11, have been described to play a role in acute inflammatory responses. In a mouse model, we observed significantly elevated IL-11 levels in the lung tissue of mice following Ascaris spp. infection (2,196 pg/mL vs 968 pg/mL, $p<0.001$) at 8 dpi compared to naive mice. Flow cytometry and confocal imaging demonstrated that lung CD140a+ fibroblasts and EpCAM+ epithelial cells were major sources of IL-11 in the lungs of Ascaris-infected mice. Anti-IL-11 blocking antibodies during Ascaris infection markedly impaired the influx of neutrophils to the lung, whereas administration of rIL-11 not only induced high levels of G-CSF and CXCL1 but also increased neutrophil influx. By using Ascaris-infected IL-11Ra1 deficient mice, we observed a marked reduction in lung neutrophil influx (20.3 x 105cells vs 51.2 x 105cells, $p=0.030$) and a decrease of neutrophil-associated mediators (e.g., CXCL-1 and G-CSF) in the absence of IL-11 signaling when compared with WT Ascaris-infected animals. To elucidate whether IL-11 production by lung epithelial cells is elicited directly or indirectly, bronchial epithelial cell line (HBEC3-KT) grown in a monolayer on an extracellular gel matrix was shown to produce markedly increased (55% above baseline) amounts of IL-11 following exposure to Ascaris larvae. Moreover, HBEC3-KT cells stimulated in vitro with different recombinant cytokines, including IL-33, IL-1b, IL-1a, and TGF-β, revealed that TGF-β induces high levels of IL-11 in a dose dependent manner. Similar induction of IL-11 was observed in mouse fibroblast cell line (MM14. Lu) stimulated with TGF-β. Further pulmonary Ascaris larval migration drove a marked increase of TGF-β levels in vivo (1476.23 pg/mL vs 986.87 pg/mL, $p<0.001$). Taken together, our data suggests that IL-11 produced in the lung mucosa regulates a neutrophil-dominated inflammation in response to epithelial damage and TGF-β during acute lung helminth infection.

5046

RAPID INDUCTION OF CLINICAL TOLERANCE IN A PLACEBO-CONTROLLED CLINICAL TRIAL INVESTIGATING REPEATED CONTROLLED EXPOSURE TO SCHISTOSOMA MANSONI

Jan Pieter R. Koopman, Jacqueline J. Janse, Emma L. Houlder, Olivia A.C. Lamers, Geert V.T. Roozen, Angela van Diepen, Jeroen C. Sijtsma, Stan T. Hilt, Eileen van der Stoep, Inge M. van Amerongen-Westra, Eric A.T. Brienen, Linda J. Wammes, Lisette van Lieshout, Govert J. van Dam, Paul L.A.M. Corstjens, Maria Yazdanbakhsh, Ron H. Hokke, Meta Roestenberg
Leiden University Medical Center, Leiden, Netherlands

Epidemiological data from endemic settings suggests that (partial) immunity to schistosomiasis develops over time, and is likely enhanced by repeated infections and treatments leading to enhanced or prolonged antigen exposure. Moreover, animal studies have demonstrated that protection can be achieved after repeated immunisation with irradiated cercariae. In this study, we aimed to investigate the protective efficacy and safety of consecutive exposure-treatment cycles with Schistosoma mansoni (Sm) in healthy, schistosome-naïve participants using the single-sex controlled human Sm infection model. We enrolled 24 participants who were randomised (1:1) to either three (reinfection) or one (infection control) exposures to 20 male cercariae. The infection control group received two mock exposures first. Treatment with praziquantel (or placebo for infection controls) was given 8 weeks after the first and second (mock) exposure. All participants were treated with praziquantel 12 weeks after the third exposure. Throughout the study, adverse events were collected as well as serum to measure circulating anodic antigen (CAA) secreted by juvenile and adult worms to determine infection status. All but one participant completed follow-up. The percentage of participants with detectable infection after the final exposure (CAA ≥ 1.0 pg/mL) in the reinfection group was 82% (9/11) and 92% (11/12) in the infection control group. In the reinfection group, more related adverse events were reported after the first infection (45%) as compared to the second (27%) and third infection (28%). Severe acute schistosomiasis (AS) was observed in both groups after the first infection (2 out of 12 in reinfection group and 2 out of 12 in infection control group), but no AS was reported after the subsequent infections. In conclusion, repeated Sm infection led to clinical tolerance, but did not result in (sterile) protection. Further investigation into the underlying immune response will result in better understanding of immunity to schistosomes.

5047

COMPREHENSIVE ANTIBODY PROFILING IN SCHISTOSOMIASIS REVEALS IMMUNOLOGICAL SIGNATURES OF ACTIVE INFECTION

Anushka Saha[1], Trirupa Chakraborty[2], Sukwan Handali[3], William E. Secor[3], Lucia Alves de Oliveira Fraga[4], Jessica Fairley[5], Jishnu Das[2], **Aniruddh Sarkar**[1]

[1]Georgia Institute of Technology, Atlanta, GA, United States, [2]University of Pittsburgh, Pittsburgh, PA, United States, [3]Center for Disease Control and Protection, Atlanta, GA, United States, [4]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil, [5]Emory University, Atlanta, GA, United States

Lack of accurate yet accessible diagnostics for neglected tropical diseases such as schistosomiasis is a critical bottleneck in their elimination. Antibody (Ab)-based tests, currently used for serological screening for schistosomiasis cannot distinguish past from current infection. We have developed a multiplexed 'Ab-omics' platform for deep biophysical characterization (both Fab & Fc ends) of a broad set of antigen-specific Abs including not only their isotype and subclass but also glycosylation, Fc receptor and complement binding. Machine-learning applied to this high-dimensional data can reveal unique Ab signatures predictive of disease state and outcome. Here, we apply the Ab-omics pipeline to Schistosoma mansoni infection. Sera from patients (n=88, from Minas Gerais, Brazil), previously screened for parasite eggs using the Kato-Katz technique, were characterized with the Ab-omics workflow using multiple S. mansoni antigens (SEA, SM25, MEG, CD63, Calumenin) and other helminth and non-helminth antigens. Antigen-coated barcoded beads were incubated with serum and probed with various fluorescently-labeled isotype and subclass probes, tetramerized Fc receptors and lectins. This revealed that SEA-specific IgG titers could not discriminate between individuals who were egg+ and those who were egg-. However, higher SEA and CD63-specific IgG4, Calumenin-specific Ab FcγR2A and SM25-specific Ab FcγR3B binding and antigen-specific Ab sialylation were found in egg+ individuals compared to egg- individuals. With a total of 324 measured features (18 Ab Fc characteristics x 18 antigens) from each patient, application of a new interpretable machine-learning approach (Essential Regression) revealed a complex interplay of proinflammatory (FcγR2A, FcγR3B) and anti-inflammatory (sialylation) Ab features and functions. Machine-learning (LASSO) based feature selection was able to identify a unique set of biomarkers to differentiate egg+ from egg- individuals (AuROC~0.9). Our findings suggest that a purely Ab-based biomarker can achieve accurate diagnosis of current versus past schistosome infection in endemic areas.

5048

MODELING TO SUPPORT DECISIONS ABOUT THE GEOGRAPHIC AND DEMOGRAPHIC EXTENSION OF SEASONAL MALARIA CHEMOPREVENTION IN BENIN

Jeanne Lemant[1], Clara Champagne[1], Cyriaque Affoukou[2], Julien Aïssan[2], Rock Aikpon[2], William Houndjo[2], Sakariahou Kpanou[2], Didier Adjakidje[3], Emilie Pothin[1]

[1]Swiss Tropical and Public Heath Institute, Allschwil, Switzerland, [2]National Malaria Control Program, Ministry of Health, Cotonou, Benin, [3]Clinton Health Access Initiative, Boston, MA, United States

Seasonal malaria chemoprevention (SMC) has been implemented in Benin since 2019 and targeted more than 400 000 children under 5 in the northern departments of Alibori and Atacora in 2021. The Benin National Malaria Control Program (NMCP) recently considered an extension of SMC, either demographically - children aged 5 to 10 in the same departments would also receive SMC, or geographically to children under 5 in new departments eligible according to WHO criteria. As neither extension had been tested before, the NMCP turned to modeling to estimate their impact. The model OpenMalaria was calibrated to represent the history of malaria interventions and transmission risk in Benin, as well as the age structure of the population. The future interventions which were already planned (mass net distribution campaigns, SMC in children under 5 in Alibori and Atacora, pilot projects of intermittent preventive treatment in infants) were simulated, together with the two extensions of SMC. The model predicted that the demographic extension of SMC could avert on average 4.6 severe cases per 1000 targeted children between 2024 and 2026, while the geographic extension could on average avert between 13 and 14.3 severe cases per 1000 children under 5, depending on the department. To be less cost-effective than the demographic extension, the geographic extension should thus be three times more expensive, when costs from the 2021 campaign indicate it would cost only 40% more. Numbers of severe cases averted per targeted child were similar between operational zones of departments considered for the geographic extension, probably due to similar transmission risks. These findings led to recommend targeting in priority highly populated zones, as SMC in the three most populated zones could avert as many severe cases as in the six other zones. Modeling allowed not only to choose the geographic over the demographic extension, but also to quantify their comparative impact. Modeling can be used to answer questions from decision-makers when they are closely associated to the process, from the refinement of the modeling question to the choice of epidemiological indicators.

5049

USING CAUSAL INFERENCE METHODS TO ACCURATELY ESTIMATE THE EFFECT OF INSECTICIDE TREATED NET USE ON THE RISK OF MALARIA INFECTIONS

Noel Patson[1], Lauren Cohee[2], Peter Ntenda[1], Terrie Taylor[3], Don Mathanga[1], Clarissa Valim[4], Eric Tchetgen Tchetgen[5]

[1]Malaria Alert Center, Kamuzu University of Health Sciences, Blantyre, Malawi, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Department of Osteopathic Medical Specialties, College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, [4]Department of Global Health, Boston University School of Public Health, Boston, MA, United States, [5]Department of Statistics and Data Science, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States

Although randomized trials concluded that insecticide treated nets (ITNs) use prevent malaria infections, some observational studies have found no effect or even an increased risk of malaria with ITN use. These conflicting results may be explained by time-varying confounding e.g. perceived malaria risk. Briefly, as transmission increases, subjects tend to increase their ITN use, hence incorrectly suggesting that ITN use is positively associated with the risk of infection in the next time point. When time-dependent confounders are affected by prior exposure, standard methods yield biased results. Marginal structural models (MSM) have been widely used to accurately estimate treatment effect in the presence of time-dependent confounders, but not in ITN use. We estimated the effect of ITN use on the risk of clinical and subclinical malaria infection using MSM with inverse probability of treatment weights (IPTW) and compared results with a regular longitudinal model based on generalized estimating equation (GEE). We analyzed data from a cohort conducted in Malawi where 962 participants (median age=13 years) were enrolled from 198 households and followed for one year (median 11.4 months) in monthly scheduled and unscheduled sick visits. ITN use and perceived malaria risk were collected at every 1-month interval. A total of 938 incident subclinical and clinical malaria infections were detected using qPCR. IPWTs were generated at each time based on logistic regression including history of previous ITN use and other variables associated with malaria exposure. Then, longitudinal GEE MSM with IPTW were fitted for subclinical and any malaria infection outcomes, apart from the regular GEE model. For any malaria infection, GEE MSM with IPTW yielded a non-significant stronger ITN protective effect (OR=0.82; 95%CI=0.63-1.09; P=0.17) compared to the standard GEE analysis (OR regular GEE =0.92; 95% CI: 0.76, 1.11; p=0.37) that underestimated the ITN effect. The MSM with IPTW showed that ITN is mainly effectively protective against subclinical (OR=0.71; 95% CI= 0.52-0.98; P=0.04). Therefore, MSM provides reliable estimates for evaluating ITN impact.

MATHEMATICAL MODELLING TO SUPPORT STRATEGIC MALARIA PLANNING IN MOZAMBIQUE

Tatiana Alonso Amor[1], **Sophie Diarra**[1], James Colborn[2], Bradley Didier[2], Baltazar Candrinho[3], Emilie Pothin[1], Branwen Owen[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Clinton Health Access Initiative, Boston, MA, United States, [3]Ministry of Health Mozambique, Maputo, Mozambique

In setting the strategic plan for the period 2023 to 2030, the National Malaria Control Programme in Mozambique incorporated mathematical modelling to estimate the impact of four sub-national intervention plans. A ranking of geographic targets for seasonal malaria chemoprevention (SMC), perennial malaria chemoprevention (PMC), indoor residual spraying (IRS) and RTS,S vaccine from the 2020 stratification provided scenarios to be modelled. These were called "Business as Usual" (BaU) (insecticide treated nets, IRS), "Core" (BaU plus SMC and PMC, "Core Plus" (Core with SMC, PMC and the RTS,S vaccine) and "Ideal" (Core plus with more widespread SMC, PMC and the RTS,S vaccine), all with case management for simple and severe malaria. Using the OpenMalaria model, calibrated using historical data and transmission risk in Mozambique, the scenarios were simulated to assess impact on malaria. Modelled outputs included malaria prevalence, incidence, clinical cases and mortality. Each scenario was costed and cost-effectiveness analysis was used to assess what an optimal plan would entail, maximizing the number of cases averted in the under 5's and in the whole population. Comparing Plasmodium falciparum prevalence in 2030 vs in 2022 at the national level, the reduction in prevalence is 17% for the "Core" package, 19% for the "Core Plus" package and 20% for the "Ideal" package. When taking into consideration the cost of interventions, there exists an optimal plan that averts more cases than the "Ideal" package within the same budget. SMC and PMC appeared to be the most cost-effective interventions, with IRS and RTS,S only optimizing averted malaria cases with very large increments in the budget. Mathematical modelling provides a useful tool to support decision-making, specifically allowing for sub-national stratification. National strategic plans can be developed to optimize the number of malaria cases averted given a fixed budget envelope, and the potential long-term impact can be calculated.

CAUSES OF UNDER-FIVE DEATH USING A PROBABILISTIC MODEL (INTERVA5) IN QUELIMANE DISTRICT, CENTRAL MOZAMBIQUE

Charfudin Nicos Sacoor[1], Ariel Nhacolo[1], Alberto Chauque[1], Orvalho Augusto[1], Helio Amaro[1], Tonecas Armando[1], Daniel Massandudzi[1], Elisio Xerinda[1], Esperanca Sevene[1], Solveig Argeseanu[2], Jonathan Muir[2], Inacio Mandomando[1], Quique Bassat[3]

[1]Manhica Health and Research Centre, Manhica-Maputo, Mozambique, [2]Emory University, Department of Global Health, Atlanta, GA, United States, [3]Barcelona Institute for Global Health (ISGlobal), Hospital Clinic-Universitat de Barcelona, Barcelona, Spain

Community-based information on causes of stillbirths and under-five mortality is limited in many sub-Saharan countries. This is the case in Mozambique, where child mortality continues to be high despite a wide implementation and coverage of public health interventions with demonstrated impact. To understand why mortality levels remain high, we examine the underlying causes of death among stillbirths and children under the age of five years in Quelimane district, Central Mozambique. We aimed to include all stillbirths and under-5 deaths that occurred 12 months prior to the baseline census conducted from January to August 2022 in Quelimane district (population= 349,842). The main cause of death were computed using a computer algorithm InterVA-5. Only one cause of death was assigned for each case. The cause was chosen taking in consideration those with highest likelihood.Verbal autopsies were perform on 280 (79.1%) of a total 354 under-5 deaths identified through baseline census. The mean time between the date of death and verbal autopsy collection was 8.3 (SD, 5.36) months. Over half of the deaths (54.6.%) occurred at a health facility. Birth asphyxia was the most common cause of death among stillbirths and neonates (under 28 days of life), at 57.7% and 40.8% of deaths respectively, and it was more frequent among males. Diarrheic disease was the main cause of death among infants (1-11 months) at 46.0%. For older children aged 1- 4-years, malaria was the main cause of death among females (36.4%) and diarrheic disease was the most common cause in males (30.0%). Congenital malformations played an important role in childhood deaths up to the first year (4.3%). This study provided useful population-based insights on the causes of stillbirths and under-5 death and showed that most deaths occurred at health facilities and were related to preventable causes. Urgent strategic public health action targeting the health sector is needed to reduce facility deaths, including a redoubled attention to antenatal care, especially maximizing and improving the public health strategies currently available in order to save lives.

5052

INVESTIGATING THE ROLE OF HUMAN MOVEMENT ON DISEASES TRANSMISSION DYNAMIC IN KENYA, A TOOL FOR OUTBREAK PREPAREDNESS

Donal Bisanzio[1], Francis Mutuku[2], Said L. Malumbo[3], Jael S. Amugungo[3], Charles M. Ng'ang'a[3], Paul S. Mutuku[3], Desiree LaBeaud[4]

[1]RTI International, Washington, DC, United States, [2]Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya, [3]Vector Borne Disease Control Unit, Msambweni County Referral Hospital, Msambweni, Kenya, [4]Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA, United States

The spread of infectious diseases is influenced by human movement and its heterogeneity. Urban areas in high-income countries have been extensively studied in relation to human movement and infectious diseases, but there is a lack of research focusing on low-income countries. This study aims to describe the movement of people in two Kenyan urban settings and its impact on infectious diseases. From November to December 2021, we enrolled 200 participants representing the population of Ukunda and Kisumu, two urban settings in Kenya. We collected data on participant movement routines for two weeks through a semi-structured questionnaire. Each location listed by participants was geolocated. Spatial and network analysis were used to describe the movement patterns of participants. Using the results of the statistical analysis merged with data from Google Building, we built two synthetic populations of the study sites. The synthetic populations were used to build an individual-based model simulating a flu-like disease to identify individuals and locations with an important role in disease spread. We identified 702 locations across both sites with a median number of 4 people sharing a location in their routine (interquartile range [IQR]: 2-14 people). The median number of visited locations per person was 5 locations (IRQ: 4-6 locations). The most visited locations outside of individuals' homes were shops and markets, accounting for 42.6% of all listed locations. The distribution of visited locations among participants showed strong heterogeneity following a power-law distribution. The characteristics of movement routines recorded in the two sites were similar. The analysis of model results identified transmission hot-spot locations in the two cities and the fraction of the population which had an important role in disease spread. The results of our study demonstrate the feasibility of merging population surveys and freely available data to identify possible transmission hot-spots in low-income urban settings. The study method could be used to guide response interventions to mitigate and improve preparedness to handle disease outbreaks.

5053

IMPORTANCE OF COUNTRY PREPAREDNESS IN HANDLING HEALTH EMERGENCY, THE 2023 EBOLA OUTBREAK IN UGANDA

Donal Bisanzio[1], Sharone Backers[2], Richard Reithinger[1]

[1]RTI International, Washington, DC, United States, [2]RTI International, Kampala, Uganda

In September 2022, an Ebola outbreak caused by the Sudan ebolavirus occurred in Uganda. The outbreak was declared resolved in January 2023 with a toll of 142 confirmed cases, 55 of whom later died. As no vaccine is available for the Sudan ebolavirus, Uganda response was based on a range of non-pharmaceutical interventions (NPIs), including case isolation, tracing of case contacts, and population lockdowns to reduce the spread of the virus. The aim of the analyses was to evaluate the impact of NPIs on the Sudan ebolavirus outbreak by simulating scenarios with different response effort. We built a spatially-explicit synthetic population of Uganda which included heterogeneity of human contact and movement. This synthetic population was then used to perform an individual-based model (IBM) to represent the spread of Sudan ebolavirus in Uganda from September 2022 onwards. A baseline model was created to reproduce the epidemic curve of the outbreak, including the adopted NPIs and the timing of their implementation. To assess the effectiveness of the outbreak response, the baseline model was compared to a scenario simulating the NPI response with a 5 months delay, and one with a less-controlled outbreak. The IBM results showed that scenarios with a late intervention response and with an out-of-control outbreak would have resulted in an Ebola outbreak like the one reported by countries affected by the West Africa in 2014-2016. The late response scenario projected an outbreak with 778 (95% confidence interval [CI]: 665-901) cases and 303 deaths (95% CI: 259-351), 5.5 times higher than the reported outbreak. The outbreak simulated using the less-controlled scenario resolved with 1,818 (95% CI: 811-4,774) cases and 709 deaths (95% CI: 316-1862), 12.8 times higher than the reported outbreak. Our results showed how Uganda's rapid response to the Ebola outbreak was able to drastically reduce the toll of the 2022 Sudan ebolavirus outbreak. Our study highlights the significance of preparedness to manage infectious disease outbreaks, as a crucial factor in mitigating the risk of a significant public health emergency

5054

THE GLOBALMIX PROJECT: COMPREHENSIVELY PROFILING SOCIAL CONTACT PATTERNS IN RESOURCE POOR COUNTRIES

Moses Chapa Kiti[1], Obianuju G. Aguolu[2], Noureen Ahmed[2], Charfudin Sacoor[3], Azucena Bardaji[4], Ivalda Macicame[5], Herberth Maldonado[6], Rajan Srinivasan[7], Venkata Raghava Mohan[7], Momin Kazi[8], Alessia Melegaro[9], Fauzia Malik[2], Saad B. Omer[2], Ben Lopman[1]

[1]Emory University, Atlanta, GA, United States, [2]Yale University, New Haven, CT, United States, [3]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, [4]ISGlobal, Barcelona, Spain, [5]Instituto Nacional de Saúde, Maputo, Mozambique, [6]Universidad del Valle de Guatemala, Guatemala City, Guatemala, [7]Christian Medical College, Vellore, India, [8]Aga Khan University, Karachi, India, [9]Bocconi University, Milan, Italy

Social mixing data are the cornerstone of understanding the transmission and modeling the control of pathogens such as SARS-CoV-2, RSV, influenza, and measles that spread via close contact. However, there is a dearth of data on social contact patterns particularly from low-and-middle-income countries. Comparability is hampered with different study protocols, definition of a contact, tool design and data collection procedures and many modelers rely on European contact data projected onto low-and-middle-income country populations. To address this gap, we aimed to quantify social contact patterns in a total of 8 rural and urban sites of Mozambique, Guatemala, India, and Pakistan through The GlobalMix Study. For each country, 1,260 participants reported, in a paper diary, individuals with whom they had contact over two days, and characteristics of those contacts. In addition, members of 126 households carried wearable proximity sensors over 7 continuous days and concurrently kept a diary of all contacts over two of those days. Each sensor autonomously detects dyadic face-to-face (<6 feet separation) interactions between household members. We will present contact rates and matrices stratified by standardized definitions of age, sex, relationship, occupation, location, and duration of contacts for each site and country. We will quantify household and overall temporal network characteristics such as degree, number and duration of contacts, node loyalty and cosine similarity, and further compare these to contemporaneous diary data. We will present output from Mozambique and showcase the utility of our data. We report 8.8 (95% CI 8.4-9.2) and 6.3 (6-6.6) mean contacts per person per day in rural and urban areas, respectively. The highest median contacts were reported by 15-19-year-olds, and the highest assortativity by school children aged 10-14 years. These patterns are consistent with other studies in resource poor settings. An overarching value of The GlobalMix Study is to make the tools, methods, and data available to the scientific community for use in mathematical models of infectious disease transmission and control.

5055

TRANSMISSIBILITY OF LEISHMANIA DONOVANI FROM HUMAN TO SAND FLIES IN AN AREA ENDEMIC FOR VISCERAL LEISHMANIASIS IN INDIA

Om Prakash Singh[1], Puja Tiwary[1], Anurag Kumar Kushwaha[1], Shakti Kumar Singh[1], Dhiraj Kumar Singh[1], Rahul Chaube[1], Abhishek Kuamr Singh[1], Tulika Rai[1], Edgar Rowton[2], Jaya Chakravarty[1], David Sacks[3], Shyam Sundar[1]

[1]Banaras Hindu University, Varanasi, India, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]National Institute of Allergy and Infectious Diseases, National Institute of Health, Bethesda, MD, United States

On the Indian sub-continent, visceral leishmaniasis (VL) is a fatal form of leishmaniasis caused by the protozoan parasite Leishmania donovani, and transmitted by the bites of the vector sand fly, Phlebotomus argentipes. To achieve and sustain elimination of VL, the transmission potential of L. donovani exposed individuals from across the infection spectrum needs to be urgently addressed. We conducted direct xenodiagnosis on each of the active VL patients (n=77) and Post Kala-azar Dermal Leishmaniasis (PKDL) patients (n=26), before and after successful treatment, asymptomatic individuals (n=183) and HIV-VL patients (n=14). During xenodiagnosis, 30 - 35 female flies were exposed for 30 min on each site on the subject's forearm and lower leg, or the forearm only. Blood-engorged female flies were held in an environmental cabinet at 28°C and 85% humidity. At 60 -72 hours post- blood meal, flies were dissected and evaluated for L.donovani infection by microscopy as well as by quantitative polymerase chain reaction (qPCR). A subject was considered positive for infectivity to sand flies if promastigotes were observed in one or more individual flies by microscopic exam, or in one or more of the pools of flies by qPCR analysis. We found that 54.6% (42/77) and 77.9%(60/77) of active VL patients transmitted parasites to at least one fly or pools by microscopy and qPCR, respectively. Transmission of infection correlated with severity of VL disease. None of the drug cured VL patients were found xenodiagnosis positive by microscopy at 30 days post-treatment, although 7.7 %(6/77) were still positive by qPCR. Both nodular and macular PKDL patients were infectious to sand flies, with enhanced transmission when the flies were fed on nodular lesions. 92.8%(13/14) HIV-VL co-infected patients transmitted infection to flies. Importantly, none of the 184 asymptomatic subjects were infectious to sand flies. In conclusion, these findings confirm that active VL, PKDL and HIV-VL patients transmit L. donovani to the vector, but that early diagnosis and treatment will effectively remove these individuals as infection reservoirs.

MOLECULAR IDENTIFICATION OF LEISHMANIA IN STAINED SLIDES FROM PATIENTS WITH CUTANEOUS LEISHMANIASIS IN SANTARÉM, PARÁ, BRAZIL

Lucia Maria Almeida Braz[1], Vanessa N. Kehdy[1], Nara Karyne D. Feitosa[2], Rose Grace B. Marques[3], José Angelo L. Lindoso[4], Expedito José A. Luna[5]

[1]FMUSP - IMT, São Paulo, Brazil, [2]Nucleo Técnico de Vigilancia em Saúde, Santarém, Pará, Brazil, [3]Núcleo Técnico de Vigilância em Saúde, Santarém, Pará, Brazil, [4]Instituto de Infectologia Emilio Ribas, São Paulo, Brazil, [5]FMUSP, São Paulo, Brazil

Tegumentary leishmaniasis (TL) is an infectious disease caused by the protozoan Leishmania. The correct identification of the species of Leishmania is important epidemiologically and to adequate therapy. For the diagnosis of the disease, parasitological tests are used but they cannot identify species. The use of PCR (polymerase chain reaction) can be performed from different biological samples, such as stained smears stained on slides and previously examined by microscopy. As a target for PCR, the ITS-1 (internal transcribe space-1) region of the ribosomal RNA has an adequate number of polymorphisms for species-level distinction, in addition to conserved regions of diagnostic importance. Our objective was to identify Leishmania species from lesion smears from patients with suspected TL, residing in Santarém, Pará, Brazil. For the procedure, 40 lesion smears stained by Giemsa on microscopy slides, from 40 patients with suspected TL, were analyzed by microscopy (1000X) in the laboratory of the Núcleo Técnico de Vigilância em Saúde(NVTS)/Pará. These smears were subjected to DNA extraction using Qiamp DNA Mini (Qiagen) and the DNA was subjected to PCR, according to the amplification conditions used by GODOY et al, 2020. The amplified (320pb) product was submited to the Sanger sequencing. Our results showed that from 40 slides examined microscopically, 30 were positive and 10 were negative. Of the 10 negatives on microscopy, 100% (10/10) were negative on PCR. Of the 30 positives on microscopy, 83% (25/30) were positive on PCR-ITS-1. 18 samples from 25 submitted to sequencing showed the following results after alignment: 4 Leishmania (Viannia) lainsoni, 4 L. (Leishmania) amazonensis, 1 L. (V.) shawi, 2 L. (V.) guyanensis, 3 L.(V.) braziliensis, 1 L.(V.) naiffi ,1 L.(V.) panamensis and 2 L. panamensisi/guyanensis. Molecular investigation using ITS-1 as a target showed a specificity of 100% and a sensitivity of 83%.The sequencing of the ITS-1 intergenic region showed that there is a great diversity of Leishmania Viannia species in Santarém and L. (V.) braziliensis is not the most prevalent species in Santarém, Pará, as seen throughout Brazil.

5057

USEFULNESS OF ANTI A-GAL ANTIBODIES AS BIOMARKERS OF THERAPEUTIC RESPONSE IN CHAGAS DISEASE

Jaime Altcheh[1], Manuel Abal[2], Cintia V. Cruz, MD[3], Virginia Balouz[4], Maria E. Giorgi[5], María C. Marino[6], Rosa M. Muchnik de Lederkremer[6], Carlos Buscaglia[7]

Assessment of parasitological cure in Chagas Disease (CD) relies on achieving consistent negative results in parasitological and conventional serological tests. However, conventional serological reagents were optimized for diagnosis. These are based on mixtures of native or recombinant Trypanosoma cruzi antigens and display suboptimal performance as post-therapeutic biomarkers with low specificity and a long period required for negativization after treatment (known as seroconversion). Novel biomarkers are urgently needed. The F2/3 antigenic fraction of T. cruzi tripomastigotes, whose major epitope is the α-Gal glycan (Galp(α1-3) Galp(β1-4) GlcNAc), has been proposed as biomarker of early treatment response. However, its standardization remains challenging as large quantities of live infective parasites are required to produce it. We recently developed a synthetic αGal antigen. Here, we evaluated the use of antibodies anti αGal antigen as a biomarkers of treatment efficacy in a cohort of T. cruzi-infected children. Serological responses against αGal antigen were evaluated using an in-house enzymelinked immunosorbent assay (ELISA) and compared to conventional ELISA (TcELISA). We included 71 children (0-16 years old) with 479 samples in total. At baseline, αGal antibody was reactive in 38/71 patients (53.5%). After treatment, in children < 1 year (n=15) αGal antibodies became negative earlier than TcELISA (median of 8 months [range 1 to 98] and 33.5 mo [range 7 to 99], respectively). In children 1 to 7 years old (n=12) the seroconversion was also earlier than with TcELISA (median of 48 months [range 2 to 107] and 113 months [range 46 to 107], respectively). Finally, in patients older than 7 years (n=11) the median time of negativization with αGal was 62 months [range 26 to 149] whereas TcELISA did not became negative. This is the first study that evaluates the performance of αGal as biomarker of treatment response in CD. Our results suggest that the antibodies anti αGal would shorten follow-up periods following CD treatment. Just as important, αGal would facilitate the implementation of clinical trials with new drugs, an urgent need in CD.

5058

CUTANEOUS LEISHMANIASIS DISEASE AWARENESS IN HIGH ENDEMIC, RURAL SRI LANKA: NEED FOR IMPROVED HEALTH PROMOTION

Sonali Dinushika Gunasekara[1], Nuwan Darshana Wickramasinghe[1], Manjula Weerasinghe[1], Manoj Sanjeewa Fernando[2], Helen Philippa Price[3], Thilini Chanchala Agampodi[1], Suneth Buddhika Agampodi[4]

[1]Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Saliyapura, Sri Lanka, [2]Faculty of Applied Sciences, Rajarata University of Sri Lanka, Mihinthale, Sri Lanka, [3]Centre for Applied Entomology and Parasitology, School of Life Sciences, Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom, [4]International Vaccine Institute, Seoul, Korea, Republic of

Understanding community knowledge gaps in neglected tropical diseases is vital for planning context-specific prevention and control measures. Over 3000 cutaneous leishmaniasis (CL) cases are reported in Sri Lanka annually. We aimed to assess knowledge of CL among community in a disease-endemic region in Sri Lanka. We conducted a household survey in Anuradhapura district, Sri Lanka using a multi-stage cluster sampling method. The households' health-related decision-makers were the primary respondent. We used a semi-structured interviewer-administered questionnaire developed through a community engagement and involvement approach. Our sample included 1555 participants with a 98.4% response rate. Participants' mean age was 48.2 years (SD=13.8), and 1157 (74.4%) were females. Most had completed 11 years in school (n=634, 40.8%). Participants included housewives (n=637, 41.0%), farmers (n=301, 19.4%), self-employers (n=156, 10.0%) and others (n=461, 29.6%). Among participants, 1250 (80.4%) claimed they had heard of the disease (mostly the local name, 'sand fly or sand flea disease') while only 141 (11.3%) knew the term 'leishmaniasis'. Of those who had heard of the disease, 612 (49.0%) claimed they knew only the name. Among

the participants who knew more about the disease other than its name, 224 (35.1%) were aware that sand fly is the vector of leishmaniasis. The majority reported red (n=173, 27.2%), long-lasting (n=153, 24.0%), and pimples (n=378, 59.4%) as the main characteristics of early cutaneous leishmaniasis lesions. After excluding people with CL, 475 (77.4%) believed they are susceptible to leishmaniasis mainly due to having a family member or neighbor with leishmaniasis and the abundance of Maana in the surrounding area (an invasive grass belonging to the genus Glyceria). Notably, 518 (81.2%) believed leishmaniasis is curable, and 313 (49.1%) knew they should reach the district hospital for treatments. We identified community knowledge gaps related to the vector, clinical manifestations and treatment facilities for leishmaniasis, and public awareness programs should be tailored to address these identified gaps.

5059

A COST-EFFECTIVE LAMP-PCR FOR SCREENING AND MONITORING CHAGAS DISEASE

Sneider Alexander Gutierrez Guarnizo[1], Anshule Takyar[1], Siena Defazio[1], Monica Mugnier[1], Robert Gilman[1], Juan Ramirez[2], Monica Pajuelo[3]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Universidad del Rosario, Bogotá, Colombia, [3]Universidad Peruana Cayetano Heredia, Lima, Peru

The standard treatment for Chagas disease is efficient during the acute phase but only 1% of patients are treated because of poor early diagnosis. Most currently available PCR-based diagnostic methods are expensive, not portable, and do not consider the genomic variability of the parasite. A more specific, sensitive, and cost-effective tool is urgently needed to improve the early screening for Chagas disease in low-income endemic regions. A loop mediated isothermal amplification (LAMP-PCR) was designed for targeting a highly conserved region in the HSP70 gene of Trypanosoma cruzi. Backward, forward and loop primers were manually designed across a region of 236 bp. The optimal melting temperature and delta G values were estimated in the OligoAnalyzer tool (IDT). Our LAMP-PCR protocol amplified T. cruzi DNA from discreet typing units (DTUs) I, II, IV, V, and VI. The reaction did not amplify DNA from T. rangeli or Leishmania (L. amazonensis, L. braziliensis) used as controls. The proposed method was able to detect about 28 fg of parasite DNA extracted from infected blood samples at 1X106 epimastigotes/mL, equivalent to less than one parasite. Parasite DNA could be detected in different types of samples including blood coat, anticoagulated blood, and buffy coat. This method is fast, temp stable, and cheap. This portable method can facilitate the screening and monitoring of patients in endemic regions for Chagas disease. Further efforts will be focused on simplifying the DNA extraction protocol, evaluating clinical samples, and scaling the method in endemic regions.

5060

A SET OF DIAGNOSTIC TESTS USEFUL FOR THE DETECTION AND IDENTIFICATION OF LEISHMNANIA PARASITES CAUSING CUTANEOUS LEISHMANIASIS

Yusr Saadi[1], Ahmed Chakroun[1], Hamed Chouaieb[2], Hejer Souguir[1], Insaf Bel Haj Ali[1], Alia Yaacoub[2], Moncef Ben Said[2], Akila Fathallah-Mili[2], Ikram Guizani[1]

[1]Molecular Epidemiology & Experimental Pathology, Institut Pasteur de Tunis, Tunis, Tunisia, [2]Parasitology department, Farhat Hached University Hospital, Sousse, Tunisia

The new WHO roadmap for NTDs 2021-2030 identified diagnostics among top priorities to achieve the 2030 targets for Leishmaniases control. Simple, rapid and accurate diagnostics are essential to control CL. Leishmania (L) species identification is essential for diagnosis, patient's management and an adequate therapeutic strategy. Diagnosis tools applied for the identification of L. parasites depends on laboratory equipment and facilities. The aim of this study was to develop a set of innovative and specific molecular tools for L species detection and identification adapted for well as well as poorly equipped laboratories. Using comparative genomic analyses of L. genomes we selected species specific, distinctive targets and designed a range of PCR primer pairs that we assessed for taxa-specific DNA amplification of L species encountered in MENA region. Four primer pairs were retained. Three of them, showing L. species-specific amplification, were investigated to develop a PCR multiplex-lateral flow chromatography (LF) on a customized microfluidics for DNA-DNA hybridization. This test requires basic equipment such as a thermocycler. Readout for detection and identification is made in 3' on the LF after a 2h PCR. Another pair was designed for generic amplification of a L. DNA fragment containing species-specific SNPs adequate for PCR High Resolution melting analysis (PCR-HRM) as an alternative test in well equipped centers with the advantage of detection and identification made by the software at the endpoint (1h30'). Both approaches reduce time to result delivery and obviate the need for agarose gel electrophoresis. Tested on reference L.strains, the tests were shown to consistently identify the studied L. species and to have an analytical sensitivity of detection of 0.01ng & 0.002ng for the PCR-LF and the PCR-HRM, respectively. Tested on cutaneous samples collected from the Parasitology department-Farhat Hached UH Tunisia, the tests showed promising sensitivity & specificity. The study delivers simple and specific tools for accurate detection & identification of L. parasites in clinical samples that could be used as diagnosis tests

THE PATHWAY TO SUSTAINABLE ELIMINATION OF HUMAN AFRICAN TRYPANOSOMIASIS IN DEMOCRATIC REPUBLIC OF CONGO

Crispin Lumbala wa Mbuyi[1], Pascal Lutumba[2], Jean-Pierre Van geertruyden[1]

[1]University of Antwerp, Wilrijk, Belgium, [2]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the

Gambiense HAT (gHAT) has been targeted for elimination as public health problem (PHP) by 2020 and now for elimination of transmission (EoT) by 2030. The Democratic Republic of the Congo (DRC), the most affected country; is inexorably moving towards gHAT elimination countrywide. As the trend of the disease may vary from one region to another, we aim to analyze the disease current results and trend toward gHAT elimination as well as the quality and coverage of gHAT control activities using data archived in the WHO Atlas of HAT from 2000 to 2016 at country, provincial and health district (HD) levels. We found that the prevalence of gHAT in DRC was substantial decreased. However, provinces, like Maindombe and Kwilu remained most prevalent compared to others like Nord Ubangi and Sud Ubangi. HAT screening coverage, population attendance rate to active screening, the proportion of patients who received treatment, and the therapeutic efficacy rate have been identified as factors associated with disease trend. Around 16.0% of the 257 endemic HDs, that reported at least one case of HAT between 2000 to 2016, had not yet reached the target of HAT elimination as PHP according to Franco et al (2020) in 2016. Although the number of people actively screened annually remained almost stable, active screening was poorly implemented according to the recommended algorithm. Nearly two-thirds of endemic HDs were not covered by a health facility (HF) implementing the full range of HAT activities and approximately 40% of endemic health areas were not covered by a HF capable of screening for HAT. Active screening as implemented and the low coverage of passive screening may hide some cases that could be a source of resurgence in the future and do not appear to be sufficient to ensure surveillance in the post-elimination period and provide sufficient confidence in sustainability towards an EoT. And indeed, one fact that appears to support this conclusion is a relative increasing number of cases in the country between 2020 and 2021 from 395 to 425. There is a need to improve coverage and implementation of active and passive screening strategies and monitor to confirm current achievement in DRC.

DETECTION OF SALMONELLA TYPHI BACTERIOPHAGES IN SURFACE WATERS AS A SCALABLE APPROACH TO ENVIRONMENTAL SURVEILLANCE

Kesia da Silva[1], Sneha Shrestha[2], Jivan Shakya[3], Alexander T. Yu[1], Nishan Katuwal[2], Rajeev Shrestha[2], Mudita Shakya[2], Sabin B. Shahia[2], Shiva R. Naga[2], Christopher LeBoa[4], Kristen Aiemjoy[5], Isaac I. Bogoch[6], Senjuti Saha[7], Dipesh Tamrakar[2], Jason R. Andrews[1]

[1]Department of Medicine, Division of Infectious Diseases and Geographic Medicine, Stanford University, Stanford, CA, United States, [2]Center for Infectious Diseases, Dhulikhel Hospital Kathmandu University Hospital, Dhulikhel, Nepal, [3]Institute for Research in Science and Technology, Kirtipul, Nepal, [4]University of California Berkeley, Department of Environmental Health Sciences, Berkeley, CA, United States, [5]University of California Davis, School of Medicine, Department of Public Health Sciences, Davis, CA, United States, [6]Department of Medicine, Division of Infectious Diseases, University of Toronto, Toronto, ON, Canada, [7]Child Health Research Foundation, Dhaka, Bangladesh

Environmental surveillance, using detection of Salmonella Typhi DNA, has emerged as a potentially useful tool to identify typhoid-endemic settings; however, it is relatively costly and requires molecular diagnostic capacity. We sought to determine whether S. Typhi bacteriophages are abundant in water sources in a typhoid-endemic setting, using low-cost assays. We collected drinking and surface water samples from urban, peri-urban and rural areas in 4 regions of Nepal. We performed a double agar overlay with S. Typhi to assess the presence of bacteriophages. We isolated and tested phages against multiple strains to assess their host range. We performed whole genome sequencing of isolated phages, and generated phylogenies using conserved genes. S. Typhi-specific bacteriophages were detected in 54.9% (198/361) of river water samples and 6.3% (1/16) drinking water samples from the Kathmandu Valley and Kavrepalanchok. Water samples collected within or downstream of population-dense areas were more likely to be positive (72.6%, 193/266) than those collected upstream from population centers (5.3%, 5/95) (p=0.005). In urban Biratnagar and rural Dolakha, where typhoid incidence is low, only 6.7% (1/15, Biratnagar) and 0% (0/16, Dolakha) samples contained phages. All S. Typhi phages were unable to infect other Salmonella and non-Salmonella strains, nor a Vi-knockout S. Typhi strain. Representative strains from S. Typhi lineages were variably susceptible to the isolated phages. Phylogenetic analysis showed that S. Typhi phages belonged to two different viral families (Autographiviridae and Siphoviridae) and clustered in three distinct groups. S. Typhi bacteriophages were highly abundant in surface waters of typhoid-endemic communities but rarely detected in low typhoid burden communities. Bacteriophages recovered were specific for S. Typhi and required Vi polysaccharide for infection. Screening small volumes of water with simple, low-cost plaque assays enables detection of S. Typhi phages and should be further evaluated as a scalable tool for typhoid environmental surveillance.

SEROINCIDENCE OF SALMONELLA ENTERICA SEROVARS TYPHI AND PARATYPHI IN CHILDREN IN KENYA

Aslam Khan[1], Izabela Rezende[1], Richelle Charles[2], Francis Mutuku[3], Bryson Ndenga[4], Zainab Jembe[5], Priscilla Maina[5], Philip Chebii[5], Charles Ronga[4], Laura Mwambingu[4], Victoria Okuta[4], Donal Bisanzio[6], Jason Andrews[1], Angelle D. LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Massachusetts General Hospital, Boston, MA, United States, [3]Technical University of Mombasa, Mombasa, Kenya, [4]Kenya Medical Research Institute (KEMRI), Kisumu, Kenya, [5]Vector Borne Disease Control Unit, Msambweni, Kenya, [6]RTI International, Washington, DC, United States

Salmonella enterica serovars Typhi and Paratyphi can cause variable disease which can range from asymptomatic carriage to significant illness and mortality globally. Diagnosis is often limited by access to microbiologic laboratories in low and middle income countries where there is high prevalence and risk of infection. Surveillance is therefore impacted with no great understanding of the population-level burden of infection. Here we applied a new serologic tool to measure population-level incidence from cross-sectional serosurveys using anti-IgG and IgA responses to a typhoidal pore-forming toxin (Hemolysin E). We tested serum from Kenyan children collected in 2017 in four different communities, two in western Kenya (Kisumu and Chulaimbo) and two in coastal Kenya (Ukunda and Msambweni). We found a substantial difference in typhoidal exposure in western and coastal Kenya, with an approximate 10-fold higher difference in the IgG response in the coastal communities, suggesting a higher burden of these pathogens in the region. We also explored for associated risks, specifically evaluating the role of the water source, population density, and wealth in those communities and found high seroincidence with non-piped water, higher population density, and lower wealth. These insights are of great importance as there is limited serological typhoid data available from Kenya and especially the coastal region. This information can shed more evidence for the importance of surveillance and vaccination implementation for the Kenyan community.

EFFICACY AND SAFETY OF A TYPHOID CONJUGATE VACCINE: FINAL ANALYSIS OF A FOUR-YEAR, PHASE 3 TRIAL IN MALAWIAN CHILDREN

Priyanka D. Patel[1], Yuanyuan Liang[2], James E. Meiring[1], **Nginache V. Nampota-Nkomba**[3], Theresa Misiri[1], Felistas Mwakiseghile[1], Leslie P. Jamka[4], J. Kathleen Tracy[4], Osward Nyirenda[3], Richard Wachepa[1], Robert S. Heyderman[5], Matthew B. Laurens[4], Melita A. Gordon[1], Kathleen M. Neuzil[4]

[1]Malawi- Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Blantyre Malaria Project, Blantyre, Malawi, [4]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [5]Division of Infection and Immunity, University College London, London, United Kingdom

A single dose of typhoid conjugate vaccine has been shown to be safe, immunogenic, and efficacious in preventing typhoid fever in Malawian children for 18 months post-vaccination. Here, we present long-term efficacy data after an extended surveillance period of 4-4.61 years post-vaccination in Malawi. We assessed the efficacy and safety of a typhoid Vi polysaccharide tetanus toxoid conjugate vaccine (Vi-TT) in a phase 3, double-blind, randomized controlled clinical trial in Blantyre, Malawi. Participants aged 9 months - 12 years were individually randomized in a 1:1 ratio to receive single dose Vi-TT or control meningococcal capsular group A conjugate vaccine (MenA). Vaccine efficacy was defined as the percentage reduction in the incidence rate ratio for blood-culture confirmed typhoid fever among Vi-TT compared to MenA recipients. We included 28,130 children in the intention-to-treat analysis (14,069 Vi-TT and 14,061 MenA). During passive surveillance, we screened 39,174 febrile study children, 10,777 met suspected typhoid eligibility criteria and 10,136 blood cultures were collected. Typhoid fever occurred in 24 Vi-TT participants and 110 controls, translating to an overall incidence of 39.7 (95% confidence interval (CI): 25.4-59) and 182.7 (95% CI 150.1-220.2) per 100,000 person-years of observation, respectively, and an overall vaccine efficacy of 78.3% (95% CI 66.3%-86.1%). When stratified by sequential one-year time intervals, vaccine efficacy was 83.4% (60.1%-94.3%) between year 0 and 1 after vaccination, 77.0% (42.9%-92.3%) between year 1 and 2, 77.0% (16.4%-95.8%) between year 2 and 3, 68.2% (27.2%-87.6%) between year 3 and 4, and 90.1% (30.5%-99.8%) between year 4 and 4.61. Vaccine efficacy was similar among three age groups (<2 years: 70.6%; 2-5 years: 79.6%; ≥5 years: 79.3%; p=0.85). There were 554 severe adverse events and 34 deaths; none of them were considered related to vaccination. In conclusion, a single dose of Vi-TT is safe, and provides high sustained vaccine efficacy over at least 4 years after administration in all age groups studied, including children who will receive the vaccine during routine immunization.

CROSS PROTECTION OF HETEROLOGOUS SHIGELLA FLEXNERI 2A AND S. SONNEI CHALLENGE IN HEALTHY ADULTS IN THEUNITED STATES

Kawsar R. Talaat[1], Chad K. Porter[2], Subhra Chakraborty[1], Bridgett Finley[1], Arthi Rameshkumar[1], Jessica L. Brubaker[1], Sandra D. Isidean[3], Courtney M. Swisher[1], Madison M. Billingsley[1], Brittany L. Feijoo[1], Katherine J. DeTizio[3], Kamal Dhanjani[1], Barbara DeNearing[1], Akamol E. Suvarnapunya[4], Nicole Maier[5], Patricia Njuguna[6], Calman MacLennan[7]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Naval Medical Research Command, Silver Spring, MD, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD, United States, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [5]PATH Center for Vaccine Innovation and Access, Washington, DC, United States, [6]PATH Center for Vaccine Innovation and Access, Seattle, WA, United States, [7]Bill and Melinda Gates Foundation, Seattle, WA, United States

Shigella is a major cause of diarrhea in low- and middle-income countries, as well as becoming increasingly antibiotic resistant. Efforts are underway to develop vaccines against Shigella; however, the diverse serotypes of disease-causing strains necessitate a multivalent vaccine. Understanding conserved epitopes and correlates of protection can aid in the design of broadly protective vaccines. This controlled human infection model (CHIM) study sought to assess cross-protection and markers of protection after challenge and heterologous rechallenge with different Shigella serotypes. Cohort 1 was challenged with S. sonnei, followed by a S. flexneri 2a challenge 3 to 4 months later. Cohort 2 was challenged with S. flexneri, followed by a S. sonnei challenge 4 months later. Naïve volunteers were included with each rechallenge to ensure acceptable attack rates. Stools were collected and tested for the challenge organism. Blood and stool samples were saved for immunologic assays. A total of 46 individuals were enrolled; 28 received S. sonnei, of which 19 were rechallenged with S. flexneri. Eighteen subjects received S. flexneri 2a; 10 were rechallenged with S. sonnei. In preliminary analyses, of the naïve volunteers who were challenged with S. sonnei, 18/28 (64%) met the consensus criteria for shigellosis or required early treatment. Of the volunteers challenged initially with S. flexneri 2a, 13/17 (77%) met shigellosis or early treatment criteria. Among volunteers initially challenged with S. sonnei, 4/19 (21%) met shigellosis or early treatment criteria following subsequent challenge with S. flexneri. In contrast, among volunteers initially challenged with S. flexneri, 8/10 (80%) met shigellosis or early treatment criteria following S. sonnei challenge. Stool culture data support the clinical findings. Immunologic analyses are ongoing. In conclusion, prior S. sonnei exposure provides significant protection against S. flexneri 2a. Prior S. flexneri 2a infection provides no clear protection against subsequent S. sonnei infection. These data raise intriguing questions about conserved epitopes and immunological memory.

5066

DEVELOPMENT OF A SHIGELLA MULTIVALENT BIOCONJUGATE VACCINE: A PHASE I/II RANDOMIZED, CONTROLLED AND AGE DESCENDING STUDY INCLUDING DOSE FINDING IN KENYAN INFANTS

Chinaza Ezirim[1], Cristina Alaimo[1], Mainga Hamaluba[2], Josphat Kosgei[3], Jane Adetifa[2], Patricia Martin[1]

[1]LimmaTech Biologics, Schlieren, Switzerland, [2]KEMRI-CGMRC, Kilifi, Kenya, [3]KEMRI-USAMRD-K, Kericho, Kenya

Shigella is among the most common causes of severe diarrhea and dysentery worldwide, especially among young children from lower resourced countries and travelers. Although several oral Shigella vaccines have been clinically evaluated, risk of reactogenicity and potential reversion back to a pathogenic phenotype have proven challenging. Thus, a new type of vaccine to prevent shigellosis is key. The O-antigen serotype-specific immune response detected in association with convalescence from shigellosis has encouraged development of a new generation of glycoconjugates as an alternative vaccine strategy against Shigella. A Shigella flexneri 2a bioconjugate has shown, in a controlled human infection model, protection from the most severe form of the disease after challenge with S. flexneri 2a strain 2457T. In addition, immune responses post vaccination were associated with a lower disease severity score. The potential of bioconjugation to develop a high fidelity and cost-effective multivalent Shigella vaccine targeting the most common serotypes contributing to global morbidity and mortality has been exploited. The tetravalent Shigella4V bioconjugate, including O-antigens from S. flexneri 2a, 3a, 6 and sonnei, has been evaluated for safety and immunogenicity in the target population of 9 months old infants. The trial was conducted in Kenya starting with a step 1, age descending and dose-escalating cohort, followed by a step 2 dose finding cohort where the target population received a 3 dose schedule of the bioconjugate delivered with and without alum adjuvant. The doses used were 4, 12, 24 and 48 µg which each represents the total polysaccharide across the four Shigella O-antigens. The last patient last visit occurred in Q4 2022 and immunogenicity and safety data (from the target population) from the interim analysis (IA) was made available in Q3 2022, the remaining data will be available in Q4 2023. The IA data has shown good immunogenicity 1 month post 2nd vaccination across all treatment groups and serotypes along with well distributed and mostly mild safety events. Following the positive IA results, we have progressed towards the next steps.

5067

HUMAN MILK OLIGOSACCHARIDES AND CAMPYLOBACTER JEJUNI INFECTION RISK IN NICARAGUAN CHILDREN

Rebecca J. Rubinstein[1], Roberto Herrera[2], Christian Toval-Ruíz[2], Nadja Vielot[1], Lester Gutiérrez[2], Yaoska Reyes[1], Fredman González[2], Patricia Blandón[2], Natalie Bowman[1], Lars Bode[3], Filemón Bucardo[1], Sylvia Becker-Dreps[1], Samuel Vilchez[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Universidad Nacional Autónoma de Nicaragua-León, León, Nicaragua, [3]University of California San Diego, San Diego, CA, United States

Campylobacter jejuni infection causes acute gastroenteritis and is associated with malnutrition, stunting, and cognitive delays. C. jejuni uses α-1,2 fucosylated and sialylated oligosaccharides on the intestinal epithelia as binding factors to infect the gut. Human milk oligosaccharides (HMOs) in breastmilk may protect against C. jejuni infection by acting as decoy receptors for C. jejuni and by shaping the gut microbiome. We examined HMOs and C. jejuni infection risk in an observational cohort of non-exclusively breastfed infants in Nicaragua. HMO composition at 2 months (range 1.1-4.8) was measured with fluorescent high-and-ultra-high-pressure liquid chromatography. Children were surveilled weekly for diarrhea, and C. jejuni in stool was detected using qPCR of the 16S rRNA and cadF genes followed by Sanger sequencing. We mapped cumulative risk of C. jejuni infection over 36-months by tertiles of concentrations of the α-1,2 fucosylated HMOs 2'-fucosyllactose (2'FL) and lacto-N-fucopentaose-I (LNFP-I), and the siallylated HMOs 3'-siallylactose (3'SL) and 6'SL. We also assessed the 12 and 36-mo relative hazards (HR) of C. jejuni infection for each HMO stratum, adjusting for total weeks of any breastfeeding at the time of HMO collection. Analyses were stratified by child secretor and Lewis B phenotypes which determine oligosaccharide expression in the gut epithelium. Of 419 mother-child pairs with breastmilk analyzed, 49 (12%) had at least one C. jejuni infection. Surprisingly, in the first 12 months of life, Lewis B and secretor children consuming the top tertile of 3'SL (HR=2.09, 95% CI 1.02, 4.30), had twice the risk of C. jejuni infection compared to children consuming the bottom tertile of both HMOs. This difference attenuated slightly between 12-36 months. As expected, Lewis B children consuming milk in the top tertile for 2'FL (HR=0.5, 95% CI 0.24, 1.03) and LNFP-I (HR=0.49, 95% CI 0.25, 0.99) had half the risk of infection of children consuming milk in the lowest tertile for both HMOs. Our findings support evidence that the α-1,2 fucosylated HMOs 2'FL and LNFP-I may protect against C. jejuni infection in breastfeeding children.

5068

PREDICTING SEROCONVERSION FAILURE AFTER ORAL POLIO VACCINATION IN CHILDREN IN LOW- AND MIDDLE-INCOME COUNTRIES

Sharia M. Ahmed[1], Ben J. Brintz[1], Patricia B. Pavlinac[2], James A. Platts-Mills[3], Daniel T. Leung[1]

[1]University of Utah, Salt Lake City, UT, United States, [2]University of Washington, Seattle, WA, United States, [3]University of Virginia, Charlottesville, VA, United States

While there has been tremendous progress in the eradication of poliovirus, close to 50 countries are either experiencing or are at high risk of re-emergence of polio. The majority of polio infections are in low and middle income countries (LMICs), where oral vaccine efficacy is lower than in higher-income countries, associated with poorer vaccine immunogenicity. Our goal was to develop a clinical prediction rule to identify children likely to fail to seroconvert after polio vaccination. We used clinical and demographic data from the Etiology, Risk Factors, and Interactions of Enteric Infections and Malnutrition and the Consequences for Child Health and Development (MAL-ED) study to build predictive models to identify children who fail to seroconvert following oral polio vaccination (OPV) in eight countries. Failure to seroconvert was defined as a log2 titer <3 for polio-virus serum neutralizing antibody titers measured using WHO-standardized microneutralization assays collected at 7 and 15 months of age. We screened variables using random forests, and assessed predictive performance with random forest regression and logistic regression using cross-validation. Of the 1294 children analyzed who received at least three doses of OPV, 15.1% and 11.5% had failed to seroconvert at 7 and 15 months, respectively. Top predictors were well-aligned with known risk factors of seroconversion failure, including breastfeeding practices, indicators of household crowding, maternal education, and acute diarrhea and respiratory symptoms. Our ability to predict seroconversion failure was poor for serotype 1, serotype 3, and polio of any serotype (AUC)=0.58 (95% CI: 0.55, 0.62) for a model including the top five predictive variables. For serotype 2, we achieved an AUC=0.77 (95% CI: 0.73, 0.81) with five predictive variables. Our findings indicate that use of prediction rules may help identify children at risk of failure to seroconvert after vaccination, which could help target polio eradication efforts. We also demonstrate that predictive ability differs by serotype, and how risk factors may not be the best predictors of vaccine immunogenicity.

5069

ASSESSING THE CONTRIBUTION OF NUCLEOTIDE VARIATIONS IN THE MAYARO VIRUS GENOME TO ITS ADAPTIVE LANDSCAPE IN AEDES AEGYPTI AND ANOPHELES ALBOPICTUS MOSQUITOES

Rafael Kroon Campos[1], Sasha R. Azar[2], Tina Nguyen[1], Judy Ly[3], Ruimei Yun[1], Bilal Khan[1], Shannan L. Rossi[4], Scott C. Weaver[5]

[1]Department of Microbiology and Immunology, University of Texas Medial Branch at Galveston, Galveston, TX, United States, [2]Department of Surgery, Houston Methodist Research Institute, Houston, TX, United States, [3]Department of Pathology, University of Texas Medial Branch at Galveston, Galveston, TX, United States, [4]Department of Pathology and the Institute for Human Infections and Immunity, University of Texas Medial Branch at Galveston, Galveston, TX, United States, [5]Department of Microbiology and Immunology and the Institute for Human Infections and Immunity, University of Texas Medial Branch at Galveston, Galveston, TX, United States

Mayaro virus (MAYV) is an arbovirus of the Alphavirus genus and the etiologic agent of Mayaro fever (MAYF). MAYV is maintained in forests by an enzootic cycle, and no urban outbreaks have been confirmed to date. With the expansion of the Aedes (Stegomyia) mosquito distribution, and MAYV continuous circulation, we hypothesized that infection of these mosquitoes by MAYV could result in adaptive mutations that favor transmission. To investigate mutations that could arise in MAYV infection of A. aegypti and A. albopictus from Salvador, Brazil, we fed these mosquitoes a blood meal containing 7 log10 PFU/ml of clonally derived MAYV strain CH (genotype D) which resulted in an 85% infection rate at 14 days post feeding. The salivary glands were dissected and organized into 3 pools of 15 glands each. The RNA was deep sequenced with Illumina (NextSeq 550), and analyzed for single nucleotide polymorphisms using LoFreq software. For A. aegypti and A. albopictus, respectively, we identified 128 and 30 minority variants that were not present in the parental virus. We selected mutations occurring in the genome of at least one MAYV strain on the Pubmed database for study, to reflect those that could be occurring in nature, and applied a Z-score to rank them. We have cloned and rescued four of these naturally occurring mutations in the Mayaro CH background and tested their fitness for infection and transmission using competition assays in mosquitoes and dissected the salivary gland for analysis. Only one of these viruses, with a mutation in nsP3, had increased fitness as assessed using salivary gland samples. For future studies of nucleotide variations in the context of MAYV genotype L, we also described and characterized a novel MAYV clone, strain BeH505465. These results suggest that minority variants that provide a modest fitness advantage for MAYV transmission by Aedes mosquitoes could arise after a single infection round and may contribute to the risk of urban outbreaks. This work underscores the critical importance of surveillance efforts to quickly identify urban emergence and the urgent need to develop effective vaccines and treatments against MAYF.

USING BARCODED WEST NILE VIRUS TO QUANTIFY THE IMPACT OF TISSUE-ASSOCIATED BOTTLENECKS ON VIRUS POPULATIONS IN ENZOOTIC AND BRIDGE VECTORS OF WEST NILE VIRUS

Emily Anne Fitzmeyer, Emily N. Gallichotte, Kyra Pyron, Marylee Kapuscinski, Gregory D. Ebel

Colorado State University, Fort Collins, CO, United States

Each step during arthropod infection constitutes a physiological barrier to virus transmission. These barriers impose stochastic reductions on arbovirus populations, frequently termed bottlenecks. In vectors of West Nile virus (WNV), the main bottlenecks associated with infection, dissemination, and transmission occur during infection of and escape from the midgut and salivary glands. The severity of these bottlenecks varies by tissue and potentially mosquito species. Arboviruses such as WNV are maintained in nature by multiple mosquito species with varying levels of vector competence (VC, efficiency of pathogen transmission). Importantly, the extent to which population bottlenecks and VC are linked is poorly understood. Additionally, quantitative analyses of mosquito bottlenecks on virus population dynamics are limited. To address these knowledge gaps, we used molecularly barcoded WNV (bcWNV) to quantitatively measure tissue-associated population bottlenecks in Culex tarsalis, Culex quinquefasciatus, and Aedes aegypti - three variably competent WNV vectors. In all species we observed reductions in bcWNV population richness and complexity upon escape from the midgut and entry of the salivary glands. In Aedes mosquitoes, barcode diversity in the midgut was significantly lower compared to Culex species. Importantly, population richness and complexity did not differ significantly between salivary glands and saliva from any species, indicating that bottleneck severity post-midgut infection does not differ between vectors of varying competence. Barcode frequency in the input population was positively correlated with successful transmission in Culex, however, high frequency in the bloodmeal did not guarantee transmission in any species. Cx. tarsalis, had the highest probability of transmitting rare barcodes when compared to lower competence vectors. This work provides insight into stochastic influences on virus population dynamics during mosquito infection in vectors of varying competence and suggests that vector competence may influence the successful transmission of rare virus variants in a population.

INTRA-HOST DIVERSITY IN VACCINATED COVID-19 PATIENTS INFECTED WITH DIFFERENT SARS-COV-2 VARIANTS

Beatriz de Carvalho Marques[1], Cecília Banho[1], Renan Souza[2], Nikos Vasilakis[3], **Lívia Sacchetto**[1], Maurício Nogueira[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]The University of Texas Medical Branch, Galveston, TX, United States

Virus Intra-Host Genetic Diversity (IHGD) can influence transmission and virulence by evading host immune response and disease severity, especially for SARS-CoV-2 variants. First, to evaluate the IHGD in unvaccinated (Uv, individuals infected with SARS-CoV-2, without any dose of vaccine) and vaccinated (V, individuals vaccinated with two doses of CoronaVac - Butantan/Sinovac) patients, we analyzed 120 COVID-19 samples from São José do Rio Preto and surrounding cities, obtained from April to July 2021. Total RNA was extracted, and the whole-genome sequencing was performed using Illumina CovidSeq. Using Pangolin COVID-19 Lineage Assigner Tool, these genomes were classified into Gamma lineage. The intra-host single nucleotide diversity analysis was carried out using LoFreq, and annotation and prediction of genetic effects was annotated using the SnpEff. The inference of selective pressures was performed using HyPhy to detect codons evolving on diversifying (DS) or purifying selection (PS). Our results evidenced that vaccination with CoronaVac favors negative selection at the intra-host level, in different genome regions, especially in nonstructural protein-coding genes, preventing further SARS-CoV-2 genetic diversity and reinforcing the importance of vaccination to reduce virus transmission. After this, we aim to analyze the influence of booster doses on IHGD of SARS-CoV-2 in COVID-19 patients infected with other variants. So far, total RNA and whole-genome sequencing have been carried out on 762 samples from patients with two or three doses of vaccine, obtained from October 2021 to December 2022. Genomes were classified in the VOCs Delta and Omicron, of which 475 correspond to patients who received two doses of vaccine, and 287 correspond to patients who received three doses. Our next steps are subdividing the samples based on vaccination status, vaccine type (inactivated virus, viral vector, and RNA technologies), and SARS-CoV-2 variant to compare intra-host diversity in different conditions and investigate possible immune-escape mutations among vaccinated individuals.

VIRAL SEQUENCE DATA FOR EPIDEMIOLOGICAL CHARACTERIZATION OF GLOBAL DENGUE VIRUS OUTBREAKS

Sindiso Nyathi, Izabella Mauricio Rezende, A. Desiree LaBeaud

Stanford University, Stanford, CA, United States

Dengue is a re-emerging arbovirus that poses a significant public health risk. Dengue virus exhibits complex disease dynamics driven by a range of factors including those acting at the evolutionary scale such as clade replacement, ecological scale such as climate change, and demographic scale such as urbanization. These factors influence the emergence and expansion of the virus, resulting in outbreaks in previously naïve areas. Despite the increase in frequency of dengue virus outbreaks in recent years, a detailed characterization of these outbreaks and identification of potential evolutionary, ecological and demographic drivers of dengue introduction and subsequent spread has not been conducted. In this analysis we use publicly available viral sequence data downloaded from online databases to characterize detected outbreaks of dengue virus, and determine the influence of evolutionary, ecological and demographic drivers on dengue outbreaks. Viral sequence data annotated with date and location information corresponding to the envelope gene portion of dengue 2 virus was downloaded from publicly available online databases. Maximum likelihood phylogenetic trees were inferred in RaxML from aligned sequences and used to define sequence clusters corresponding to dengue outbreaks. Outbreaks sequences were defined as genetically similar clusters of sequences collected within a date range from the same location. Birth-death skyline models in BEAST2 were used to infer key epidemiological parameters of each identified outbreak cluster, including time varying effective reproductive number and sampling proportion. Epidemiological parameters derived from phylodynamic models were used to compare global outbreaks of dengue 2 virus and show the potential influence of evolutionary, ecological and demographic drivers on dengue outbreaks. Our analysis utilizes a global sequence dataset to determine the factors influencing dengue virus outbreaks.

5073

THE IMPACT OF TEMPERATURE ON WEST NILE VIRUS MOSQUITO BOTTLENECKS AND ANTIVIRAL IMMUNITY

Emily Gallichotte, Emily Fitzmeyer, Gregory Ebel

Colorado State University, Fort Collins, CO, United States

West Nile virus is an arbovirus that is mainly transmitted by Culex mosquitoes. Within a mosquito, viruses encounter four physical barriers during systemic infection: midgut infection barrier, midgut escape barrier, salivary gland infection barrier, and salivary gland escape barrier. The strength of each of these barriers varies by virus, mosquito species, and other factors (e.g., microbiome, coinfection, etc.). Temperature is frequently the strongest abiotic factor impacting the efficiency of WNV transmission by Culex. However, the relationship between temperature and the strength of each bottleneck within the mosquito is poorly understood. Arboviruses exist in nature as genetically complex mutant swarms, with bottlenecks stochastically reducing the size and complexity of these virus populations. To mimic this genetic diversity, we utilized a barcoded West Nile virus (bcWNV) containing ~106 unique genetic markers that are approximately fitness neutral. We infected Cx. tarsalis with bcWNV and held them at 22°C, 26°C and 30°C to determine the role of temperature on the strength of population bottlenecks during arbovirus infection of mosquito vectors. We observed similar infection rates and viral loads in all mosquito tissues regardless of temperature. Using deep sequencing, we will determine the extent to which temperature impacts WNV population diversity and complexity. Additionally, increased temperature is known to alter many aspects of mosquito biology, but its impacts on mosquito antiviral immunity are currently unclear. We will thus characterize how temperature impacts mosquito antiviral responses to determine if altered temperatures change expression of innate immunity (focusing on the JAK-STAT, IMD, Toll, and RNAi pathways). Together, these results will shed light on the relationships between temperature, virus evolutionary dynamics and antiviral immunity.

GENOMIC SURVEILLANCE DURING THEFIRST-EVER HYPERENDEMIC TRANSMISSION OF ALL FOUR DENGUE VIRUS SEROTYPES IN NICARAGUA IN 2022 REVEALS NEW VIRAL INTRODUCTIONS POST-PANDEMIC

Gerald Vasquez[1], Cristhiam Cerpas[2], Hanny Moerira[1], Jose Soto[1], Mabel Hernandez[1], Jose Juarez[1], Josefina Coloma[3], Shannon Bennett[4], Eva Harris[3], Angel Balmaseda[2]

[1]Sustainable Science Institute, Managua, Nicaragua, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [4]California Academy of Sciences, San Francisco, CA, United States

Nicaragua, as with most Central and South American countries, has been severely impacted over the last decades by major epidemics of dengue. Since dengue virus (DENV) detection in 1985, co-circulation of serotypes has been limited to two or three, with one always predominating. However, for the first time in the country's epidemiological history, we detected the co-circulation of all four serotypes of DENV in Nicaragua in 2022. Here, we describe the molecular and epidemiological characteristics of the 2022 epidemic to better understand the evolutionary histories of DENV currently circulating. Our findings show an introduction of a new clade of DENV-1 into the country more closely related to viruses circulating in Ecuador in

2014 than to prior DENV-1 circulating in Nicaragua in 2016, although both fall within the American/African genotype V. DENV-2 sequences were all members of the same lineage that recently dominated in Nicaragua, in association with the 2016 and 2019 epidemics, falling within the American/Asian genotype II. DENV-3 viruses, last circulating in Nicaragua in 2014, fell within the same genotype III (Indian subcontinent) as before but formed a distinct group more closely related to Southeast Asian strains from as recent as 2019 as well as strains circulating in Florida and Cuba in 2022 than to prior Nicaraguan strains. The sequences of DENV-4, which very rarely causes clinical cases in Nicaragua, all fell within genotype IIB and descended from a widespread South American lineage with strong similarity to recent records from Mexico (2021) and Florida (2022). Our study reveals a shift in the epidemic dynamics in Nicaragua with a rise to co-dominance of DENV-1 and DENV-4 taking over where DENV-2 was formerly most common, and a strong influence of introduction and global exchange shaping the pattern of DENV circulation for three of the four serotypes. With a resurgence of travel following pandemic-related border closure and re-openings, DENV co-circulation of multiple serotypes across much broader regional scales could impact herd immunity and case severity rates and have other public health impacts yet to be determined.

[1]Redeemer's University, Ede, Nigeria, [2]Broad Institute of Harvard and MIT, Cambridge, MA, USA, MA, United States, [3]University of Maryland Medical Center,, Baltimore, MA, USA, MD, United States, [4]ISTH, Irrua, Nigeria, [5]Microsoft Premonition,, Redmond, Washington, USA, WA, United States, [6]FETHA, Abakaliki, Nigeria, [7]FMC, Owo, Nigeria, [8]NCDC, Abuja, Nigeria

Effective infectious disease surveillance is essential for clinical care and pandemic prevention, but few clinical tests are widely available. Additionally, the presence of one pathogen does not always mean the absence of others, and many infections have overlapping, nonspecific symptoms. Lack of diagnostics is challenging in low- and middle-income countries (LMICs), where the disease burden is the largest. As a result, misdiagnoses with common infections or a lack of diagnosis often occur. Metagenomics can identify species in samples, diagnose infections, and track outbreaks. However, metagenomics is typically used in highly resourced environments, with a need for information on its most valuable and practical application. We applied and evaluated metagenomic sequencing in three different contexts: population-level surveillance of cases suspected of Lassa Fever, investigation of three suspected outbreaks, and diagnosis of clinically challenging cases. We characterized viral infections in the plasma of 612 samples collected in Nigeria over four years (2017-2020) to assess the suitability of unbiased metagenomic sequencing for pathogen surveillance and detection. We made sequencing libraries using the Illumina Nextera platform and assigned taxa to reads via the Microsoft Premonition pipeline, followed by de novo assembly of viral genomes. Using this single workflow, we assembled the genomes of 13 viruses, including the first genomes of human blood-associated dicistrovirus and Coxsackievirus-B3 from Nigeria. We also identified the aetiology of two outbreaks – yellow fever virus and Monkeypox virus – and correctly failed to identify an infectious aetiology in a suspected outbreak that was ultimately determined to be caused by pesticide poisoning. We identified plausible etiologies in two of the eight clinically difficult cases. Therefore, a regional, Nigerian-driven metagenomics approach to public health problems can quickly and accurately identify different pathogens. Genomics infrastructure in LMICs provides an opportunity to use infectious disease genomics thoughtfully as we move beyond the SARS-COV2 pandemic.

ASSESSING RISK FACTORS FOR MALARIA AND SCHISTOSOMIASIS AMONG CHILDREN IN MISUNGWI, TANZANIA, AN AREA OF CO-ENDEMICITY: A MIXED METHODS STUDY

Claudia Duguay[1], Jacklin Mosha[2], Natacha Protopopoff[3], Franklin Mosha[4], Charles Thickstun[1], Eliud Lukole[2], Elizabeth Mallya[4], Tatu Aziz[2], Cindy Feng[5], Alphaxard Manjurano[2], Alison Krentel[1], Manisha A. Kulkarni[1]

[1]University of Ottawa, Ottawa, ON, Canada, [2]National Institute for Medical Research Tanzania, Mwanza Research Centre, Mwanza, Tanzania, United Republic of, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [5]Dalhousie University, Halifax, NS, Canada

Malaria and schistosomiasis are two major parasitic vector-borne diseases that are a particular threat to young children in rural areas of Sub-Saharan Africa. In the present study, we investigated factors that are associated with malaria, schistosomiasis, and co-infection among school-aged children, using an explanatory sequential mixed-methods approach. A cross-sectional study was conducted in January 2022 in Misungwi, Lake Victoria zone, Tanzania, that sampled 1,300 children aged 5 to 14 years old for malaria and schistosomiasis. Mixed-effect logistic regression models were used to assess the association between infection prevalence and seroprevalence, and environmental determinants that create favorable conditions for vectors and parasites and social determinants that relate to disease exposure. Community mapping combined with direct field observations were conducted in August 2022 in two selected villages from the cross-sectional study to understand specific water use behaviours and to identify potential malaria mosquito larval breeding sites and freshwater snail habitat. The prevalence of malaria, seroprevalence of schistosomiasis, and co-infection in this study were 40.4%, 94.3%, and 38.1%, respectively. Individual-level factors emerged as the primary determinants driving the association with disease infection, with age and sex (boys vs girls) being statistically and positively associated with malaria, schistosomiasis, and co-infection ($P<0.05$ for all). Community maps identified many unimproved water sources in both villages that were used by humans, cattle, or both. We found that children primarily fetched water, and that unprotected wells were dedicated for drinking water whereas ponds were dedicated for other domestic uses and cattle. Although not identified in the community maps, we found hand pumps in both villages that were not in use because of unpleasant taste and cost. This study improves our understanding of social and environmental factors that are associated with malaria, schistosomiasis, and co-infection which can inform potential entry points for integrated disease prevention and control.

ONE HEALTH APPROACH TO NIPAH VIRUS OUTBREAK INVESTIGATION AMIDST OF COVID-19 PANDEMIC IN BANGLADESH, 2021-2022

Ariful Islam[1], Shariful Islam[2], Shusmita Dutta Choudhury[2], Sarah Munro[1], Md Abu Sayeed[2], Md Mehedi Hasan[2], Md. Zulqarnine Ibne Noman Noman[2], Abdul Khaleque Md. Dawlat Khan[2], Nabila Nujhat Chowdhury[2], Sharmin Sultana[2], Ahmad Raihan Sharif[2], Mohammad Enayet Hossain[3], Maryska Kaczmarek[1], Md Ziaur Rahman[3], Tahmina Shirin[2], Jonathan H Epstein[1]

[1]EcoHealth Alliance, New York, NY, United States, [2]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh, [3]One Health laboratory,International center for diarrheal disease research (icddr,b), Dhaka, Bangladesh

Nipah virus (NiV) is an emerging bat-borne virus causing fatal encephalitis outbreaks. Until 2020, Bangladesh reported 319 NiV cases with >70% mortality. Amidst the COVID-19 pandemic, A multidisciplinary team investigated five suspected NiV spillover events in three districts of Bangladesh between 2021 and 2022 to identify the source, behavioral risk practices, and environmental exposures. We collected epidemiological, behavioral, and ecological data from outbreak communities and biological specimens of bats. We captured 60 Pteropus medius bats per outbreak event and environmental pool urine samples (N=314) from seven bat roosts within 10km radius of the outbreak's epicenter. The bat samples were tested for NiV by rRT-PCR and consensus PCR assay targeting rdrp genes of paramyxovirus (PMV) to detect known and novel PMV and to screen serum samples using multiplex Luminex assay for henipavirus panel. We detected two novel henipa-like paramyxoviruses in bats. The seroprevalence of NiV was 15.2% (34, CI: 10.74%-20.56%), and Hendra virus was 1.3% (3/224), Cedar 1.3% (3/224), Mojiang 0.9% (2/224) and Kumasi virus 1.3% (3/224). The behavioral investigation showed that all cases had a history of drinking contaminated raw date palm sap (RDPS) within 14 days prior to the onset of symptoms. In the outbreak communities, the participants have the habit of drinking RDPS 73.1% (CI: 67.04%-78.51%), eating bat bitten fruits 17.96% (CI: 13.36%-23.35%). Moreover, around 47% of the respondents had date palm trees in their household, among 74.78% were nursing. Serological and virological data showed diverse henipavirus circulating in bats. The high density of date palm trees and habits of drinking raw sap and eating half-eaten fruits in the outbreak communities. Drinking bat contaminated RDPS might be the source of NiV infection in humans. We recommend stringent one health surveillance and awareness campaigns in high-risk communities to reduce human-bat interactions and minimize spillover of the bat-borne virus to humans.

DELINEATING THEROLE OF RATS, CLIMATE AND ENVIRONMENT AS DRIVERS OF LEPTOSPIRA SPILLOVER TRANSMISSION USING ECO-EPIDEMIOLOGICAL GEOSTATISTICS IN AN URBAN BRAZILIAN INFORMAL SETTLEMENT

Max Eyre[1], Fábio N. Souza[2], Pablo R. Cuenca[3], Nivison Nery Jr.[2], Daiana de Oliveira[2], Jaqueline S. Cruz[2], Marbisa NR das Virgens[2], Juliet O. Santana[2], Mayara C. de Santana[2], Gielson A. Sacramento[2], Hussein Khalil[4], Kathryn P. Hacker[5], Elsio A. Wunder Jr[6], James E. Childs[6], Mitermayer G. Reis[7], Mike Begon[8], Peter J. Diggle[3], Albert I. Ko[6], Emanuele Giorgi[3], Federico Costa[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Institute of Collective Health, Federal University of Bahia, Salvador, Brazil, [3]Centre for Health Informatics, Computing, and Statistics, Lancaster University Medical School, Lancaster, United Kingdom, [4]Swedish University of Agricultural Sciences, Umea, Sweden, [5]University of Pennsylvania, Philadelphia, PA, United States, [6]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [7]Oswaldo Cruz Foundation, Brazilian Ministry of Health, Salvador, Brazil, [8]Department of Evolution, Ecology and Behaviour, University of Liverpool, Liverpool, United Kingdom

Rat-borne leptospirosis is an emerging zoonotic disease in marginalised urban settings globally. Spillover transmission is driven by complex interactions between humans, the rat reservoir, rainfall and the microenvironment, but has not been studied through a One Health approach. We conducted a longitudinal eco-epidemiological study in a high-risk community in Brazil, by following a cohort of 2,115 residents during a three-year period (2014-2018) and ascertaining serological evidence for leptospiral infection during biannual serosurveys. A concurrent rat ecology study collected information on the fine-scale spatial distribution of tracking plate measurements of 'rattiness', our proxy for rat abundance and exposure of interest, during each of the six follow-up periods. We developed and applied a novel eco-epidemiological spatiotemporal geostatistical framework to jointly model rattiness and human infection risk. The overall cohort infection rate was 11.9 (95%CI, 11.0, 12.9) infections per 1,000 person-months. We found that residents who were male, with low literacy skills, walked barefoot, had experienced heavy rainfall or household flooding, or who lived in households at low elevations, close to an open sewer or with a soil backyard were at increased risk of infection. Rattiness was associated with infection risk at all elevation levels (OR 1.17 95%CI 1.01, 1.42), but more strongly at high elevations (OR 1.52 95%CI 1.23, 1.87). This relationship was the same in the dry and rainy seasons. These findings provide evidence for two key Leptospira spillover mechanisms. Rat shedding close to the household acts as a source of baseline infections throughout the year, particularly in higher elevation areas where flood-driven pathogen dispersion is limited. Periods of intense rainfall then drive excess infections through large flooding-associated outbreaks. In addition to informing targeted intervention for urban leptospirosis, this study provides a methodological basis to model interactions between reservoirs, environment and human risk behaviours which may be generalisable to other One Health threats with complex epidemiology.

BREAKING TRANSMISSION: A TRANSDISCIPLINARY ONE HEALTH APPROACH TO IMPROVE HOOKWORM CONTROL

Vito Colella[1], Patsy A. Zendejas-Heredia[1], Virak Khieu[2], Susana Vaz Nery[3], Robin B. Gasser[1], Rebecca J. Traub[1], Martin Walker[4]

[1]The University of Melbourne, Melbourne, Australia, [2]Ministry of Health, Phnom Penh, Cambodia, [3]The University of New South Wales, Sydney, Australia, [4]Royal Veterinary College, Melbourne, Australia

Hookworm disease is a major global public health concern, despite targeted control programs of at-risk populations. The success of these programs has been hindered by the rapid re-infection rates linked to persistent reservoirs and the low sensitivity of conventional coprodiagnostic techniques employed.In study 1, we used standard faecal flotation (SFF) and a multiplex qPCR assay to calculate and compare species-specific cure and egg reduction rates of single dose albendazole (400 mg) against hookworm infections at community level. In study 2, we combined microscopic and molecular typing to unveil infections by hookworm-like parasites in people in rural communities. In study 3, we developed a novel multi-host (dog and human) transmission model of Ancylostoma ceylanicum, the main zoonotic hookworm in Asia, and compare the effectiveness of human-only and "One Health" (human plus dog) MDA strategies under a range of eco-epidemiological assumptions.We revealed a substantial difference in cure rate of hookworm infection(s) following albendazole treatment using the SFF (81.5%) and mqPCR (46.4%) assays, and provide the first data on the efficacy of this drug against the zoonotic hookworm A. ceylanicum. In study 2, we identified infections with Trichostrongylus spp. of livestock origin and spurious passage of Melodoygine eggs in people living in remote communities. Finally, we show that One Health interventions—targeting both dogs and humans—could suppress prevalence in humans to ≤ 1% by the end of 2030, even with only modest coverage (25-50%) of the animal reservoir. With increasing coverage, One Health interventions may even interrupt transmission.These findings show that the adoption of refined a transdisciplinary One Health

approach is central to monitoring hookworm infections and the success of control strategies, which can ultimately aid in reducing associated morbidity in human populations. We provide evidence that One Health MDA strategy could be highly effective against A. ceylanicum hookworm in endemic regions of Southeast Asia and beyond and will be essential for sustained elimination and reaching the WHO 2030 goals.

BARRIERS AND ENABLERS TO THE IMPLEMENTATION OF THE ANTIMICROBIAL RESISTANCE NATIONAL ACTION PLAN IN MALAWI

Elias Rejoice Maynard Phiri[1], Jessie Mphande[2], Tumaini Malenga[2], Nicholas Feasey[3], Russell Dacombe[3]

[1]Malawi-Liverpool-Wellcome Programme, Blantyre, Malawi, [2]Africa Institute for Development Policy, Lilongwe, Malawi, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Antimicrobial resistance (AMR) is a major threat to global health resulting in over 1 million deaths annually. The WHO Global Action Plan on AMR (2015) was adapted in Malawi, as the National Action Plan (NAP) on AMR, retaining similar objectives. Adaptation of global policies to local contexts often besets by challenges. We therefore conducted a qualitative study to explore barriers and enablers to the implementation of AMR NAP in Malawi. National data collection involved 22 in-depth interviews (IDIs) with policymakers and stakeholders, and 2 series of semi structured interviews with AMR core group members. District data was collected through 15 IDIs with district policymakers within one health sectors in Blantyre and Chikwawa districts. Data was analyzed thematically. Results showed that AMR in Malawi is socially constructed as an issue of one health, development, healthcare policy, health security threat, and innovation. Enablers for the NAP in Malawi include the use of One Health approach; strong Ministry of Health leadership; use of AMR policy champions; political will; and media engagements. Barriers within sectors included lack of priority setting, coordination, relationships, reporting and use of data, capacity, resources, and evidence. Outside MoH, AMR was viewed as a human health issue, there was incomprehension, sectors working and being resourced in silos, lesser engagement in environmental sector, water splits between ministries, duplicated functions among agencies. For improved AMR fight in Malawi, our study recommends updating legislation and enforcement; increasing awareness of communities and politicians; improving data for AMR in humans and animals; linkage and use of "strong" existing programmes e.g., HIV, decentralisation; and increased and reallocation of resources.

De Leo[4], Christopher J E Haggerty[1], Isabela J. Jones[4], Nicolas Jouanard[6], Andrea J. Lund[3], Amadou T. Ly[7], Raphael A. Ndione[7], Justin V. Remais[8], Gilles Riveau[9], Momy Seck[6], Simon Senghor[7], Susanne H. Sokolow[4], Caitlin Wolfe[10]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Cornell University, Ithaca, NY, United States, [3]UC Santa Barbara, Santa Barbara, CA, United States, [4]Stanford University, Stanford, CA, United States, [5]Emory University, Atlanta, GA, United States, [6]SIA, St Louis, Senegal, [7]EPLS, St Louis, Senegal, [8]UC Berkeley, Berkeley, CA, United States, [9]EPLA, St Louis, Senegal, [10]University of South Florida, Tampa, FL, United States

Many communities in low- and middle-income countries globally lack sustainable, cost-effective, mutually beneficial solutions for infectious disease, food, water, and poverty challenges, despite their inherent interdependence. Here, we provide support for the hypothesis that agricultural development and fertilizer use in West Africa increase the burden of the parasitic disease schistosomiasis by fueling the growth of submerged aquatic vegetation that chokes out water access points and serves as habitat for freshwater snails that transmit Schistosoma parasites to >200 million people globally. In a cluster randomized controlled trial where we removed invasive submerged vegetation from water points at 8 of 16 villages (i.e., clusters), control sites had 1.46 times higher intestinal Schistosoma infection rates in schoolchildren and lower open water access than removal sites. Vegetation removal did not have any detectable long-term adverse effects on local water quality or freshwater biodiversity. In feeding trials, the removed vegetation was as effective as traditional livestock feed but 41-179 times cheaper and converting the vegetation to compost provided private crop production and total (public health plus crop production benefits) benefit-to-cost ratios as high as 4.0 and 8.8, respectively. Thus, the approach yielded an economic incentive—with important public health co-benefits—to maintain cleared waterways and return nutrients captured in aquatic plants back to agriculture with promise of breaking poverty-disease traps. To facilitate targeting and scaling of the intervention, we lay the foundation for using remote sensing technology to detect snail habitat. By offering a rare, profitable, win-win approach to addressing food and water access, poverty alleviation, infectious disease control, and environmental sustainability, we hope to inspire the interdisciplinary search for planetary health solutions to the numerous and formidable, co-dependent global grand challenges of the 21st century.

5082

APPLYING A ONE HEALTH DISPARITIES FRAMEWORK TO ADDRESS THE SOCIAL GRADIENT AND HEALTH DISPARITIES OF BLASTOCYSTIS SP. INFECTION IN NORTHEAST MADAGASCAR

Alma Solis[1], Angela Anaeme[1], Georgia Titcomb[2], Mark Janko[1], Michelle Pender[1], Jean Y. Rabezara[3], Tyler Barrett[1], Randy Kramer[1], Hillary Young[4], Charles Nunn[1]

[1]Duke University, Durham, NC, United States, [2]Colorado State University, Fort Collins, CO, United States, [3]Centre Universitaire Régional de la SAVA, Antalaha, Madagascar, [4]University of Santa Barbara, Santa Barbara, CA, United States

Blastocystis sp. is a globally distributed enteric protozoan parasite that infects humans and a wide range of non-human animals. Its global distribution and wide host range contribute to its high prevalence and strain diversity in humans and other animals, particularly in low-income countries, where it is estimated to infect 30-60% of people. By applying the One Health Disparities framework, our research aims to study exposure disparities by identifying characteristics that expose some community members more than others to Blastocystis sp. We used a mixed-methods approach to investigate the predictors of Blastocystis sp. infection in a population of rural small stakeholder farmers in northeast Madagascar undergoing rapid change in their natural environments. We hypothesized that low socio-economic status, low educational attainment, low health literacy, hygiene practices, and high animal contact would increase the risk of Blastocystis sp. infection. We surveyed and collected fecal samples from 184 adults in one rural village. Fecal samples were screened using DNA metabarcoding, and predictions were tested using generalized linear models (GLM). We found that 64% of participants were infected with Blastocystis sp. representing 114 genetic variants and 4 subtypes. We identified Blastocystis sp. infection risk was higher in individuals who were middle aged (46-60 years old; 18-25 year reference category), lived in a house with wood plank flooring (concrete flooring reference category), washed hands with only water (soap and water reference category), and increased interactions with poultry (rodent reference category). The results suggest that demographic, socio-economic, hand hygiene, and animal interactions influence infection with Blastocystis sp. and highlight health interventions to mitigate zoonotic disease transmission in a low-resource setting. Future research could investigate whether Blastocystis sp. infections are associated with specific disease symptoms, or if they instead represent asymptomatic infections.

5083

EMERGENCE AND SPREAD OF HEARTLAND AND BOURBON VIRUSES IN NEW YORK STATE

Alan P. Dupuis II[1], Rachel Elizabeth Lange[2], Melissa Prusinski[3], Joseph G. Maffei[4], Cheri A. Koetzner[4], Lindsey Tomaszek[4], Bryon Backenson[3], Laura D. Kramer[4], Alexander T. Ciota[4]

[1]Arbovirus Laboratory, Wadsworth Center NYSDOH, Slingerlands, NY, United States, [2]University at Albany School of Public Health and Wadsworth Center, Albany, NY, United States, [3]Bureau of Communicable Disease Control, New York State Department of Health, Albany, NY, United States, [4]Arbovirus Laboratory, Wadsworth Center NYSDOH, Albany, NY, United States

Heartland virus (HRTV, Phenuviridae: Bandavirus) and Bourbon virus (BRBV, Orthomyxoviridae: Thogotovirus) are emerging tickborne viruses in the United States (US). HRTV and BRBV were both identified from human cases in the Midwestern US in 2009 and 2014. Since the discovery of HRTV, more than 60 cases have been recorded in 14 states and at least 4 cases of BRBV in 3 states. Vector surveillance conducted during epidemiological investigations for HRTV and BRBV and results of experimental infection studies led to the incrimination of Amblyomma americanum as the vector for both viruses. While A. americanum are typically found in midwestern and southern regions of the US, this species has experienced a recolonization of former territory and an expanded geographic range now extends as far north as southern coastal Maine. Passive surveillance through commercial laboratory testing first identified HRTV and BRBV in New York State (NYS) in 2018 and 2019, respectively. Enhanced surveillance efforts conducted in Suffolk County since have consistently detected the viruses in A. americanum with high seropositivity rates observed in white-tailed deer. To further our understanding of the emergence and spread of these viruses in NYS and the northeastern US, we conducted full genome sequencing and phenotypic characterization on HRTV and BRBV isolates from 2018-2022. Preliminary sequencing results revealed the existence of distinct clades of both HRTV and BRBV when compared to midwestern isolates. Characterization in cell culture and experimentally infected A. americanum revealed little phenotypic distinction among and between the midwestern and NYS HRTV isolates. NYS BRBV isolates, however, display high levels of both genetic and phenotypic variability compared to each other and representative midwestern BRBV isolates. We also found BRBV but not HRTV NY isolates infect and replicate in Ix. scapularis following virus immersion. Genotypic divergence of both HRTV and BRBV suggest multiple, separate introductions of each virus into NYS with emergence of varying phenotypes potentially due to adaptation to geographically distinct transmission cycles.

5084

INTERSPECIES CO-FEEDING TRANSMISSION OF HEARTLAND VIRUS BETWEEN A NATIVE TICK SPECIES, AMBLYOMMA AMERICANUM, AND THE INVASIVE EAST ASIAN TICK, HAEMAPHYSALIS LONGICORNIS

Parker D. Norman, Clemence Obellianne, Meghan E. Hermance

University of South Alabama College of Medicine, Mobile, AL, United States

The Asian Longhorned Tick, Haemaphysalis longicornis, is an invasive species from East Asia that has recently established populations in 18 states in the U.S. and continues to expand its geographic range. In its native range, H. longicornis is the main vector of the bandavirus, Severe Fever with Thrombocytopenia Syndrome virus (SFTSV). SFTSV is genetically closely related to Heartland virus (HRTV), an emerging North American tick-borne bandavirus responsible for human disease cases in the midwestern, northeastern, and southern United States. Our laboratory recently demonstrated that H. longicornis ticks can transovarially transmit HRTV, and we also have evidence suggesting horizontal transmission of HRTV from H. longicornis to vertebrate hosts. The main vector species for HRTV is the native Amblyomma americanum tick, which shares overlapping geographic territory with the invasive H. longicornis tick. In recent field studies, all three life stages of invasive H. longicornis have been detected feeding alongside native A. americanum ticks on the same host animals (e.g., deer, raccoons, opossums). Consequently, we hypothesize that invasive H. longicornis ticks co-feeding with native HRTV-infected A. americanum can acquire virus independent of host viremia, and that co-feeding HRTV transmission is dependent on localized skin infection. Using an in vivo tick transmission model, we tested our hypothesis by co-feeding HRTV-infected A. americanum nymphs with uninfected H. longicornis larvae or nymphs and screened the fed H. longicornis ticks for the presence of HRTV at different co-feeding proximities on the host. Using q-RT-PCR, HRTV RNA was detected in fed H. longicornis larvae and nymphs collected from multiple mice, providing evidence of interspecies co-feeding transmission of HRTV. Interestingly, this interspecies co-feeding transmission of HRTV occurs in the absence of host viremia; therefore, it is possible that a localized skin infection facilitates HRTV transmission between co-feeding ticks in the absence of host viremia. Experiments are underway to further examine the role of host skin in co-feeding transmission of HRTV.

5085

BORRELIA BURGDORFERI ENZOOTIC CYCLE IN CONSTANT FLUX

Heidi Goethert[1], Richard Johnson[2], Patrick Roden-Reynolds[2], Sam Telford[1]

[1]Tufts Cummings School of Veterinary Medicine, Grafton, MA, United States, [2]Martha's Vineyard Tick Initiative, West Tisbury, MA, United States

The enzootic cycle of Borrelia burgdorferi, the agent of Lyme disease, relies on larval deer ticks feeding upon mammalian hosts to acquire infection. White-footed mice are thought to be the most important reservoir for immature deer ticks, but other hosts can also serve as a source of infection. The relative importance of a host is determined by local habitat conditions that often favor certain species. Identification of the dominant reservoir host at individual sites would greatly facilitate risk reduction measures by allowing targeted efforts. However, very little work has been done to understand the stability of host species' contribution to the enzootic cycle over time. Using our established methods for bloodmeal analysis on questing nymphal ticks, we followed two field sites, Martha's Vineyard and Nantucket Island, for 4 years to determine how bloodmeal hosts of nymphal ticks change over time. In addition, we examined the stability of the enzootic cycle at each site by identifying Borrelia-infected ticks by PCR and determining the host from which they had acquired infection. In 2018, mice were the predominant host on Nantucket having fed 58% overall and 63% of the infected nymphs. Over time, this steadily declined to 13% overall and none of the infected ticks. Borrelia rates fluctuated between 12% and 26%, and the hosts responsible for infected nymphs differed each year. On Martha's Vineyard, shrews were the dominant host for ticks in 2019, feeding 37% overall. However, they fed only 18% of infected ticks. Instead, mice were the predominant reservoir host, having fed 41% of the infected nymphs, despite only having fed 15% overall. Shrews remained the dominant host throughout the study, but the prevalence of infection steadily dropped from 17% to 5%. We conclude that the enzootic cycle of B. burgdoferi is in constant flux; the species contributing Borrelia-infected ticks at a single site can vary greatly from year to year. Furthermore, the species that feeds the most ticks may not be the most important source of infection.

5086

SPATIOTEMPORAL EVOLUTION OF LYME DISEASE IN NORTH CAROLINA FROM 2010 TO 2020

Neha V. Mokashi, Amanda Brown Marusiak, Dana Giandomenico, Annie Green Howard, Paul L. Delamater, Ross M. Boyce

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Lyme disease is the most common vector-borne disease in the United States with a majority of cases occurring in the Northeast and upper Midwest. While historically a low incidence state, North Carolina (NC) has seen substantial increases in reported Lyme disease cases over the past decade. The aim of this study was to characterize the spatiotemporal evolution of Lyme disease in NC from 2010 to 2020. Confirmed and

probable cases reported to the NC Division of Public Health were included in the analysis. Cases with a documented travel history to high or medium-transmission states were excluded. The study period was divided into four subperiods: 2010-2012, 2013-2015, 2016-2018, and 2019-2020. Data were aggregated by zip code of residence of the identified case. Absolute change in incidence per 100,000 from 2010-2012 to 2019-2020 was mapped to identify zip codes with the largest changes. Global and local spatial autocorrelation analyses were performed to evaluate the overall distribution of cases and identify high incidence zip codes with high incidence neighboring zip codes (i.e., hotspot areas) for each period. Overall, we found the largest absolute changes in incidence, up to 464.7 cases per 100,000 people in zip codes located in Ashe County, in the northwestern part of the state and extending towards Buncombe County. The distribution of cases became increasingly and significantly clustered over the study period, from a Moran's I of 0.012 ($p = 0.126$) in 2010-2012 to a Moran's I of 0.403 ($p < 0.05$) in 2019-2020. Hotspots included 22 high incidence zip codes in the 2019-2020 subperiod in the northwestern part of the state, largely co-located with areas experiencing the largest absolute changes in incidence. The results demonstrate the rapid emergence of Lyme disease in northwestern NC over the past decade. Incidence rates in many of the highest transmission zip codes now approach those reported in high-transmission states such as Maine and Rhode Island. Efforts targeted to these geographic areas are urgently needed to educate local residents, medical providers, and public health officials in order to prevent and ultimately reduce the burden of Lyme disease.

5087

ECO-EPIDEMIOLOGY OF RICKETTSIA SPP. IN RURAL ANDEAN COMMUNITIES: FIRST REPORT OF R. MONACENSIS AND R. RAOULTII-LIKE ORGANISMS IN SOUTH AMERICA AND THEIR POTENTIAL VECTORS

Winnie Contreras[1], Cusi Ferradas[1], Marco Risco[1], Luis Mosto[1], Oliver Bocanegra[1], Laura Backus[2], Victor Pacheco[3], Evan M. Bloch[4], Andrés G. Lescano[1]

[1]Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia (UPCH), Lima, Peru, [2]Department of Medicine and Epidemiology, School of Veterinary Medicine, University of California, Davis, CA, United States, [3]Universidad Nacional Mayor de San Marcos, Natural History Museum, Lima, Peru, [4]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Tick-borne rickettsioses are emerging zoonoses with public health implications. In the Andean region of Piura, northern Peru, a seroprevalence of Spotted Fever Group rickettsiae of 10-19% was reported in humans. In addition, the vector of Babesia microti has been found infesting domestic animals in this region. The close contact of rural Andean human populations to potential reservoirs of these tick-borne diseases and their vectors highlights the emerging risk of pathogen spread. We conducted a cross-sectional study in five rural Andean communities in Piura, to improve the understanding of the epidemiology and enzootic ecology of Rickettsia spp. and Babesia spp. We collected dried blood samples from febrile human patients, and ectoparasites and tissue samples from wild and peridomestic rodents. We used real time-PCR (qPCR) targeting the rickettsial conserved gltA gene, and conventional PCR targeting the Babesia 18S rRNA gene to screen all samples. Ticks that were positive for Rickettsia spp. were amplified using conventional PCR for the 17 kDa gene followed by Sanger sequencing. Of the 23 ticks collected, 3 (13%) were qPCR-positive for Rickettsia spp. The 17 kDa amplicon derived from one Ixodes boliviensis tick showed a high degree of similarity to R. monacensis (99.3-99.5%), while another from a tick in Amblyomma maculatum species complex was 100% identical to R. raoultii. Of the 130 rodents captured, 2 (1.5%) were qPCR-positive for Rickettsia spp. (Rattus rattus and Akodon mollis). All 32 human samples were qPCR negative for Rickettsia spp. and all samples were PCR negative for Babesia spp. This is the first molecular detection of R. monacensis and R. raoultii-like organisms in South America, expanding their geographic range beyond Europe and Asia. Results indicate that Rickettsia spp. are circulating among peridomestic and wild rodents and their ticks. An evaluation of vector competence and capacity will be crucial to elucidate whether the A. maculatum species complex is among the vectors of R. raoultii-like organisms. Sequencing of all 17kDa positive samples using gltA and sca5 genes is ongoing to confirm rickettsiae circulation.

5088

SCRUB TYPHUS OUTBREAK IN AUSTRALIAN MILITARY PERSONNEL

Rebecca Suhr, Samantha Nind, **Fiona McCallum**

ADFMIDI, Brisbane, Australia

Scrub typhus (Orientia tsutsugamushi) is a bacterial disease transmitted following the bite of an infected mite. A recent outbreak involving 24 personnel from two Australian Defence Force (ADF) infantry units occurred following separate training events conducted at Cowley Beach Training Area (CBTA), northern Queensland, during June 2022.Investigation of this outbreak highlighted the potential severity as well as the difficulty in accurate diagnosis of the disease. Seven of the 24 diseased personnel presented to hospital, with five admitted. All hospitalized soldiers responded to doxycycline treatment. Challenges to diagnosis and accurate case classification included initial difficulties in recognising case clustering following geographic dispersion of personnel post-training exercise, large numbers of cross-reactive serological results flagging positivity to unrelated infections, requirements for repeat blood testing to inform serological diagnosis, and the need to specifically request scrub typhus serology, in addition to standard rickettisal diagnostic tests, through the contracted pathology service provider. Investigation findings regarding the use of relevant personal protective measures including doxycycline prophylaxis, and associated barriers, will also be presented. Rickettsial disease is recognised as a likely underdiagnosed cause of pyrexia in people in disease endemic regions, including Northern Queensland. Outbreak occurrence highlights the need for improved understanding regarding the geographic and ecological risk factors for disease. Diagnostics for forces that may be deployed in austere environments in the Western Indo-pacific region also require improvement.

5089

ESTIMATING THE SEROINCIDENCE OF SCRUB TYPHUS USING ANTIBODY DYNAMICS FOLLOWING INFECTION

Kristen Aiemjoy

University of California Davis, Davis, CA, United States

Scrub typhus is an acute febrile illness caused by the bacterium Orientia tsutsugamushi. Characterizing the population-level burden of scrub typhus is challenging due to the lack of accessible and accurate diagnostics. We describe a new approach using information about seroresponse after infection to generate population-level scrub typhus seroincidence estimates. We use data from two clinical studies of scrub typhus patients enrolled in Chiang Rai, Thailand, and Vellore, India, and representative population data from two serosurveys in and around the Kathmandu valley, Nepal, and Vellore, India. The samples were tested for IgM and IgG responses to Orientia tsutsugamushi-derived recombinant 56-kDa antigen using commercial ELISA kits. We used Bayesian hierarchical models to fit two-phase models to the antibody responses from scrub typhus cases and used the joint distributions of the peak antibody titers and decay rates to estimate population-level incidence rates in the cross-sectional serosurveys. We compared this new method to a traditional cut-off-based approach for estimating seroincidence. Among 18 to 29-year-olds, the seroincidence of scrub typhus was 886 (95% CI 432-1817) per 100,000 person-years in India and 945 (95% CI: 616-1449) per 100,000 in Nepal. Seroincidence rose with age, reaching a rate of 3231 (95% CI: 2630-3969) per 100,000 among 50 to 89-year-olds in Vellore, India. The seroincidence rates estimated using a cutoff were half the rates we estimated using antibody dynamics. The approach described here can be deployed prospectively,

coupled with existing serosurveys, or leverage banked samples to rapidly characterize scrub typhus burden and generate scrub typhus seroincidence estimates that are comparable across populations, regions, and time.

A CONTENT REVIEW OF COVID-19 RELATED APPS USED IN VIETNAM

Linh Tran[1], **Nguyen Thanh An**[1], Federica Cucé[2], Kadek Agus Dila[3], Nguyen Hai Nam[4], Doan Le Nguyet Cat[5], Lee Wei Jun[6], Farrukh Ansar[7], Fatima Abdallh[8], Au Vo[9], Nguyen Tien Huy[10]

[1]Duy Tan University, Da Nang, Viet Nam, [2]University hospital of Verona, Verona, Italy, [3]Giri Emas Hospital, Bali, Indonesia, [4]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [5]Fleetwood Park Secondary School, Surrey, BC, Canada, [6]International Medical University, Kuala Lumpur, Malaysia, [7]Khyber Medical University, Peshawar, Pakistan, [8]Hashemite University, Zarqua, Jordan, [9]University of California, Los Angeles, CA, United States, [10]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan

Various digital applications (apps) have been developed to combat the spread of COVID-19. In Vietnam, many COVID-19 apps have been launched by private developers or the Ministry of Health with overlapping features and purposes, which greatly confused Vietnamese residents. This problem has raised a concern about the usefulness and effectiveness of these apps during the pandemic in Vietnam. We aim to evaluate all current Vietnamese COVID-19 apps including features, purposes and functionality, advantages, disadvantages, and ethical issues of each app, to eventually provide reliable resources for the Vietnamese government to develop a unique national COVID-19 app. We conducted a systematic and manual search on 1st October 2022, on PubMed, Scopus, Google, and BBC New's official website to identify all available COVID-19 apps in Vietnam. The relevant apps were discussed to reach a consensus and comply with a list of included apps for further assessment. Thirty Vietnam-based COVID-19 mobile apps were identified in the Apple and Google Play Store, which were evaluated through opinions on these stores, along with an analysis carried out by the research team members. These are duplicated features and functions among apps detected and some apps have lacked important functionality such as vaccination-related features. It is crucial to develop one complete app that fulfills the most useful features, addresses the common errors, and replaces all current apps to facilitate user experience.

5092

COMPREHENSIVE COST-EFFECTIVENESS ANALYSIS OF A NEW COMPARTMENTAL MODEL FOR BACTERIAL MENINGITIS CONSIDERING THE INFLUENCE OF THE MEDIA

Yarhands Dissou Arthur[1], Joshua Kiddy K Asamoah[2], Alexander Kwarteng[2]

[1]akenten Appiah-Menka University Of Skills Training And Entrepreneurial Development, Kumasi, Ghana, [2]kwame Nkrumah University Of Science And Technology, Kumasi, Ghana

Mathematical epidemiology has paid some attention to the study of bacterial meningitis because of the severity of the disease and the way it spreads through a population. In this paper, we formulated a new compartmental model for meningitis to study the impact of media on reducing the severity of the disease in Ghana. We obtain the control reproduction number and the herd immunity rate in the presence of vaccination. We noticed that the meningitis death rate could be controlled with an increase in publicity of the dynamics of the spread of the disease and the ability to seek immediate medical treatment. We conduct a sensitivity analysis using Latin hypercube sampling. It is noticed that the transmission rate, vaccination, and the media have a negative nonlinear correlation. The effects of media, vaccination and treatment as a function of time are also investigated using an optimal control model. We display the efficiencies of the controls and demonstrate the mean and incremental cost-effectiveness ratios. The cost of controlling meningitis in the presence of media, vaccination, and treatment is discussed, and we hope this study will further educate the public on this topic.

5094

COST-EFFECTIVENESS ANALYSIS OF FOURTH GENERATION RAPID DIAGNOSTIC TESTING FOR HIV AMONG MEN WHO HAVE SEX WITH MEN IN NIGERIA

David Wastlund[1], Rebecca Sim Shu Yu[1], **Michelle Sotak**[2]

[1]Vista Health Pte Ltd, Singapore, Singapore, [2]Abbott, Abbott Park, IL, United States

Fourth-generation HIV rapid diagnostic tests for HIV include both HIV antibodies and p24 antigen, increasing the ability to detect acute HIV infections. The study compared the costs and health outcomes of using fourth-generation rapid diagnostic tests to third-generation (antibody-only) tests when screening men who have sex with men (MSM) from a health system perspective in Nigeria. A health economic cost-effectiveness model was developed to compare outcomes for different screening options. A decision-tree structure was used for evaluating the screening outcomes based upon the diagnostic accuracy and timing of the test. Health and costs associated with the different screening outcomes were modelled using a Markov-based framework to reflect clinical progression of HIV infection with early and late treatment. The population was modelled throughout a lifetime horizon, and captures costs, quality-adjusted life years (QALYs), disability-adjusted life years (DALYs), and transmission of new cases. Input parameters were derived from local sources where available and adapted from regional estimates where Nigeria-specific estimates were lacking. Given the absence of HTA guidelines in Nigeria, an international reference case for economic evaluation in low-middle income countries was used. Given an assumption that 0.7% of patients are pre-seroconversion at the point of testing, screening MSM who are unaware of HIV status yields an additional cost of US $2,260 per DALY averted, and US $802 per QALY gained, both of which are below Nigeria's GDP per capita. The relative value of fourth-generation tests increases with a higher proportion of cases with asymptomatic and acute infections. The analysis shows that switching to fourth-generation tests may be an effective strategy for improving detection of new cases - especially those who are pre-seroconversion - and prevent further transmission of HIV at a feasible cost.

5096

DIGITIZATION OF THE NATIONAL LONG ACTING INSECTICIDE TREATED MOSQUITO NET MASS DISTRIBUTION CAMPAIGN IN GUINEA: PROCESS, CHALLENGES AND LESSONS LEARNED

Abdourahamane Diallo[1], Moustapha Camara[1], Fatoumata Battouly Diallo[2], Mamadou Sitan Keita[3], Agossa Charles Lebon LAWSON[2], Mohamed Saran CONDE[2], Mamadou Bhoye Diallo[3], Alioune Camara[1]

[1]National Program for Malaria Control, Conakry, Guinea, [2]Catholic Relief Services, Conakry, Guinea, [3]Notre Santé / RTI, Conakry, Guinea

In Guinea, mass distribution of Long-Acting Insecticidal Nets (LLINs) is a key component of malaria prevention strategies and has contributed to a significant decrease in malaria prevalence since 2013. In 2022, the country implemented the first ever digitization of the fourth, tri-annual national LLIN distribution campaign to improve data quality and optimize the different stages of the campaign. The purpose of this study was to analyze the implementation process and document the challenges and lessons learned from this digitization. We conducted a descriptive study to document the planning and implementation of the campaign stages. A mobile application called "MILDA2" integrated with the District Health Information Software 2 (DHIS2) was used to enumerate households, scan QR codes for distribution and manage the flow stock of LLINs in real time. Campaign results, challenges encountered, and lessons learned are described in this work. A total of 17,160,359 individuals were enumerated (< 5.8% of the projection) among 2,746,044 households nationwide, which was 4% more than the

micro-planning projections, corresponding to an average of 6.2 people per household. 8,927,983 LLINs were distributed nationally for a total of 2,511,150 households served (i.e., 91.4% of the households enumerated). 16,473,945 people (96%) were covered by LLINs (1 LLIN for every 1.9 people). With the support of its partners, Guinea successfully conducted its first fully digitized national LLIN campaign in 2022. Despite myriad challenges in the planning and implementation of the campaign, digitization improved data completeness, transparency in LLIN management, and geographic coverage. Maintaining this innovation is essential for future, effective mass campaign implementations for better malaria prevention and control in Guinea.

5097

SYSTEMATIC REVIEW AND META ANALYSIS ON PREVALENCE OF ORAL SUBMUCOUS FIBROSIS

Savitha Satish

Johns Hopkins Bloomberg School of Public Health, South Windsor, CT, United States

Systematic Review and Meta analysis on prevalence of Oral SubmucousFibrosis.ABSTRACTOral submucous fibrosis (OSF) is a potentially malignant condition, linked to the causativehabit of chewing areca nut. Since the discovery of this condition in the 1960s, numerousepidemiological studies have been conducted to assess its prevalence. With the proliferationof commercially available areca nut products and its increasing popularity amongst the youth,the prevalence has been on the rise. The present meta analysis was initiated to collate andanalyse the data on the prevalence of the condition in India and different parts of the world.Literature search from databases like Pubmed, PubGet, NLM, Ovid, Medline, Cochrane andElsevier was conducted using specific keywords. The search period ranged from 1960 to2022. After screening the studies based on inclusion and exclusion criteria, data on studydesigns, associated habits, prevalence rates, country of study were extracted. Meta analysisusing random effects model was performed to obtain pooled prevalence rate. Additionally,subgroup analysis, funnel plot and sensitivity analysis were also performed. The pooledprevalence of OSF among the included 61 studies was 9% (95% CI:5% to 35%). Majority ofthe studies were conducted in Asia (95.1%) and 52 studies belonged to India. The prevalenceof OSF varied from least being 0.03% to highest rate of 85.5% in the present study. Thefunnel plot and Egger's test indicated presence of publication bias. The present meta-analysisreview shows that reported prevalence rates of OSF in worldwide vary in wide degreedependent upon the region and sample size. The variation in a large part is also due to skewedand biased study designs and sample selections. Thus, the need for a comprehensiveepidemiological survey spread across many countries to assess the prevalence rate of OSFbecomes even more necessary.

5098

WHO ESPEN COUNTRY HEALTH INFORMATION PLATFORM

Alexandre Laurent Pavluck

Sightsavers, Covington, GA, United States

The Country Health Information Platform (CHIP) is a web-based data visualization tool, utilizing cloud hosting, web-APIs, and business intelligence software, that allows anyone to review key NTD data from official annual reporting forms submitted to the World Health Organization (WHO) and the International Trachoma Initiative (ITI). These annual forms are single year forms that report on endemicity for the five PC-NTDs, treatments delivered to eliminate these NTDs, and the impact surveys conducted to determine the future treatment strategy. Because the forms are single year, and elimination of PC-NTDs as a public health problem requires multiple years of intervention, CHIP presents these data overtime to assist national programmes and partners to make informed decisions using these data. Since launching 2021, CHIP as been scaled up to be available to all countries with an active NTD programme in the WHO African region. We will use this poster session to present the tool, highlight the functionality, and present the results from pre-test and post-test training surveys.

5099

HEALTH AND ECONOMIC IMPACTS OF SUBSTANDARD UTEROTONICS IN GHANA AND NIGERIA

Yi-Fang (Ashley) Lee[1], Colleen R. Higgins[1], Petra Procter[2], Sara Rushwan[2], A. Metin Gülmezoglu[2], Lester Chinery[2], Sachiko Ozawa[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Concept Foundation, Geneva, Switzerland

The study is to advance Universal Health Coverage (UHC) by building the evidence base on the threat that substandard uterotonics pose to postpartum hemorrhage (PPH) and maternal mortality. We modeled the use of substandard uterotonics in preventing PPH and assessed the health and economic burden on governments, healthcare providers, payors, and families in Ghana and Nigeria. A decision-tree model was built to simulate vaginal and cesarean section delivery, quality of uterotonics and their use, and risk of PPH. We then compared scenarios results with and without substandard uterotonics. The model simulated women giving birth in different settings based on their characteristics using data from countries' Demographic and Health Survey. Use of uterotonics by delivery setting and subsequent steps of treatment were simulated. Literature and key informants were utilized to generate model inputs and assumptions. Risks of health outcomes were abstracted from a Cochrane review on the effect of uterotonics. Data from the E-MOTIVE trial was used to model health outcomes based on oxytocin quality. Data on quality of the commonly used uterotonics were also utilized. We estimated that millions of mothers in Ghana and Nigeria receive poor-quality uterotonics annually, resulting in hundreds of thousands of preventable PPH cases. Without substandard uterotonics, healthcare providers could reduce uterotonic use and save on blood transfusions, while averting thousands of maternal deaths due to PPH. Substandard uterotonics also led to out-of-pocket and insurance costs for additional treatments, blood transfusions, and longer hospitalizations, placing an avertable economic burden on families and governments. The study demonstrates that use of quality-assured uterotonics would result in economic savings and a reduction in occurrence of PPH. Reducing the health and economic burden of PPH in low-resource settings is essential toward decreasing maternal mortality. This underlines the importance medicines quality assurance systems play for country governments to scale the implementation of UHC.

5100

SPATIOTEMPORAL ANALYSIS OF THE RELATIVE RISK OF POST-INFECTIOUS VERSUS NON-POST-INFECTIOUS HYDROCEPHALUS AND ITS RELATIONSHIP WITH ENVIRONMENTAL FACTORS

Lucinda Hadley

Lancaster University, Lancaster, United Kingdom

The bacteria, Paenibacillus thiaminolyticus, has recently been identified as contributing to neonatal sepsis and subsequent post-infectious hydrocephalus (PIH) in Ugandan infants. The absence of infection in mothers suggests that the infants must have been exposed to the bacteria in the first days of life. The biogeography of P. thiaminolyticus is currently unknown, however, the spatiotemporal distribution of patients with PIH shows evidence of inhomogeneity. Based on an observed seasonal increase in PIH cases when the rains come in, it is hypothesized that the distribution of the bacteria is related to environmental variables. This work uses data collected over a 20-year period by the CURE Children's Hospital of Uganda (CCHU) in Mbale on infants with hydrocephalus. The data includes cases of PIH and non-post-infectious hydrocephalus (NPIH). By using NPIH as the control population we estimate the relative risk (RR) of PIH. We assume that the point pattern data given by the spatiotemporal coordinates of the PIH and NPIH cases are realizations of two underlying inhomogeneous Poisson point processes. By examining the ratio of their intensities, we are able to fit a logistic model to the data. Our model identifies areas of elevated RR which can be utilized to inform diagnostics and treatment at point-of-care. We demonstrate increased RR i) spatially: in the area north-west of lake Kyoga, throughout the study period and

ii) temporally: for the years 2006-2012, across the whole of Uganda. By incorporating information on environmental variables, including rainfall, temperature, and the Standardized Precipitation Evapotranspiration Index (SPEI), we can explain some of this increased RR. In particular, we find evidence of a significant positive association between RR of PIH and rainfall. By incorporating real-time data, the model can be used to predict times, locations, and environmental conditions with increased risk of PIH, to inform preventative measures, and to direct further studies into the biogeography of P. thiaminolyticus.

IS SUB-SAHARAN AFRICA READY FOR DIGITAL CLINICAL TRIALS?

Dawit Asmamaw Ejigu[1], Eyasu Makonnen[1], Thy Pham[2], Brenda Okech[3], Kristin Kristin Croucher[4], Abebaw Fekadu[1]

[1]CDT-Africa, Addis Ababa, Ethiopia, [2]Bill & Melinda Gates Foundation, Washington, WA, United States, [3]UVRI-IAVI, HIV Vaccine Program, Entebbe, Uganda, [4]6.Lightship, London, United Kingdom

Digital Clinical trials, also known as Decentralized Clinical Trials (DCTs), leverage digital technologies to facilitate recruitment/ retention, data collection, and analyses and hence, increase the efficiency of clinical trials in developing interventions against various health problems. DCTs are gaining traction after their iterative implementations during the COVID-19 pandemic. Guidelines and recommendations for implementing DCTs in developed countries are in their formative stage, while applicable recommendations for developing countries are yet to be described. DCTs have several utility features, which make them very attractive for implementation in Sub-Saharan Africa (SSA). Opportunities that enable the implementation of DCTs in the continent, such as an increasing trend in innovative health technologies, are also flourishing in the continent. However, several potential challenges still require a workaround before implementing such trials in SSA. This paper highlights the potential opportunities and challenges surrounding the implementation of DCTs in SSA and puts forward suggestions on how to exploit the opportunities and address the challenges. The paper also highlights the survey's findings on the perceptions of experts with experience conducting DCTs in SSA on the opportunities and challenges of implementing DCTs in the continent.

5102

SPATIO-TEMPORAL OCCURRENCE, BURDEN, RISK FACTORS AND MODELLING METHODS FOR ESTIMATING SCRUB TYPHUS BURDEN FROM GLOBAL TO SUBNATIONAL RESOLUTIONS: A SYSTEMATIC REVIEW

Qian Wang[1], Tian Ma[2], Fangyu Ding[3], Kartika Saraswati[1], Benn Sartorius[4], Nicholas Philip John Day[1], Richard James Maude[1]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Institute of Geographic Sciences and Natural Resources Research, Beijing, China, [3]Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China, [4]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Scrub typhus, caused by Orientia tsutsugamushi, poses a significant public health threat, especially in the Asia-Pacific region. This systematic review aims to synthesize the spatio-temporal occurrence, burden, risk factors, and modelling methods for estimating scrub typhus burden across various geographical resolutions (PROSPERO #CRD42022315209). We searched PubMed, Scopus, Web of Science, China National Knowledge Infrastructure and other databases for articles published up to May 2022, with no language restrictions, for studies that quantified the occurrence, burden, risk factors, and modelling methods of scrub typhus. Study quality was assessed using a modified version of the Newcastle-Ottawa Scale. Our database search returned 13,272 articles, of which 2,109 were deemed eligible for full-text review. Ultimately, 640 articles were incorporated into our systematic review and meta-analysis, spanning 29 countries from 1957 to 2020. Overall, the global prevalence of scrub typhus varied significantly across different regions and time periods with seroprevalence among healthy populations ranging from 0% to 30% (median 11.5%). Reported incidence was found to be increasing in countries with established surveillance systems, with China reporting the highest incidence (527.7/100,000). The case fatality rate varies widely by region and time, with India reporting the highest case fatality rate (32.8%). Meteorology, landcover, and human activities were identified as key factors of disease acquisition. Boosted regression trees (BRT), ecological niche modelling (ENM) approach and Bayesian hierarchical models were employed to estimate risk. A substantial global burden of scrub typhus exists, with significant variations in occurrence and distribution across different regions and time periods. The meta-analysis will be continued, and we believe that this comprehensive systematic review will result in more attention for this neglected disease and help establish the research agenda for producing new generalizable information to bridge gaps in comprehension of the burden of scrub typhus.

5103

MATHEMATICAL MODELS OF PLASMODIUM VIVAX MALARIA: A SYSTEMATIC REVIEW

Rachel A. Hounsell[1], Caroline Franco[1], Sheetal P. Silal[2]

[1]University of Oxford, Oxford, United Kingdom, [2]University of Cape Town, Cape Town, South Africa

Plasmodium vivax causes significant morbidity and mortality worldwide. With an extensive geographic distribution and specific considerations for its diagnosis and treatment, P. vivax poses unique challenges for malaria control and elimination. Mathematical modeling is a useful tool to aid decision making. As the scientific community's understanding of P. vivax and mixed infections continues to evolve and expand, there is an opportunity to review and learn from existing models to improve future model development and application. We conducted a systematic literature review of mathematical models of P. vivax malaria transmission. Our aim was to investigate the characteristics, key features, parameter values and evolution of these models; to explore common themes and identify knowledge gaps. We searched MEDLINE, Scopus, Web of Science, and Embase, for articles published in English until 8 August 2022. We included population- and individual-based mathematical models of P. vivax or mixed species models incorporating P. vivax. We excluded pharmacokinetic/ pharmacodynamic models, models that had no human component, and models that were within-host only. Two reviewers independently conducted a title-abstract screen, followed by a full text screen. Disagreements between reviewers were resolved through the authors' consensus. The systematic review yielded 1,923 results. After removing duplicates, we screened 842 abstracts. We screened 105 full text publications, of which 58 were included in the final analysis. We present summary characteristics of the included publications (e.g., geographic focus, species included, type of model, interventions). We identify and discuss key model features, exploring the similarities and differences between model structures and approaches. We show a map of the evolution and relationship between the models. We synthesize model parameter values, presenting the distribution and source of values. Finally we critically discuss gaps and challenges for modeling P. vivax and mixed species infections.

5104

STRATIFICATION OF MALARIA BURDEN AND SUBNATIONAL TAILORING OF INTERVENTIONS TOWARDS TO INFORM THE DEVELOPMENT OF THENATIONAL MALARIA ELIMINATION STRATEGIC PLAN IN GHANA

Samuel K. Oppong[1], Punam Amratia[2], Beatriz Galatas Andrade[3], Abdisalan NOOR[3], Wahjib Mohammed[1], Nana Yaw Peprah[1], Peter Gething[2], Keziah Malm[1]

[1]National Malaria Elimination Programme, Accra, Ghana, [2]Malaria Atlas Project, Telethon Kids Institute, Perth, Australia, [3]Global Malaria Programme, WHO, Geneva, Switzerland

As part of the pillars of HBHI - use of strategic information for decision making, stratification of malaria burden at subnational level is imperative

to inform appropriate interventions to be deployed. In 2022, the name of the Ghana National Malaria Program was changed from Control to an Elimination Programme. This called for a new strategic plan to be developed to reflect the scope and strategies to be implemented under the elimination agenda. This abstract outlines the processes and methods used in developing risk stratification of malaria at district level and tailoring of interventions towards malaria elimination in Ghana. A subnational level of malaria burden was conducted with guidance from WHO to stratify the country according to its epidemiology and transmission risk factors and inform where strategic interventions will be implemented under the elimination framework. Routine health facility data aggregated at district level was combined with prevalence estimates from Malaria Atlas Project (MAP) and All-cause mortality estimates from the Institute for Health Metrics and Evaluation to categorize the districts into very low, low, moderate, and high epidemiological strata. Appropriate interventions and strategies were developed for each strata and discussed with multi-sectorial stakeholders for buy-in and ownership. The plan is to whip up political commitment and ensure all sectors are involved in the further reduction of malaria in the country.

5105

MOLECULAR BIOMARKER IDENTIFICATION IN SEASONAL CARDIOVASCULAR COMORBID DISEASES (SCCD) USING NETWORK METANALYSIS

Apoorv Gupta[1], Jaichand Patel[2], Prince Kumar[3], Kamran Manzoor Waidha[4], Arun K. Sharma[1]

[1]Department of Pharmacology, Amity Institute of Pharmacy, Amity University Haryana, Gurugram, Haryana, India, [2]Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Centre, Omaha, NE, United States, [3]Department of CSIC, PGIMER, Chandigarh, India, [4]Reviana Innovations Pvt. Ltd,, Delhi, India

The start of many illnesses is known to be significantly influenced by seasonal variations in the human cardiovascular system. Confounding variables include behavioral and environmental factors; failure to account for such factors makes determining the real temporal effect of certain disorders challenging. Numerous clinical investigations, on the other hand, suggest that only some groups of people are more seasonal sensitive, and that their maladaptation may contribute to a variety of disorders. As a result, evaluating the etiological and seasonal sensitive patterns of cardiovascular diseases (CVD), which affect the majority of the human population, is crucial. The study's premise was that cardiovascular and related disorders have significant links with seasonal and etiological fluctuations. Thus, in the current study, data mining was used to find 852 disease association connections between cardiovascular and related illnesses from a systematic review of 4519 papers. To focus on only the most prevalent CVDs, a disease ontology-based semantic similarity network (DSN) study was carried out. Furthermore, topological analysis was employed that predicted the seven CVDs in three clusters. The seasonal sensitivity and temporal association of these seven CVDs were then investigated using Mann-Kendall and Cox-Stuart models and their temporal connections were validated using LOESS and TBATS. The study provides indirect evidence of a significant etiological relationship between three cardiovascular diseases, including MI, atrial fibrillation, and atherosclerosis, all of which are seasonal in the majority of the world's population. As a result, these three conditions qualify as seasonal cardiovascular comorbidities (SCCD). Following that, secondary network met analysis using GEO data from GSE2240 (atrial fibrillation) and GSE132651 (atherosclerosis) reveals a triad of NRF1-hsa-miR-124-3p-NRF2 is a physiologically and statically significant module, and both NRF-1 and NRF-2 might trigger a cascade that inhibits GSK-3 phosphorylation. This may minimize the risk of myocardial infarction while also improving heart pathology.

5106

THE ROLE OF BELIEFS IN MALARIA PREVENTION AND TREATMENT BEHAVIOR: ANALYSIS OF THE 2021 NIGERIA MALARIA INDICATOR SURVEY

Indrani Saran, Oladoyin Okunoren

Boston College, Chestnut Hill, MA, United States

Malaria remains a major public health problem globally and especially in Sub-Saharan Africa. In 2021, Nigeria accounted for 26.6% of global cases and 38.4% of global deaths among children under the age of five. Underuse of effective tools for prevention and treatment undermines progress against the disease. For example, recent household surveys from Sub-Saharan Africa suggest that only 47% of the population slept under a net, and 33% of children under the age of five did not receive treatment for a fever. We analyzed the 2021 Nigeria Malaria Indicator Survey to examine how people's knowledge and beliefs about malaria were associated with their prevention and treatment behaviors. The survey included 14,476 women respondents as well as data on 3947 children who had a fever in the two weeks prior to the survey. Preliminary analyses suggest that when controlling for age, wealth quintile, education level, region and residence type (urban/rural), women who had heard a message about malaria in the previous six months had significantly higher odds of sleeping under a bed net (OR=1.21, 95% CI [1.07 1.35]), as did women who believed their families were susceptible to malaria (OR=1.30, 95% CI [1.05 1.60]), who believed malaria was a serious disease (OR=1.16, 95%CI [1.02 1.32]) and who perceived widespread community norms around malaria prevention and treatment (OR=1.42, 95% CI [1.23 1.63]). Hearing a message about malaria, perceived susceptibility to malaria, and beliefs about community norms were also significantly positively associated with children under the age of five getting treatment for a fever outside the home. Our results indicate that people's beliefs play an important role in malaria prevention and treatment behavior. Moreover, the findings suggest that sharing information about malaria, particularly regarding the risk of infection and severity of disease, and highlighting the degree to which the community engages in malaria prevention and treatment behaviors, could be effective strategies to increase both use of bed nets and treatment of fevers.

5107

SYSTEMATIC REVIEW: MATHEMATICAL MODELLING PARAMETERS OF THE NINE WORLD HEALTH ORGANIZATION PRIORITY PATHOGENS

Gina Maria Cuomo-Dannenburg, Sabine van Elsland, Natsuko Imai, Sangeeta Bhatia, Anne Cori, Imperial College Priority Pathogen Group

Imperial College London, London, United Kingdom

Mathematical modelling of infectious pathogens has been extensively used to understand endemic diseases and respond to outbreaks such as Ebola, measles and COVID-19. Modelling is a useful tool to predict infectious disease dynamics, project the likely future epidemic trajectory and estimate the potential impact of interventions to guide the public health response. In 2019, the World Health Organization updated its list of blueprint priority infectious pathogens that pose the greatest public health risk, due to their epidemic potential and/or lack of suitable interventions or therapeutics. We systematically reviewed parameter values, mathematical models and historical outbreaks for all listed pathogens, excluding disease X: Crimean-Congo haemorrhagic fever, Ebola virus disease, Lassa fever, Marburg virus disease, Middle East respiratory syndrome coronavirus, Nipah and henipaviral diseases, Rift Valley fever, Severe Acute Respiratory Syndrome and Zika virus. We searched OVID Medline and EMBASE and Web of Science until 8th March 2019 and retrieved 95,144 results. After title and abstract screening and full-text review, we found 1,684 papers for data extraction. We collate information required to enable rapid mathematical modelling of these nine pathogens including, but not limited to, fatality ratios, mutation rates, reproduction numbers, risk factors, model structure, seroprevalence and historical outbreaks. Our work highlights areas of uncertainty, especially for pathogens having not yet caused large human epidemics, where it is hard to quantify transmission or severity. By looking

at multiple pathogens simultaneously, we can archetype pathogens into profiles based on their characteristics. This will be useful in future epidemics of these pathogens, to rapidly identify existing parameters, models and outbreak data, enable mapping to these typologies for similar novel pathogens and identify potentially effective interventions. This work will serve as the basis for a dynamic database that could be further enriched by other contributors to ensure this review provides a "live" picture of the current knowledge landscape.

5108

GEOSPATIAL MODELLING OF FEBRILE ILLNESS PREVALENCE AMONG CHILDREN AGED UNDER FIVE YEARS IN UGANDA

Misaki Sasanami[1], Paddy Ssentongo[2], Camille Moeckel[2], Claudio Fronterrè[1]

[1]Lancaster University, Lancaster, United Kingdom, [2]Penn State Health Medical Center, Hershey, PA, United States

Febrile illness is still one of the major public health problems in Africa. Although it has been recognised as crucial to better understand the spatial distribution, the evidence is still limited. We aim to predict the prevalence of fever cases among children aged under 5 years in Uganda, whilst exploring the association with potential risk factors. We analyse household records from the 2016 Demographic and Health Surveys (DHS) conducted in Uganda. We develop a geostatistical Binomial model to predict the prevalence of fever cases among children aged under 5 years, accounting for environmental, nutritional, and socio-demographic risk factors obtained from publicly available sources. The median crude (empirical) febrile illness prevalence for each cluster was 30.4% (interquartile range:13.6-50.0). There is extensive within-country spatial variation in children's febrile illness prevalence in Uganda and the model indicates the presence of strong spatial correlation, predicting a higher prevalence in the eastern and north-eastern regions. The model indicates the association with some potential risk factors, and the inclusion of them improves the predictive performance of the model. The findings could assist in targeted public health policy-making for fever case management and in hypothesis generation for aetiology.

5109

THE ROLE OF COMMUNITY HEALTH WORKERS IN TREATMENT MONITORING OF RADICAL CURE FOR PLASMODIUM VIVAX MALARIA IN PAPUA, INDONESIA: A MIXED METHODS STUDY

Annisa Rahmalia[1], Enny Kenangalem[2], Liony Francisca[2], Reynold R. Ubra[3], Ric N. Price[1], Jeanne R. Poespoprodjo[2], Koen Peeters Grietens[4], Charlotte Gryseels[4]

[1]Menzies School of Health Research, Darwin, Australia, [2]Papuan Community and Health Development Foundation, Timika, Indonesia, [3]Mimika Regency Health Office, Timika, Indonesia, [4]Institute of Tropical Medicine, Antwerp, Belgium

Adherence to 14-day regimen of radical cure for Plasmodium vivax malaria is improved by supervision. In a highly malaria endemic area in Papua, Indonesia, clinic staff cannot supervise treatment through home visits due to the high number of cases. As part of strengthening malaria case management, a system was developed for clinic staff to refer patients to community health workers (CHWs) for treatment monitoring. The mechanisms and contexts that underlay the effectiveness of this intervention were assessed in a mixed methods study using realist evaluation. Between May 2019 and December 2022, patient referral to CHWs for treatment monitoring was introduced in five public health clinics. Through meetings with malaria program managers, the need to establish communication channels between clinic staff and CHWs was identified as essential for patient referral. CHW treatment monitoring practices were identified by calculating the proportion of referred patients who were monitored, participant observations at the clinic and patients' homes during visits, and interviews with clinic staff and CHWs. CHWs can succeed in finding and visiting patients when they received complete patient information upon referral. Monthly meetings with clinic staff facilitated CHWs acceptance of treatment monitoring as their task. If the CHWs perceived good communication from clinic staff, there is greater incentive to find patients even without complete information. Identifying non-compliance, such as patients who reduced the number of tablets taken per day or stopped taking drugs, increased CHW confidence in treatment monitoring. When an ACT shortage led to prescription of second line drug (quinine), CHWs became more motivated to monitor treatment out of concern over patients not completing antimalarial treatment. The refined referral system was tested with new CHWs recruited later, confirming the importance of regular communication from clinic staff and complete patient information upon referral. In addition, perception of getting direct positive results (e.g. non-compliant patient becomes compliant) directly influenced CHW treatment monitoring practices.

5110

COVID-19 VACCINATION IN GHANA: THE DISCOURSE OF RELIGION, GENDER, PERCEIVED SAFETY OF VACCINE AND GHANAIANS' READINESS TO BE VACCINATED

Perpetual Adjoa Antobam, Alexander Kwarteng

Kwame Nkrumah University of Science and Technology, KUMASI, Ghana

Covid -19 was declared a global pandemic in 2020 by the world wealth organization due to its global damage it caused to human life and the negative effect on the global economy. To deal with this pandemic was the global plan to vaccinate globally to achieve a herd immunity. The vaccine exercise was faced with some conspiracy theories ranging from vaccine safety and religious believes. This study examine vaccination in Ghana vis-a-vis the religious and safety paradigm. The cross-sectional survey randomly sampled 2000 participants but 1409 properly completed the questionnaire representing 70% response rate. The study reveals that participants willingness to be vaccinated and be part of the first group of people to be vaccinated was dependent on the religious affiliation of the participants (X2=23.9, p-value =0.02). The study further shows that the Ghanaian perception about the safety of the vaccine was also dependent on the religious belief of the participants (X2=25.9, p-value =0.001).The study however revealed that participants perception about the safety of covid-19 vaccine and the willingness to participates in the vaccination was independent on the gender of the respondent. The study finally revealed that participants wiliness to be vaccinated was independent on the gender of the participant. The study concludes that religious belief significantly influenced participants willingness to be vaccinated. The study recommends to the government of Ghana and the Ministry of Health to be sensitive to the religious leaders in their drive to get the Ghanaian people vaccinated to obtain herd immunity.

5111

PREVALENCE, RISK FACTORS AND CONSEQUENCES OF MICROCEPHALY IN LOW- AND MIDDLE-INCOME COUNTRIES: A CALL TO ACTION FOR THE GLOBAL MATERNAL AND CHILD HEALTH COMMUNITY

Molly M. Lamb[1], Olivia Pluss[1], Kirsten Fong[1], Anna Funk[2], Amy K. Connery[3], Alison M. Colbert[3], Thomas Jaenisch[1]

[1]Colorado School of Public Health, Aurora, CO, United States, [2]University of Calgary, Calgary, AB, Canada, [3]Childrens Hospital Colorado, Aurora, CO, United States

The recent Zika Virus epidemic heightened awareness of the high prevalence of microcephaly in infants in low- and middle-income countries (LMICs). Despite being considered a very rare condition in high-income countries (HICs), the prevalence of microcephaly has been found to be up to 5% in LMICs, irrespective of the presence of Zika Virus circulation, indicating a long-running, underrecognized public health concern. However, microcephaly prevalence estimates in LMICs are still sparse and calculation of microcephaly is not standardized. Furthermore, while risk factors for microcephaly have been identified in HICs, the risk factors for microcephaly may be dramatically different in both type and prevalence in LMICs. The

limited available data suggest that generational malnutrition and related intrauterine growth restriction and low birth weight, frequent infections and malnutrition in infancy, and other poverty-related stressors that are much more common in LMICs may be associated with the high prevalence of microcephaly. Finally, emerging evidence demonstrating the association between microcephaly and poor subsequent neurodevelopment in LMICs highlights the serious consequence of high microcephaly prevalence. Therefore, more in-depth understanding of the prevalence, risk factors and consequences of microcephaly in LMICs is urgently needed. We review existing evidence to identify an appropriate definition of microcephaly for research implementation, and recommend that measurement of head circumference be routinely incorporated in clinical and public health practice in LMIC settings. We then describe the factors that have been associated with microcephaly in LMICs and review the evidence on the association between microcephaly and poor neurodevelopment in LMICs. To encourage and guide advancement of this field, we provide a set of recommendations to improve collection, analysis, and interpretation of the risk factors and consequences of microcephaly in LMICs.

5112

ASSESSMENT OF DIETARY HABITS AND IODINE STATUS AMONG PREGNANT WOMEN IN SOUTHERN GHANA

Nana Yaa Asiedua Appiah[1], Frank Hayford[2], Samuel Antwi-Baffour[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]School of Biomedical and Allied Health Science, University of Ghana, Accra, Ghana

Iodine is a micronutrient essential in the production of thyroid hormones for normal neurodevelopment. Based on iodine nutrition global data, nearly two billion (28%) of the world's population, including more than 321 million Africans (39%), are in danger of inadequate iodine intake. The WHO estimates that 60% of pregnant women worldwide do not meet the required intake. Current studies have associated iodine deficiency during pregnancy with a wide range of disorders; stillbirth, spontaneous abortions, hearing defects in infants, and cretinism. The aim of the study was to determine the iodine level and dietary habits in pregnant women. This cross-sectional study was performed among women attending antenatal clinics at Pentecost Hospital, Madina (PHM) in the Greater Accra Region. Dietary information related to iodine was obtained by using a food frequency questionnaire (FFQ). Urine iodine concentration (UIC) was performed on freshly collected urine samples, using the Sandell-Kolthoff reaction method with ammonium persulfate as the digesting agent. Results obtained showed that 50.6% (80/158) of participants had urine iodine levels below the WHO optimum range. Week of gestation had a positive association with the iodine levels in pregnant women. Regarding dietary habits, oats, yogurt, salted fish, and meat intake were significantly associated with urine iodine levels (r ranging from 0.1 - 0.2, p<0.05 in all cases). The study highlights the need for greater advocacy for pregnant women to take in iodine-rich sources of food in order to avoid possible iodine deficiency disorders in themselves and their unborn children.

5113

EFFECT OF PARTICIPANTS AGE AND OCCUPATION ON PERCEIVED SAFETY OF COVID-19 VACCINE AND PARTICIPANTS WILLINGNESS TO BE VACCINATED WITH COVID-19 VACCINE IN GHANA

Barbara Botwe[1], Alexander Kwarteng[2]

[1]Akenten Appiah-Menka University of Skills Training and Entrepreneurial Development, Kumasi, Ghana, [2]Kwame Nkrumah University Of Science And Technology, Kumasi, Ghana

The COVID-19 pandemic, declared a global health emergency by the World Health Organization in 2020, had a severe impact on the Ghanaian economy and caused harm to human life globally. This study aimed to provide evidence on the role of age and occupation in determining perceived safety and safety-related information regarding COVID-19 vaccines. The study examined the effect of age on participants' perceived safety of the COVID-19 vaccine, as well as the effect of occupation on their perceived safety and safety-related information. A cross-sectional survey was conducted, randomly sampling 2,000 participants, representing a 70% response rate. The study's results showed that the perceived safety of the COVID-19 vaccine was independent of the participants' occupation (X2=18.14, p-value =0.059). Additionally, the participants' willingness to be vaccinated was independent of their occupation (X2=1.86, p-value =0.86). Finally, the study found that participants willingness to be vaccinated was independent on the age categorization of the participants who participated in the survey. The study concluded that participants perception of the covid-19 vaccine safety was not influenced by the type of occupation and the age categorization of the participants.

5114

EVALUATION OF THE CLINICAL TRIAL OPERATION TRAINING CONDUCTED BY CENTER FOR INNOVATIVE DRUG DEVELOPMENT AND CLINICAL TRIALS FOR AFRICA

Eyasu Makonnen Eshetu

Addis Ababa University, Addis Ababa, Ethiopia

The number of clinical trials conducted in low and middle income countries (LMICs) is not satisfactory. Their quality is also questionable. This might be attributed to shortage of qualified personnel. Competency-based training for trial staff is required to build their capability. To this effect, CDT-Africa has conducted clinical trial operation (ClinOps) training in collaboration with course partners. As alignment of course contents to the local priorities of LMICs is critical for the success of clinical trial training, local tutors who were cognizant of the most common problems faced while conducting clinical trials in LMICs were involved. The training program activities were jointly planned with product development partners. A competency framework with andragogic innovations, jointly set by the Tropical Diseases Research program and The Global Health Network, was used in developing the curriculum. The training used Moodle Learning Management System as its platform for uploading VoiceThread links, learning materials, tasks, forum discussions and other assignments for access to trainees. This paper addresses impact of the training on trainees' confidence in conducting GCP compliant trials. We carried out a survey and used four core competencies: trainees' confidence in i) conducting, ii) managing, iii) designing & maintaining quality system and iv) effectively closing out & reporting results of clinical trials to evaluate the training outcome. Data taken from 69 trainees who took part in both the pre and post training survey were analyzed. Most of the respondents were trial site coordinators. Repeated measure t-test was carried out on four pair of scores in the four core competencies to see the presence of statistically significant difference in the scores of the respondents in confidence measured at the two different times. The test indicated that their confidence in all the four core competencies significantly increased after training compared to what they had before. In conclusion, the ClinOps training helped trainees acquire relevant knowledge & develop confidence in conducting GCP compliant clinical trials.

5115

THE RELATIONSHIP BETWEEN DISTANCE TO PRIMARY HEALTH CENTER, CHILD MORTALITY, AND AZITHROMYCIN MASS DISTRIBUTION IN NIGER: A SUBGROUP ANALYSIS OF THE MORDOR I CLUSTER-RANDOMIZED TRIAL

Ahmed M. Arzika[1], Dennis Chao[2], Elisabeth Root[2], Anu Mishra[2], Abdou Amza[3], Ramatou Maliki[1], Karamba Alio[1], Diallo Beidi[1], Elodie Lebas[4], Ben F. Arnold[4], Jeremy D. Keenan[4], Thomas M. Lietman[4], Kieran S. O'Brien[4]

[1]Centre de Recherche et Interventions en Sante Publique, Niamey, Niger, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States, [3]Programme Nationale de Sante Oculaire, Niamey, Niger, [4]UCSF Proctor Foundation, San Francisco, CA, United States

Increased distance to health centers has been associated with increased child mortality in several West African settings. Azithromycin mass drug

administration (MDA) has been found to reduce child mortality. Identifying subgroups where mortality reductions are the largest could help target future programs. Our objective was to assess whether distance to primary health center modified the effectiveness of azithromycin MDA to reduce mortality in a subgroup analysis of the MORDOR I-Niger trial. This cluster-randomized trial enrolled 594 rural and peri-urban communities in Dosso and randomized them to biannual oral azithromycin or placebo to children 1-59 months old for 2 years. A population-based census was conducted every 6 months to collect location data, administer treatment, and collect data on mortality and person-time at risk in the target group. Distance from each community center to the nearest primary health center was calculated. Negative binomial regression was used to determine whether the community-level effect of azithromycin on mortality differed by distance to primary health center, controlling for average community age. Median distance from community center to the nearest primary health center was 5 kilometers (km; interquartile range 3.2 to 7.1). For each kilometer increase in distance in the placebo arm, mortality increased by 5% (adjusted incidence rate ratio [aIRR] 1.05, 95% CI 1.03 to 1.07, P-value < 0.001). The effect of azithromycin MDA on mortality was found to vary significantly by distance (P-value for interaction term = 0.02). Overall, we found no difference in mortality by arm in communities closest to primary health centers and an increasing reduction in mortality in the azithromycin arm compared to placebo as distance increased. For example, the reduction in mortality with azithromycin vs placebo was 0% at 0 km from the health center (95% CI -19% to 17%), 4% at 1 km (95% CI -12% to 17%), 16% at 5 km (95 CI 7% to 23%), 28% at 10 km (95% CI 17% to 38%), and 39% at 15 km (20% to 54%). Children who live farthest from existing healthcare facilities may benefit the most from azithromycin MDA.

5116

SPILLOVER EFFECT OF AZITHROMYCIN MASS DRUG ADMINISTRATION ON ANTIMICROBIAL RESISTANCE IN NIGER

Brittany Peterson[1], Ahmed Arzika[2], Ramatou Maliki[2], Amza Abdou[3], Eric Houpt[4], Tom Lietman[1], Kieran O'Brien[1], Jeremy Keenan[1], Jie Liu[5]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Centre de Recherche et Interventions en Santé Publique, Niamey, Niger, [3]Programme Nationale de Santé Oculaire, Niamey, Niger, [4]University of Virginia, Charlottesville, VA, United States, [5]Qingdao University, Qingdao, China

MORDOR was a cluster-randomized mass drug administration (MDA) trial that compared child mortality in communities receiving two years of biannual azithromycin versus placebo. Azithromycin MDA has been shown to increase antimicrobial resistance (AMR) in the target 1-59-month age group. Given the community-based nature of this intervention, AMR may spill over into non-target populations as well. To better characterize the full population-level impact of azithromycin MDA on AMR, this study aimed to evaluate the presence of AMR spillovers in children 7-12 years of age not targeted for MDA. Thirty communities in the MORDOR morbidity trial were randomized to biannual azithromycin or placebo to children 1-59 months old. After 2 years of distributions, nasopharyngeal swabs were collected from a random sample of up to 40 children 7-12 years of age from all communities. Genetic determinants of resistance to macrolides, beta-lactams, tetracyclines, and fluoroquinolones were assessed at the individual level using TaqMan Array card. The presence of resistance determinants for each class was compared by arm using generalized estimating equations to account for clustering by community. Nasopharyngeal swabs were collected from a total of 1,103 children 7-12 years old. Compared to placebo communities, those in azithromycin communities had 1.34 times the odds of macrolide resistance (95% CI: 0.82 - 2.20), 1.06 times the odds of beta-lactam resistance (95% CI: 0.71 - 1.57), 0.99 times the odds of tetracycline resistance (95% CI: 0.45 - 2.20), and 0.45 times the odds of fluoroquinolone resistance (95% CI: 0.20 - 1.01). These findings suggest that there may be an increase in macrolide resistance in untreated children in communities receiving azithromycin versus placebo, although the MORDOR trial was not powered to detect this difference. More research is warranted to further our understanding of such spillover effects as a result of azithromycin distribution in MDA programs.

5117

TAKING BLOOD FROM CHILDREN FOR RESEARCH PURPOSES - WHAT DO PEOPLE THINK ABOUT IT? A QUALITATIVE STUDY TO EXPLORE THEFACILITATORS AND BARRIERS FROM A CLINICAL TRIAL CONDUCTED IN LALITPUR, NEPAL

Ashata Dahal

Oxford University Clinical Research Unit And University Of Oxford, Patan, Nepal

Clinical trials are a critical part of evidence-based medicine and blood sample collection is its important component. However, refusal of consent for blood draw is a common challenge associated with it. Literature exploring the perceptions of people regarding blood draw is scarce. We are conducting a qualitative research as a part of a large randomised controlled trial for a typhoid conjugate vaccine in children from Nepal. For the qualitative aspect of the trial, we are seeking to identify the motivators and barriers for blood draw from children for clinical research purposes. We are conducting in-depth interviews (IDIs) with the parents of children less than 18 years and the participants of the vaccine study who are now 18 years or older. There are around 17 study clinics in the community and a tertiary hospital where people with fever can come for check-up and are asked for blood draw if they meet the study fever criteria. So far, 16 in-depth interviews (IDIs) have been conducted with the participants who have consented and denied for blood draw for research purposes. IDI will be conducted until data saturation. We found that most of the participants did not understand the purpose of drawing blood for research purposes and their major motivation to provide consent was the trust towards the health professionals. The perception that it will be painful to draw blood from a sick child, making them weaker, is the major factor for blood draw denial. We also found that people had no problem in drawing out blood from sick adults but they felt the volume of blood drawn from a sick child was excessive, hence their hesitation. We have not heard any social belief related to blood draw so far that could lead towards denial of blood draw. To facilitate research that entails blood draw, health professionals and especially medical officers or nurses should continue to explain in detail about the purpose of blood draw for research purposes. Pain relief ointment can also be considered prior to blood draw. Additionally, engagement activities can be conducted to address the concern of volume and health consequences of blood draw thus improving consent procedures in future studies.

5118

EPIDEMIOLOGY OF LEPROSY IDENTIFIED THROUGH ACTIVE CASE DETECTION IN SIX DISTRICTS OF NEPAL

Ram Kumar Mahato

Epidemiology and Disease Control Division, Kathmandu, Nepal

Pediatric cases and grade-2 disabilities (G2D) indicate recent transmission and late diagnosis respectively, which necessitate active and early case detection. This operational research was performed to identify approaches best suited for early case detection, determine community-based leprosy epidemiology, and identify hidden leprosy cases early and respond with prompt treatment. Active case detection was performed by: door-to-door visits among vulnerable populations (n=26,469), contact examination and tracing (n=7,608) and screening prison populations (n=4,428) in Siraha, Bardiya, Rautahat, Banke, Lalitpur and Kathmandu districts of Nepal. New case detection rates were highest for contact tracing (250), followed by house-to-house visits (102) and prison screening (45) per 100,000 population screened. However, cost per case identified was cheapest for house-to-house visits (Nepalese rupee (NPR) 76,500/case), then contact tracing (NPR90,286/case) and prison screening (NPR298,300/case). House-to-house and contact tracing case paucibacillary/multibacillary

(PB:MB) ratios were 59:41 and 68:32; female/male ratios 63:37 and 57:43; pediatric cases 11% in both approaches; and G2D 11% and 5% respectively. Developing leprosy was similar among household and neighbor contacts (Odds ratios (OR)=1.4, 95% confidence interval (CI), 0.24-5.85) and for contacts of MB versus PB cases (OR=0.7, 0.26-2.0). Attack rates were similar among household contacts of MB cases (0.32%, 0.07-0.94%) and PB cases (0.13%, 0.03-0.73) and neighbor contacts of MB cases (0.23%, 0.1-0.46) and PB cases (0.48%, 0.19-0.98). BCG vaccination with scar presence had a significant protective effect against leprosy (OR=0.42, 0.22-0.81). In conclusion, the most effective case identification approach here is contact tracing, followed by house-to-house visits in vulnerable populations and screening in prisons, though house-to-house visits were cheaper. The findings suggest hidden cases, recent transmission, and late diagnosis in the community exist and highlight the importance of early case detection.

5119

ADDRESSING PROVIDERS' DISTRUST OF MALARIA RAPID DIAGNOSTIC TESTS THROUGH PEER-TO-PEER ENGAGEMENT

Eno'bong Idiong[1], Angela Acosta[2], Bolatito Aiyenigba[1], Jeroh Oghenevwogaga[1], Chika Aboh[1], Nnenna Ogbulafor[3], Foyeke Oyedokun-Adebagbo[4], Ian Tweedie[1]

[1]Breakthrough ACTION Project, Johns Hopkins Center for Communication Programs, Abuja, Nigeria, [2]Breakthrough ACTION Project, Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [3]National Malaria Elimination Program, Abuja, Nigeria, [4]U.S. President's Malaria Initiative, USAID, Abuja, Nigeria

In Nigeria, 40% of public sector providers prescribe antimalarials without parasitological confirmation. Studies show that provider norms and misconceptions influence adherence to fever case management (FCM) guidelines. From January 2019 to December 2022, Breakthrough ACTION-Nigeria convened quarterly small group discussions with Officers-in-Charge (OICs) from 417 primary health facilities in 5 states to discuss diagnostic norms and misconceptions, exchange experiences, review data, and develop action plans to improve FCM. Selected facilities are designated by the government to provide a minimum package of services within each ward. Before each session, 417 OICs completed self-administered surveys about their own knowledge and attitudes toward FCM. After sessions, OICs conducted similar "step-down" meetings with 712 facility staff. District Health Information System (DHIS) data was analyzed to examine trends in testing and adherence. The testing rate rose from 85% to 94% between Dec 2018 and Dec 2022. The proportion of test-positive cases who received artemisinin-combination therapy (ACT) increased from 82% to over 98%. While the DHIS does not capture test-negative results, clinical diagnosis (proportion of fever cases receiving ACTs without a malaria test) decreased from 20% to 0.8%. Though the number of fever cases seen decreased during the pandemic, testing and adherence rates did not. Average OIC knowledge and attitude scores rose from 44% in 2019 to 80% in 2022, and during meetings, OICs reported improved norms and attitudes toward malaria rapid diagnostic tests (RDTs) among staff. Scores improved after one session, but meeting discussions reflected lingering doubts such as concerns about RDT storage conditions prior to arrival at the facility that diminished with time. Results suggest that a sustained, peer learning approach may address entrenched concerns and contribute to improved FCM adherence. Future research should track attitudinal shifts among facility staff in addition to OICs, use control sites, and compare the peer-to-peer approach to other quality improvement initiatives.

5120

LIVED EXPERIENCES AND COPING STRATEGIES ADOPTED BY ADOLESCENTS IN THE MANAGEMENT OF ONCHOCERCIASIS IN A RESOURCE LIMITED SETTING OF GHANA

Sitsofe Gbogbo, Hubert Amu, Robert Dowou, Martin Ayanore

University of Health and Allied Sciences, Ho, Ghana

Onchocerciasis is a neglected tropical disease that continue to be a major contributor to disabling skin and eye conditions. Sub-Saharan Africa accounts for 99% of the total global prevalence of the disease, with about 37 million people infected and about 300, 000 permanently blind. This is a cross-sectional study adopting a phenomenological qualitative approach. We conducted in-depth interviews among 16 onchocerciasis adolescent patients between June 2022 – July 2022 in order to explore the lived experiences and coping approaches adopted by adolescents in the management of onchocerciasis. Data was analysed using Interpretative Phenomenological Analysis (IPA) with ATLAS.ti version 7.5.7, and results presented in themes and supported with quotes. Half (50.0%) of the adolescents interviewed were aged 15-17 years old; majority (62%) of them were still in school. Also, 25.0% of them had lived with the condition for over 10 years. The major initial symptoms experienced by adolescents were blurred vision, ball-like moving nodules in the body, and frequent fatigue. Majority of the participants reported that their experience with hospital-based management of their condition in terms of quality of treatment and care they received from the health professionals. Majority of participants preferred hospital management as compared to home-based treatment. The main coping strategies adopted by participants in dealing with their conditions were religious in nature expressed through faith and belief in God by prayer; and recreation by playing football and watching movies. The findings revealed that most participants delayed in seeking healthcare, and only did so after complications had developed. The delay we believe could be due to a lack of access to appropriate information and education about onchocerciasis. Religion and recreation were the main strategies adopted by participants in coping with their conditions. This points to the need for health authorities and policymakers to intensify education and communication campaigns on NTDs in general and onchocerciasis in particular in the last miles settings of developing countries like Ghana.

5121

SPATIAL INEQUALITY IN CHILDHOOD IMMUNIZATION COVERAGE IN NIGERIA: A GEOSTATISTICAL APPROACH

Ezra Gayawan[1], Osafu Egbon[2], Olamide Orunmoluyi[1]

[1]Federal University of Technology, Akure, Nigeria, [2]University of Sao Paulo, Sao Carlos, Brazil

Routine vaccination for children and mass immunization campaigns are key global public health strategies for reducing morbidity and mortality from infectious diseases. The Expanded Program on Immunization (EPI) aimed at providing routine immunization to all children less than two years of age in Nigeria. Though initial progress towards attaining universal coverage was documented, structural and organizational challenges soon constitute barriers to the ambitious targets of the EPI strategy. Estimates from the 2018 Nigeria Demographic and Health Survey (NDHS) indicate that only 37% of children aged 12-23 months received all basic vaccinations while 21% received all age-appropriate vaccinations. Combining data from 2008, 2013, and 2018 NDHS with ancillary data sources, we adopt a model-based geostatistics approach to characterize and quantify spatial variations in full immunization coverage (defined as children aged 12-23 months who have received one dose of BCG vaccine, three doses of DPT-containing vaccine, three doses of oral polio vaccine, and one dose of measles vaccine) as explained by factors such as women disempowerment, intimate partner violence (IPV), and other child's and mother's characteristics. We also considered the influence of travel time to nearest health facility, fear over personal safety, and local population size on the spatial patterns of immunization coverage. Women disempowerment, IPV and travel time

are among the barriers to uptake of childhood vaccines, exacting varying influence at different locations in Nigeria. Locally tailored intervention would be effective in enhancing coverage in the country.

5122

UNDERSTANDING COVID-19 VACCINE HESITANCY IN THE JOHNSONVILLE, PEPPER WULU TOWN COMMUNITY LIBERIA: A QUALITATIVE STUDY

James Douglas Sinnatwah Jr.

University of Liberia School of Public Health, Monrovia, Liberia

The COVID-19 pandemic has had widespread morbidity and mortality, with nearly 6.2 million deaths globally. In Liberia, fewer cases and deaths have been reported than in other countries, but the limited healthcare resources in this low-income country makes the population vulnerable, in the event of more virulent variants. The COVID-19 is no exception. To protect against the COVID-19 virus, vaccines are being distributed; yet coverage targets have not been met. The objectives of this research were to understand COVID-19 vaccine hesitancy among people in the Johnsonville Pepper Wulu Town community, and to gather community feedback on what can be done to encourage the uptake of COVID-19 vaccines. A qualitative study was conducted with purposive sampling identifying 12 community members who were expected to have knowledge and understanding about the COVID-19 vaccine. All participants were aged 18 years or older and had resided in the community for not less than six (6) months. Audio recordings of in-depth interviews were transcribed and manually coded; thematic analysis was undertaken. From the study conducted, three themes were generated to group participants' statements into category which better explained what they know about the COVID-19 vaccine. Out of the 12 participants interviewed, 10 said they have not gotten any dose of the COVID-19 vaccine and were not willing to take the vaccine due to reasons like fear to die in two years after taking the vaccine and lack of trust in Government. Eight indicated that they are not prepared to recommend the vaccine to their child/children, friends or relatives. The results of the study showed that COVID-19 vaccine hesitancy exists in the community and it comes from issues such as misinformation, lack of information, and/or mistrust. Mobilization through prominent individuals and Community based-Organizations along with building emotional support, and increased knowledge to overcome misinformation would help to alleviate the myths of death, and liaising with stakeholders to address concerns around trust could help improve uptake.

5123

AN ETHNOBOTANICAL STUDY ON MEDICINAL PLANTS USED AS ANTIDOTES FOR SNAKEBITE AND AS SNAKE REPELLENTS IN THE HAUTS BASSINS AND SOUTHWEST REGIONS OF BURKINA FASO

Rabila Bamogo[1], Achille Sindimbasba Nikièma[1], Mamounata Belem[2], Youssouph Diatta[3], Roch Kounbobr Dabiré[1]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Université de Joseph KI-ZERBO, Ouagadougou, Burkina Faso, [3]Université Cheikh Anta Diop, IFAN, Dakar, Senegal

Ophidian envenomation is a public health problem in the tropics and subtropics. Expensivecost of antivenoms forces most of the population to resort to medicinal plants as a first-linetreatment. The use of plant extracts for therapeutic purposes is a common practice intraditional African medicine. The present study aimed to contribute to a better knowledge of medicinal plants used in the treatment of snakebite envenomations and as a snake repellent inthe Hauts-Bassins and Southwest regions of Burkina Faso.In the province of Houet and the South West region, ethnobotanical information was collectedduring six months of the year 2022 from 117 people (traditional health practitioners andherbalists) using a questionnaire. Knowledge was assessed quantitatively using relativecitation frequency. A total of 31 plant families divided into 58 species have been identified by both traditionalpractitioners and herbalists. The distribution of these species by family showed thatPolygalaceae (28.2%), Annonaceae (14.52%), Fabaceae (13.67%) followed by Ebenaceae(3.41%) and Apocynaceae (3.41%) were the most mentioned. Roots were mostly used,68.96% (40/58) in the preparation of remedies. The majority of traditional healers were male(84.61%, 99/117). More than 80% (94/117) of respondents were not literate. Almost all of therespondents, 90% (105/117), had knowledge from their ancestry.The surveys made it possible to inventory a diversity of medicinal species and to collect asmuch information as possible concerning local therapeutic or repellent uses against snakes. Extensive pharmacological and toxicological studies need to be conducted for the reportedmedicinal plants to contribute to the well-being of local communities in tropical andsubtropical regions.

5124

MIXED EFFECTS MODELS IN THE ANALYSIS OF EPSTEIN BARR VIRUS SEROLOGICAL RESPONSES IN CHILDREN FROM CHULAIMBO WESTERN KENYA

Onditi Ian Arao[1], Ariera Bonface[1], Koech Emmily[1], Waomba Kevin[1], Stella Chumbe[1], Jackson Conner[2], Samayoa-Reyes Gabriela[2], Katherine R. Sabourin[2], Sidney Ogolla[1], Rosemary Rochford[2]

[1]Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, KISUMU, Kenya, [2]University of Colorado, Anschutz Medical Campus, Denver, CO, USA, Denver, CO, United States

In malaria-endemic regions, infants acquire Epstein Barr virus (EBV) as early as 6-months of age, resulting in poor viral control, which may contribute to endemic Burkitt's lymphoma development. Maternal malaria infection during pregnancy impairs vertical transfer of EBV specific antibodies. The impact of this impairment on the subsequent decay rate of maternally derived anti-EBV specific antibodies in infants remains to be determined. There exist two preferred classes of mixed effects models for analysis of longitudinally collected data; linear (LMMs) and nonlinear NLMMs mixed effects models. Whether LMMs perform sufficiently in scenarios suitable for NLMMs remains unclear. A total of 66 infants from Western Kenya, born to HIV-negative women, with or without malaria during pregnancy were enrolled and followed up from birth through 24 weeks of age. We assessed the performance of mixed effects models in the analysis of EBV serological responses comparing infants born to women with and without malaria infection during pregnancy (MEU and MUU respectively). The levels of anti-VCA and anti-EBNA1 IgG against EBV infection in cord (neonatal) and infant blood samples were quantified using multiplex bead-based assay and analyzed using LMM and NLMM. To evaluate model performance, Pearson correlation test was used to analyze observed versus predicted antibody levels. Decay rates of anti-VCA IgG between MEU and MUU did not differ significantly (P = 0.45). However, the decay rates of anti-EBNA1 IgG were significantly faster in the MUU group compared to MEU (P = 0.03) with a decrease rate of 0.26 and 0.14 per month, respectively. Correlations between observed versus predicted VCA and EBNA1 IgG levels demonstrated the competent performance of LMM in fitting both VCA and EBNA1 IgG responses (r: 0.89 and 0.71, respectively) compared to NLMM (r: 0.95 and 0.89). These findings suggest that in utero malaria exposure does not impact decay rates of maternally derived anti-VCA IgG and EBNA1 IgG. Moreover, both LMM and NLMM performed well with NLMM being slightly more robust in the analysis of EBV serological responses in infants over time.

5125

MOLECULAR CHARACTERIZATION OF THE RHESUS D (RHD) GENE IN BLOOD DONORS WITH THE DEL PHENOTYPE AT THE NATIONAL BLOOD TRANSFUSION CENTER (CNTS) OF BAMAKO, MALI

Ramatoulaye Diallo[1], Dramane Diallo[2], Amadou Kone[2], Tenin Aminatou Coulibaly[2], Alhassane BA[1], Moussa Cisse[1], Boubacar Maiga[3]

[1]Centre National de Transfusion Sanguine, Bamako, Mali, [2]University of Clinical Research Center, Bamako, Mali, [3]Université des Sciences des Techniques et des Technologies de Bamako, Bamako, Mali

The Rh Del phenotype, expressed very weakly on the surface of red blood cells, can only be detected by adsorption/elution. The RhD1227 allele is the most common Rh Del with a grossly intact RhD gene. In Mali, there is very little information on the prevalence of the Del phenotype. The objective of this study was to perform a molecular characterization of the DEL phenotype in blood donors. After confirmation of Rh Del by adsorption/elution on donor blood bags at the CNTS, DNA from the samples was isolated with the QIAamp blood DNA mini kit and amplified by PCR using primers specific to the RhD gene and the RhD1227A allele. Amplicons were visualized on a 1% agarose gel under UV light. 365 serologically negative RhD donors were included in this study. The majority was male with 90.4%. The age range [26-39] represented 52.9% and the mean age was 32.54±33.53 years. The Ccee phenotype accounted for 72.72%. Blood group O was the most represented with 38.6%. The Rh Del phenotype was positive in 7.1% (26/365). All ten exons of the RhD gene were amplified in 69.23% of the Rh Del positives and the RhD 1227A allele was present in the samples. Our study showed the presence of the intact Rh D gene in all samples with the presence of the Rh Del mutation. However, we observed other non-specific amplifications that would be interesting to characterize by sequencing.

5126

ACADEMIC ACHIEVEMENT AMONG CHILDREN WITH SICKLE CELL ANAEMIA IN UGANDA

Shubaya K. Naggayi[1], Paul Bangirana[2], Robert O. Opoka[1], Deogratias Munube[1], Phillip Kasirye[1], Ezekiel Mupere[1], Betty Nyangoma[3], Annet Birabwa[4], Grace Nambatya[1], Maxencia Kabatabaazi[1], Ann Jacqueline Nakitende[2], Dennis Kalibbala[5], John Ssenkusu[6], Chandy C. John[7], Nancy S. Green[8], Richard Idro[1]

[1]Department of Paediatrics and Child Health, Makerere University, College of Health Sciences, Kampala, Uganda, [2]Department of Psychiatry, Makerere University, College of Health Sciences, Kampala, Uganda, [3]Makerere University, Johns Hopkins University, Research Collaboration, Kampala, Uganda, [4]Department of Mental Health and Community Psychology, Makerere University College of Humanities and Social Sciences, Kampala, Uganda, [5]Global Health Uganda, Kampala, Uganda, [6]Department of Epidemiology and Biostatistics, Makerere University College of Health Sciences, Kampala, Uganda, [7]Department of Pediatrics, Indiana University, Indiana, IN, United States, [8]Department of Pediatrics, Division of Pediatric Hematology, Oncology and Stem Cell Transplantation, Columbia University Irving Medical Center, New York, NY, United States

Academic achievement among children of school age is crucial in attainment of optimal learning goals. Children with Sickle Cell Anaemia (SCA) are prone to cognitive deterioration which might impact their academic achievement. Limited data exists on the academic achievement of school-going children with SCA in Uganda. We conducted a cross-sectional study among children with SCA aged 6-12 years attending the Sickle Cell Clinic at Mulago National Referral Hospital in 2019. Controls were siblings/immediate relatives without SCA. The Wide Range Achievement Test-4 (WRAT-4), was used to measure cross-sectional spelling, reading, math and sentence comprehension. Age-appropriate items were administered for each age group. The WRAT-4 raw scores were converted to z-scores based on age and gender. T-tests were used to compare the z-scores of the controls with the cases. Linear regressions adjusting for social economic status, home stimulation and environment were used to compare the association between SCA and academic achievement. A p-value <0.05 was considered significant. A total of 68 cases (30 females, 44.1%) and 69 controls (37 females, 53.6%) were enrolled. Mean age was 9.0±2.0 years for both cases and controls. Overall, cases performed poorer than controls (Mean difference: -0.25, 95% CI: -0.02-0.53, p-value=0.03). Results for each subtest demonstrated that cases performed poorer than controls in math, with z-scores of -0.36 vs. 0.02 (p-value= 0.002) and spelling, with z-scores -0.31 vs. 0.03 (p-value=0.02). Cases and controls did not significantly differ in reading, with both groups scoring below the test's mean z-score. In contrast, in sentence comprehension, both cases and controls scored similarly and performed above the mean z-score. No significant differences were found between cases and controls for mother's education, social economic status or home environment. Children with SCA in Uganda have poorer performance in math and spelling compared to their healthy siblings/peers. Additional education support in maths and spelling may be considered to reduce these differences in academic achievement.

5127

HEALTH DETERMINANTS AMONG INDIVIDUALS WORKING AT AMAZONIAN GOLD MINING SITES: A MULTICENTRIC CROSS-SECTIONAL SURVEY

Maylis Douine[1], Yann Lambert[1], Lorraine Plessis[1], Irene Jimeno[1], Teddy Bardon[1], Carlotta Carboni[1], Antoine Adenis[1], Stephen Vreden[2], Martha Suarez-Mutis[3], Alice Sanna[1]

[1]Centre d'Investigation Clinique Antilles-Guyane Inserm 1424, Cayenne, French Guiana, [2]Foundation for Scientific Research, Paramaribo, Suriname, [3]Foundation Oswaldo Cruz, Rio de Janeiro, Brazil

Many determinants, such as the political, social and economic environment, the physical environment, individual characteristics and behaviors, or access to care, combine to impact the health of individuals and communities. In French Guiana (FG), the people working on the illegal gold mines spread in the heart of the tropical forest are a particularly vulnerable population which lives under the radar of the health system. This study aimed to better understand the individual and collective determinants of health in this specific population. This international multicenter cross-sectional survey included people working on the illegal FG gold mines at the crossing points located at both borders with Suriname and Brazil. After collecting written informed consent, a structured questionnaire was administered. From September to December 2022, 539 gold miners were included in the study. They represented a migrant population (95.8% from Brazil) with little education and low income. They did not have access to drinking water (95.4%) or latrines (95.4%). They were exposed to mercury by inhalation (58.8%) or ingestion (80.5%). They were in close contact with wildlife by hunting (23.8%), eating bushmeat (65.1%) or being bitten by animals or insects (66.8% and 98.3%). Accidents were frequent (13.5%) and access to health care was difficult, mainly because of the distance from health structures. While 11.9% suffered from chronic diseases, treatment interruptions were frequent (26.6%). Women seemed to be less bitten by animals or exposed to mercury but felt less healthy than men. This study shows that the population of gold miners in FG combines different health determinants leading to poor health. Their illegal activity poses ecological, economic and societal problems. But for ethical as well as public health reasons, health promotion actions must be discussed at different levels: individual, environmental or systemic. However, these approaches are worthless without a global societal approach. Public policies around gold mining should take into consideration the individual and collective health dimensions.

DXCONNECT TEST DIRECTORIES: GLOBAL IMPACT THROUGH ACCESSIBLE DATA ON DIAGNOSTIC ASSAYS

Victoria O. Aroworade, Anna Mantsoki, Stefano Ongarello, Devy Emperador, Sarah Nogaro, Sophie Crettaz, Dounia Cherkaoui, Daniel G. Bausch, Sarah-Jane Loveday, Kavi M. Ramjeet
FIND, Geneva, Switzerland

A fundamental lesson from the COVID-19 pandemic is that dissemination of reliable, evidence-based information is essential to confront novel pathogens by enabling robust and reassuring decision-making. The sudden emergence of a vast number of diagnostic tests, without clear guidance on quality, use cases, or routes to procurement, contributed to global instability and panic. FIND established an open-access, centralized directory of COVID-19 diagnostics to track availability, regulatory status and performance of molecular and rapid tests (antibody and antigen). Today, the COVID-19 test directory contains data on 2124 tests, to support countries and other stakeholders with ongoing pandemic response and containment strategies, as well as to bring transparency to the R&D landscape. Test data are gathered via various workstreams, including proactive scouting, review of scientific publications and regulatory databases, and outreach to manufacturers to request direct submission of test data via online forms. Variables collected include product/technology features, performance characteristics, and regulatory status. Interactive dashboards and curated tables are publicly available and updated in real time on the FIND website. In response to positive feedback from stakeholders, new directories were quickly set up in response to the mpox and ebolavirus outbreaks of 2022, which currently contain 119 and 70 tests, respectively. Further, a test directory dedicated to neglected tropical diseases has been set up to bring transparency to the diagnostic pipeline and maximize the impact of scarce resources in that area. Looking to the future, the test directories are being harmonized and consolidated into one single platform, which will facilitate further expansion of test information on other diseases of outbreak potential, vaccine-preventable diseases, tuberculosis, and antimicrobial drug-resistance. By supplying a bird's eye view of the diagnostic landscape, this suite of test directories provides actionable insights that can improve access to diagnostics and global health.

5129

PSYCHOSOCIAL PROBLEMS AFFECTING GIRLS IN SELECTED SCHOOLS IN POST CONFLICT LIBERIA

Juah T Karpeh
Cuttington University, Gbarnga, Liberia

In post conflict Liberia, psycho-social problems are those that affect the mental psyche of the individual and therefore affects an individual productive capacity. Girls in secondary schools especially in developing countries endue the burden of psycho-social problems caused by parents, school policy makers; and practitioners recognizes that social, emotional, physical health and other major burden to learning must be addressed if schools are to function satisfactorily and students are to learn and perform effectively. The objectives of the study includes: identify the impact of psychosocial problems affecting girls in secondary schools in post conflict Liberia; identify the challenges of girls in secondary schools in post conflict Liberia; identify the perception of psychosocial problems of girls in secondary schools in post conflict Liberia; identify the problems of poor performance of girls in secondary school; and to identify appropriate suggestions or recommendations that will enhance peaceful co-existence between girls in secondary schools in post conflict Liberia. A cross- sectional mixed method design was used. The sampling method for the research was a random sampling technique. Data was analyzed using Microsoft Office Excel, Frequency tables and SPSS for the quantitative, FGDs and Nvivo was used for the qualitative data. The findings of the study revealed that: the impact of psycho-social problems on girls in secondary schools in post conflict Liberia are: 50% fair, 25% good and 25% bad; the challenges for girls with psycho-social problems in secondary schools in post conflict Liberia are: low average performance (25%), good performance (15%) and poor performance (20%) whereas, the effect of psycho-social problems on girls in secondary schools in post conflict Liberia were found to be: low concentrations and dizziness towards school work. To critically deal with psycho-social problems faced by girls in secondary schools in post conflict Liberia, rehabilitate them by providing good learning atmosphere.

5130

ANTHROPOMETRIC DIFFERENCES IN COMMUNITY- VERSUS CLINIC-RECRUITED INFANTS PARTICIPATING IN A TRIAL OF AZITHROMYCIN FOR PREVENTION OF INFANT MORTALITY

Mamadou Ouattara[1], Ali Sie[1], Mamadou Bountogo[1], Valentin Boudo[1], Elodie Lebas[2], Huiyu Hu[2], Benjamin F. Arnold[2], Thomas M. Lietman[2], **Catherine Oldenburg**[2]
[1]Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, [2]University of California, San Francisco, San Francisco, CA, United States

Community-based distribution of azithromycin to children aged 1-59 months of age has been shown to reduce all-cause childhood mortality. However, studies of clinic-based distribution of azithromycin have generally not shown a difference between children receiving azithromycin and placebo. Clinic-based recruitment strategies may miss the most vulnerable children. Here, we evaluated baseline anthropometric measures in a trial of azithromycin for prevention of infant mortality that recruited infants both directly in the community and in clinics. Infants aged 5-12 weeks were recruited in Nouna District, Burkina Faso via vaccine outreach visits directly in the community or during vaccination visits in primary healthcare facilities. We classified infants as "community-recruited" if they were recruited via these outreach visits, regardless of whether formal enrollment in the trial occurred in the community or clinic. Clinic-recruited infants were recruited and enrolled in the trial during routine EPI vaccination visits. Height, weight, and mid-upper arm circumference measurements were collected at the time of enrollment in the trial. We compared underweight (weight-for-age Z-score < -2), wasting (weight-for-length Z-score < -2), and stunting (length-for-age Z-score < -2) in community versus clinic recruited infants. Among 32,859 infants enrolled in the trial, 65% were recruited in the community and 35% in clinics. Community-recruited infants were a median of 44 days (6.3 weeks) and clinic-recruited infants were a median of 50 days (7.1 weeks) of age. At baseline, 11.5% of infants were underweight, 9.5% were wasted, and 11.4% were stunted. In age- and sex-adjusted models, infants recruited in the community were more often underweight (odds ratio, OR, 1.25, 95% confidence interval, CI, 1.16 to 1.35) and wasted (OR 1.52, 95% CI 1.40 to 1.65). In conclusion, infants recruited in community settings had increased risk of signs of acute malnutrition (wasting and underweight), suggesting that clinic-based recruitment may miss children who would benefit most from interventions meant to improve child health.

5131

VACCINE MANAGEMENT PRACTICES AMONG HEALTHCARE WORKERS IN NORTHWESTERN STATE, NIGERIA: A COMPARATIVE STUDY

Adefisoye Oluwaseun Adewole[1], Ndadilnasiya Waziri[1], Idriss Bomoi[1], Simple Edwin[1], Babatunde Amoo[1], Gideon Ugbenyo[1], Rhoda Fadahunsi[1], Elizabeth Adedire[1], Aishat Usman[2], Belinda Uba[1], Patrick Nguku[1]
[1]African Field Epidemiology NETWORK, Abuja, Nigeria, [2]ECOWAS Regional Center for Surveillance and Disease Control, West African Health Organization, Abuja, Nigeria

Effective vaccine stock management is one of the criteria for a functional vaccine supply chain. It helps to maintain quality of vaccines, prevent stockouts and ensure continuous availability of vaccines. The study evaluated vaccine management practices among healthcare workers in equipped and non-equipped public health facilities in Jigawa State, Northwest Nigeria. Jigawa state has 765 functional health facilities providing routine immunization services. A cross sectional comparative study was conducted in November 2022 amongst healthcare workers with sample

size of 400 and multistage sampling technique for selection of respondents. A semi-structured questionnaire was used to obtain information on socio-demographic characteristics, knowledge and attitude on vaccine and cold chain management, and practices of healthcare workers on vaccine stock management. Data was analyzed using the Statistical Package for Social Sciences software version 23. Level of significance set at $p<0.05$. A total of 386 respondents participated in the study with a response rate of 97%. Respondents from equipped and non-equipped health facilities had mean age of 36.8 years ± 8.7 standard deviation and 35.8 years ± 7.1 standard deviation respectively. Two hundred and sixty-five (71.6%) and 105 (28.4%) worked at primary health care centres ($p<0.05$). Increased knowledge ($p>0.05$), years of working experience ($p<0.05$), positive attitude ($p<0.05$), and good practices ($p<0.05$) of vaccines and cold chain management was observed among respondents from equipped health facilities as compared to those from non-equipped health facilities. Barriers to effective vaccine handling include insufficient ice packs and cost of transporting vaccines to the health facility. Drivers of effective vaccine stock management are length of years working in health facilities, good knowledge, and practices on vaccine stock management as evident among healthcare workers from equipped health facilities. The findings from this study should be used to improve effective vaccine stock management at the state, LGA, and health facility levels.

5132

THE PREVALENCE OF UNDIAGNOSED HYPERTENSION AMONG RESIDENTS OF THE DUPORT ROAD COMMUNITY

Jeapolor Nutai Kolleh

E and J Medical Center, Ganta City, Liberia

Hypertension is an important public health and medical issue worldwide. It is the largest contributor to global burden of disease, accounting for 7% of global disability adjusted life years. Liberia is a low-income country and as such faces many challenges especially in the health sector. Most time people who visit the hospital for the first time poses serious complication of hypertension thereby placing extra burden on the already challenged healthcare services. Undiagnosed hypertension is a risk factor for mortality and morbidity among Liberians since there is no presenting symptoms, furthermore the idea is regular screening and hospital checkup is not common in Liberia. The study seeks to identify the proportion of older population living with undiagnosed hypertension. A cross sectional study conducted in the Duport Road Community in 2019 with 167 participants' age 30 years and above who has never been diagnosed with hypertension selected for the study. Participants answered a questionnaire through direct interviews and their blood pressures were measured using automated digital blood pressure machine. Individuals who had systolic blood pressure above 139mmHg and or diastolic blood pressure above 89mmHg had two subsequent measurement of their blood pressure. The results of the study revealed that 29% (n = 49) of the participants had Hypertension (systolic blood pressure >139 mmHg and or Diastolic blood pressure of >89mmHg). Furthermore, 70% (n=118) of the study population had not had a blood pressure check in the preceding 5 years or could not remember the last time they check their blood pressure. Out of the 49 participants who were hypertensive, 65% (n = 32) were 50 year old and above. Hypertension is significantly associated with increasing age, while the lack of regular screening regularly health care visit has attributed to the high prevalence of undiagnosed hypertension among the inhabitants of the Duport Road Community.

5133

INTEGRATED SKIN DISEASE TRAINING IN VANUATU: PEER-SUPPORTED CAPACITY BUILDING TRANSFORMING HEALTH WORKER CONFIDENCE

George Taleo[1], Thyna Orelly[2], Fasihah Taleo[3], Isis Umbelino-Walker[1], Alan Brooks[4], Anastasia Pantelias[1], Julie Jacobson[1]

[1]Bridges to Development, Vashon, WA, United States, [2]Ministry of Helath, Port Villa, Vanuatu, [3]World Health Organization, Port Villa, Vanuatu, [4]Bridges to Development, Geneva, Switzerland

Programs targeting Neglected Tropical Diseases (NTDs) are routinely implemented focused on individual diseases. The financial and opportunity costs of single disease activities are substantial, and, as a result, there has been a call to move towards integrated programs targeting multiple NTDs at once. An integral part of a successful NTD program is training health workers (HCWs) on the prevention, diagnosis, treatment, management, and reporting of NTDs in health facilities and communities. As part of a larger implementation project, the Vanuatu Ministry of Health developed and piloted an Integrated Skin Disease (ISD) training targeting yaws, scabies, and leprosy in three Vanuatu provinces between June 2021 and October 2022. The aim was to increase HCWs' confidence and competencies in diagnosing and managing the care of patients with skin diseases, including community low-up. Unlike typical training, which is often didactic and based largely on one-way information delivery from expert to trainee, ISD used principles of adult learning and took a unique participatory, scenario-based, and peer-learning approach. The training improved the capacity and confidence of 97 HCWs to identify, diagnose, treat, and report cases of skin NTDs. ISD introduced new tools and resources to support HCW in managing cases of skin NTDs and new systems to facilitate timely and accurate reporting to the MoH. For example, for scabies, we observed increased knowledge of 30% to diagnose, 32% to treat, and 37% to refer. Participants, supported by the MoH, developed a plan and have continued rolling out the novel training approach. ISD also improved channels of communication. It catalyzed the creation of a self-sustaining network to support continuous learning and peer support. The training methodology increased dialogue between the MoH NTD programs and health facilities, which (i) enriched the learning experience and (ii) highlighted gaps and needs of health clinics. The ISD showed that participatory, peer learning that builds on the direct experience and local contexts of health practitioners and volunteers can strengthen capacity and support local transformation.

5134

"I BELIEVE BECAUSE THE VACCINE IS NOT COMING TODAY" - AN EXPLORATION OF THE SOCIO-BEHAVIORAL FACTORS INFLUENCING CHILDHOOD VACCINATION UPTAKE IN URBAN POOR SETTLEMENTS IN NAIROBI, KENYA

Judy Gichuki, Ben Ngoye

Strathmore University, Nairobi, Kenya

Childhood vaccination uptake has been on the decline, with the World Health Organization estimating that approximately 25 million children missed out on one or more vaccination doses in 2021. Often, children residing in marginalized populations are at a higher risk of being unvaccinated. In Kenya, timely immunization coverage in urban poor settlements remains below 50%. Timely vaccination is crucial in maintaining population immunity against vaccine-preventable diseases (VPDs) and in preventing VPD outbreaks. Exploring context specific reasons for missed vaccinations facilitates the development of tailored interventions. This study aimed at exploring the behavioral and social factors that influence timely childhood vaccination uptake in the urban poor settlements of Nairobi, Kenya. Five focus group discussions (FGDs) were conducted with purposively sampled caregivers of children under five years of age residing in two urban slums in Nairobi. Each FGD involved face-to-face discussions with groups of seven to nine caregivers using an open-ended FGD guide. The development of the FGD guide was guided by the Theory of Planned Behavior. The FGDs were audio-recorded, translated and transcribed. Thematic framework

analysis was used to identify emerging themes and patterns. A total of 39 respondents participated in the FGDs. The median age for the participants was 29 years (range 20-52 years). Although vaccination was perceived to be beneficial and effective in preventing disease, uncertainties about the side effects of vaccination, lay theories and cultural beliefs negatively influenced vaccination uptake. The level of spousal support and lack of the mother's autonomy in vaccination decisions greatly influenced access to timely vaccination. There was inadequacy of vaccination information to facilitate caregiver decisions, with male participants expressing marginalization in vaccination messaging and processes. Community derived and context specific approaches such as tailored messaging need to be tested and applied to enhance timely childhood vaccination uptake in these marginalized populations.

5135

AVAILABILITY AND ACCESSIBILITY OF SUICIDE PREVENTION SERVICES: A GLOBAL INVESTIGATION

Gladson Vaghela[1], Randa Elsheikh[2], Nguyen Hai Nam[3], I-Chun Hung[4], Mohamed H. Khalil[5], Zeeshan Khan[6], Aashish Lamichhane[7], Abdelrahman Makram[8], Minh-Hang Nguyen[9], My Duc Thao Trieu[10], Nguyen Tien Huy[11]

Suicide is a major global public health issue, worlwide. Suicide prevention services, especially helplines, are crucial resources for individuals at risk of suicide, providing immediate crisis counselling, emotional support and information. However, the availability and accessibility of these services vary greatly across countries and regions, and the effectiveness of these services in reducing suicide rates is not well established. We conducted a global, cross-sectional survey of suicide helpline services. A comprehensive directory of helpline services was created by a team of local collaborators to estimate the number of suicide prevention services available in each country. "Find A Helpline," the largest suicide helpline resource, helped disseminate the survey to their network in over 100 countries. In areas with limited outreach, the questionnaire was directly distributed by local collaborators to increase participation. As of writing, we have collected 460 responses from suicide helplines in 104 countries. The results showed that most services (75.7%) were available nationwide, while 15.7% of services were functional at the state/province level, and 4.3% of services were available at the county/district level. Telephone-based services were the most common mode of service delivery (87.8%), with most services (77.6%) operational 24*7. However, 48.5% of the services reported a decrease in funding levels after the onset of the COVID-19 pandemic. Most helplines (82.4%) provided free services, while only 11.5% provided language translation services. Additionally, only 22.2% of the helplines provided annual booster/refresher training for their staff, and lack of funding and low pay for staff were reported as major challenges by many helplines. Youths were regarded as the most difficult groups to consult with. The findings can inform policymakers and stakeholders in developing strategies to improve the availability, quality, and sustainability of suicide helpline services worldwide. The difficulties of consulting with youths also emphasize the need for specialized training and services for this vulnerable group.

5136

COMPREHENSIBILITY OF THE EBL2007 CLINICAL TRIAL BY PARTICIPANTS FROM THEIR ENROLLMENT UP TO TWO YEARS OF FOLLOW UP

Trésor Zola Matuvanga[1], Ynke Larivière[2], Gwen Lemey[2], Joachim Mariën[2], Bernard Osangir[3], Patrick Mitashi[4], Hypolite Muhindo-Mavoko[1], Junior Matangila[1], Junior Matangila[1], Pierre Van Damme[2], Jean-Pierre Van gertruyden[2]

[1]University of Kinshasa, DRC/Kinshasa, Congo, Democratic Republic of the, [2]University of Antwerp, Antwerp, Belgium, [3]University of Kinshasa, Antwerp, Belgium, [4]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the

In Boende, Democratic Republic of Congo (DRC), an Ebola vaccine trial included health care providers and frontliners. A sub-study developed a true/false questionnaire to assess the understanding of trial consent among participants (Test of Understanding, TOU). One of the eligibility criteria for participation in the trial was the ability to successfully answer at least 9/10 questions of the TOU. This substudy assessed whether participants understanding of the consent/EBL2007 vaccine protocol evolved over years after signing consent in a trial that was at least one year in duration. In total, 699 health care providers and frontliners were enrolled (from December to February 2019). Data included all participant scores at day one at baseline, at year one, and at year 2 for their planned follow up visit. We performed a beta regression analysis using the R packages 'betareg' and 'emmeans'. Different models were developed with TOU as dependent variable and year, age, sex and profession as explanatory variables. TOU scores were above 9 at baseline as it was a prerequisite for participation, but dropped in the first year after participation (median TOU = 8, df=2, p-value=<0.0001). The decrease in TOU score over time differed between HCPs occupations (df=12, p-value <0.0001). A significant decrease difference in gender was only observed in the second year for year for women compared to men (median TOU = 8 vs 9, df=6, p-value =0.005) and in for age for the oldest compared to versus youngest categories (median TOU=8 vs 9, df=6, p-value =0.007). The study results suggest though the informed consent is a fact at the start of the study, it may be a concern in clinical studies lasting for at least one year. Once consent is given, it is a distant memory for most participants. One way to address this problem would be to reinstate participants at a well-defined point in the protocol.

5137

IMPROVED FACILITY BASED INTEGRATED SUPPORTIVE SUPERVISION- GAINS ON HEALTH SYSTEM STRENGTHENING IN OYO STATE

Esther Ayandipo[1], Motunrayo Fagbola[1], Tosin Orhorhamreru[1], Abimbola Olayemi[2], Olatayo Abikoye[2], Uchenna Nwokenna[2], Foluke Adeyemo[3], Olatunji Muideen[4], Gbolahan Abass[5], Arja Huestis[6], Allan Were[6], Thomas Hall[6], Veronica Momoh[7], Jules Mihigo[7]

[1]U.S. President's Malaria Initiative for States, Management Sciences for Health, Oyo, Nigeria, [2]U.S. President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [3]Oyo State Malaria Elimination Program, Oyo, Nigeria, [4]Oyo State Primary Healthcare Board, Oyo, Nigeria, [5]Oyo State Ministry of Health, Oyo, Nigeria, [6]U.S. President's Malaria Initiative for States, Management Sciences for Health, Arlington, VA, United States, [7]U.S. President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria

Nigeria is a high-burden country, which accounts for approximately one in four of the estimated 232 million cases worldwide (World Malaria Report 2022). The US President's Malaria Initiative for States supports Integrated Supportive Supervisory (ISS) visits to health facilities to support health system strengthening in Oyo state. The objectives of the ISS were to measure the quality-of-service delivery at the facilities, assess the functionality of various systems, update and improve the capacity of health workers. Quarterly visits to health facilities were made using an electronic checklist that covers: infrastructure, basic equipment, human resources, essential drugs, and service delivery for the malaria program. A total of 1625 health facilities were visited between September 2020 and December 2022

and 69% were revisited. Stock availability of artemisinin-based combination therapy (ACT)1, ACT4, Sulphadoxine-Pyrimethamine (SP) and rapid diagnostic test (RDT) showed an incremental improvement from 28%, 34%, 59%, 50% in September 2020 to 62%, 68%, 69% and 84% by December of 2021 and 87%, 94 %, 87 % and 96% by December of 2022. Reduction from 25% at baseline to 17% in December 2021 and 8% in December 2022 was noted in the number of patients who were RDT negative and incorrectly treated with ACT. State performance scores for infrastructure, basic equipment, human resource (job presence), essential medicines were noted to improve from 79%, 71%, 60% and 31% in September 2020 to 83%, 78%, 77% and 54% in December 2021 and 81%, 85%, 72% and 64% in December of 2022. Slight decline was noted in performance scores for infrastructure and human resource in 2022. A Pearson correlation coefficient test between number of visits and performance shows a strong positive correlation for infrastructure($r=.94$) ($p<0.01$), basic equipment($r=.91$) ($p<0.01$), essential medicine($r=.81$) ($p<0.01$) and human resource ($r=.93$) ($p<0.01$), thus revealing that the more visits to the facilities the better the improvement in performance. Following up with issues identified to ensure resolutions made during these visits is key to strengthening health systems.

5138

IMPROVED DATA QUALITY FROM AUTOMATED DHIS2 DATA EXCHANGE BETWEEN THE MALARIA RAPID REPORTING SYSTEM AND HEALTH MANAGEMENT INFORMATION SYSTEMS IN ZAMBIA

Japhet Chiwaula[1], Dingani Chinula[2], Ronelle Knit[3], Gift Sitenge[2], Ignatious Banda[1], Mercy Mwanza[1], Isaac Mwase[4], Celia Tusiime[2], Busiku Hamainza[1]

[1]National Malaria Elimination Centre, Lusaka, Zambia, [2]USAID Evidence for Health, Lusaka, Zambia, [3]Health Information Systems Programmes, Pretoria, South Africa, [4]U.S President's Malaria Initiative (PMI)/USAID-Health Office, lusaka, Zambia

The Zambia National Malaria Elimination Programme relies heavily on robust surveillance systems not only for malaria programming but also to track progress towards elimination and identification of transmission hotspots for targeted responses. However, the Ministry of Health (MOH) collects malaria data through three separate data systems, which makes it difficult to bring these platforms into one main data source for all malaria related indicators. The three platforms are Malaria Rapid Report System (MRRS) managed by National Malaria Elimination Centre (NMEC); Integrated Disease Surveillance and Response (IDSR) managed by the Zambia National Public Health Institute (ZNPHI); and Health Management Information System (HMIS) managed by the MOH.To identify data gaps and harmonize indicators across the three systems, USAID Evidence for Health (E4H) project in collaboration with NMEC conducted a comparative analysis to assess the performance of malaria surveillance systems in Zambia. Data collection was conducted through a review of existing data collection and reporting systems, datasets, data elements, indicators, and organizational units. This was followed by interviews with key stakeholders.The main issues identified across the three systems were: 1) Inconsistencies in the naming conventions of facilities, even where the same unique identifiers were used; 2) Data element and indicator naming conventions were not consistent across all three systems, and; 3) While all the three systems largely adhered to reporting timeliness, about 95% of the data elements and indicators were either named differently or collected with different disaggregation, thus affecting data quality as well as increasing the workload on data collectors. Based on these findings, MOH collaborating with E4H and partners has prioritized the harmonization of all malaria reporting systems through standardization of indicators, data elements and automation of data exchange across platforms to ensure that the overall reporting system functions as one reliable and effective source of information that improves data quality and reduces workload at data sources.

EXPLORING HEALTHCARE WORKERS' PERCEPTION AND CHALLENGES TO PRACTICING EFFECTIVE INFECTION PREVENTION AND CONTROL IN TERTIARY CARE HOSPITALS: A MULTI-CENTERED STUDY IN BANGLADESH

Md Golam Dostogir Harun[1], Lisa P Oakley[2], Shariful Amin Sumon[1], Aninda Rahman[3], Syed Abul Hassan Md Abdullah[4], Md Saiful Islam[5], Ashley R Styczynski[2], S. Cornelia Kaydos-Daniels[6]

[1]icddr,b, Dhaka, Bangladesh, [2]Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, [3]Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh, [4]Safetynet, Dhaka, Bangladesh, [5]University of New South Wales, Sydney, Australia, [6]Centers for Disease Control and Prevention (CDC), Dhaka, Bangladesh

Hospital-acquired infections (HAI) are a major public health burden globally. Deficits in infection prevention and control (IPC) knowledge and perceived barriers among healthcare workers (HCWs) put hospital staff, patients, and visitors at greater risk of acquiring infections. This study identified the perceptions and key challenges on IPC including barriers to compliance with IPC measures among HCWs in Bangladesh. Between August 2020 and March 2021, a qualitative exploratory study was conducted at eight tertiary care hospitals across Bangladesh. We conducted 32 in-depth interviews (IDIs) with hospital administrators, senior physicians, nursing matrons, and heads of cleaning staff from each hospital. We also facilitated 24 focus group discussions (FGD) with physicians, nurses, and cleaning staff. IDIs and FGD findings were compared and themes were triangulated across data collection strategies. Responses were analyzed using a thematic framework. The key barriers to effective IPC practices were a lack of dedicated personnel, irregular monitoring and audit, lack of equitable distribution of personal protective equipment, and insufficient supplies of soap and alcohol-based hand rubs. HCWs identified hospitals' physical layout and infrastructure were unsupportive of following IPC best practices. The barriers included the inaccessibility of hand hygiene stations; inadequate space to isolate patients; deficient HCW-to-patient ratios; and a lack of screening for patients with infectious diseases at admission. However, the implementation of basic IPC activities, such as environmental cleaning, was mostly hindered by the overcrowding of patients and visitors. The findings highlighted the critical IPC-related challenges faced by HCWs during their day-to-day service. The IPC practices were mostly hampered due to the insufficient supplies of IPC materials, unsupportive infrastructure, overcrowding of patients and visitors. The findings from this study could aid hospital leadership and policymakers in developing and implementing a tailored intervention to improve the IPC practices among HCWs to reduce the burden of HAIs.

5140

A PHASE I STUDY TO ASSESS THE SAFETY AND IMMUNOGENICITY OF A RECOMBINANT ADENOVIRUS-BASED VACCINE AGAINST PLAGUE

Arabella S V Stuart, Natalie G. Marchevsky, Xinxue Liu, Sagida Bibi, Federica Cappuccini, Christina Dold, Andrew J. Pollard, Christine S. Rollier

University of Oxford, Oxford, United Kingdom

Plague, an ancient and lethal zoonosis caused by the bacterium Yersinia pestis, continues to present a threat globally; both to populations in endemic regions, and due to it's potential as a bioweapon. Despite this, there is no current licenced and available vaccine in the Western sphere. The University of Oxford has developed a novel plague vaccine using the replication-deficient simian adenovirus-vector platform (ChAdOx1) and expressing known immunogenic Y.pestis LcrV and F1 antigens (ChAdOx1 Plague). The PlaVac Phase I trial (ISRCTN: 41077863) recruited healthy adult volunteers (18-55years) who received one or two doses of 5 x 1010 VP at intervals of 0 (Group 1), 0 & 56 (Group 2), or 0 & 182 (Group 3) days and were followed-up to day 365. The primary endpoint was safety and tolerability to day 28 post each dose. Secondary endpoints include antibody responses by ELISA at day 28 post each vaccination, and serious

adverse events (SAEs) and haematology and biochemistry parameters (safety bloods) throughout the trial. Forty-five participants were enrolled (33.3% female, 93.3% white ethnicity); 40 completed follow-up to D365. All participants in Groups 1 & 2 completed the vaccination schedule, n=2 in Group 3 did not receive a second dose for reasons unrelated to safety. The majority of solicited local and systemic adverse reactions were mild (Grade 1) in severity, and peaked within 3 days of dosing. Most common were: injection-site pain and tenderness, fatigue, headache, subjective feverishness, malaise and myalgia. The proportion of participants experiencing severe (Grade 3) adverse reactions was reduced after second dose. There were no serious adverse events or vaccine-attributable derangements of safety bloods during follow-up. Analysis of immunology endpoints is underway. These results demonstrate that the ChAdOx1 Plague vaccine is safe in adult humans, with tolerable reactogenicity. Completion of immunogenicity work will support progression to phase II testing.

5141

SCOPING REVIEW OF ACUTE FEBRILE ILLNESS IN WEST AFRICAN REGION, 2010-2020

Dallas M. Rohraff[1], Lilit Kazazian[1], Madeline R. Farron[1], Rewa K. Choudhary[1], Casey J. Siesel[1], Katie R. Hooker[1], Aishat Usman[2], Muhammad S. Balogun[2], Carol Y. Rao[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]African Field Epidemiology Network, Abuja, Nigeria

Acute febrile illness (AFI) is a frequent syndrome among persons seeking medical care in West Africa. Determining AFI etiology remains challenging in this region, where laboratory diagnostic capacity is limited. We conducted a scoping literature review to understand the coverage of AFI investigations in West Africa and to identify knowledge gaps regarding AFI etiology in the region. We conducted title and abstract searches of Medline, Embase, Global Health, and OVID databases using the search terms, in both English and French: "undifferentiated fever," "febrile," "non-specific fever," "suspected malaria," "presumed malaria," "presumptive malaria"; and either "West Africa" or the name of any country in ECOWAS (Economic Community of West African States). Using a standardized data collection form, we extracted data from studies that met the following inclusion criteria: published between January 1, 2010, and December 31, 2020; human studies; and AFI etiology determined by laboratory diagnostics. After deduplication, we screened 743 titles and abstracts. We performed full-text screening on 145 publications, and 76 studies were included for data abstraction. Nine of the fifteen (60%) ECOWAS countries were represented in the final publications, of which 57% of studies were in Nigeria. No consistent definition of AFI was utilized. Participant enrollment was most common in health facilities and included urban and rural populations. Studies reported a range in the number of pathogens tested (1-39), with 75% of studies testing for <3 pathogens. The most common laboratory diagnostic methods were microscopy (43%) and polymerase chain reaction (41%); 53% of studies utilized more than one laboratory diagnostic method. Malaria and dengue were the top two pathogens tested for and detected. Knowledge gaps remain about AFI etiologies in West Africa. Published data are helpful but insufficient to fully inform pathogen prioritization and guide the enhancement of surveillance systems in the region.

5142

ROOT CAUSE ANALYSIS OF HEALTH SECTOR VIOLENCE IN NEPAL: A QUALITATIVE EXPLORATION OF STAKEHOLDERS' VIEWS

Pradip Lamsal, Bharati Bhetwal sapkota, Rabin Pokharel, Gupta Bahadur Shrestha

Helping Hands Community Hospital, Kathmandu, Nepal

The task force conducted in-depth interviews with key informants, such as healthcare service providers, patient representatives, and other stakeholders, to map out the causes of violence against healthcare professionals and suggest coping mechanisms to create a violence-free environment. The interviews revealed that poor medical services delivery and increased patient awareness of their rights and access to justice are the main reasons for these acts of violence. The trust in medical services has been eroded by unqualified medical professionals, negative media influence, catastrophic out-of-pocket expenses, poor quality of care, commercialization of health services, poor monitoring of medical services, and a lack of professional ethics among some unscrupulous medical professionals. Despite socio-political development, violence against healthcare professionals is still on the rise due to increasing patient awareness and their willingness to seek justice. The healthcare system, healthcare professionals, government, and media all contribute to these disputes, but the poor quality of care, out-of-pocket payments, and negative media influence are the main factors driving the vicious cycle of complexity. To address these issues, the government, healthcare professionals, social actors, and healthcare facilities need to adopt strong policies and mechanisms to manage the problems that arise from these disputes. Trustworthiness and cost-effective treatment approaches by healthcare professionals and facilities are critical to preventing healthcare sector violence in resource-constrained settings. In conclusion, addressing the root causes of healthcare sector violence requires a multi-faceted approach that involves all stakeholders. Improving the quality of care, reducing out-of-pocket expenses, and promoting professional ethics among healthcare professionals are vital to rebuilding patient trust in the healthcare system and reducing violence against healthcare professionals.

5143

A POPULATION-BASED SEROLOGICAL SURVEY OF VIBRIO CHOLERAE ANTIBODY TITERS PRIOR TO THE 2022 CHOLERA OUTBREAK IN HAITI

Christy H. Clutter[1], Molly B. Klarman[2], Youseline Cajusma[2], Emilee T. Cato[2], Md Abu Sayeed[2], Lindsey Brinkley[2], Owen Jensen[1], Chantale Baril[3], V Madsen Beau De Rochars[2], Andrew S. Azman[4], Maureen T. Long[2], Derek Cummings[2], Daniel T. Leung[1], Eric J. Nelson[2]

[1]University of Utah, Salt Lake City, UT, United States, [2]University of Florida, Gainesville, FL, United States, [3]State University of Haiti, Port au Prince, Haiti, [4]Johns Hopkins University, Baltimore, MD, United States

After three years with no confirmed cholera cases in Haiti, an outbreak of Vibrio cholerae O1 emerged in October 2022. Levels of pre-existing antibodies provide an estimate of prior immunologic exposure, reveal potentially relevant immune responses, and set a baseline for future serosurveillance. We analyzed dried blood spots collected in 2021 from a population- weighted representative cross-sectional serosurvey in two communes in the Ouest Department of Haiti. We found lower levels of circulating IgG and IgA antibodies against V. cholerae lipopolysaccharide (LPS, IgG and IgA $p<0.0001$) in those below 5 years of age compared to those five years and older. Among a subset of patients with higher titers of antibodies, we were unable to detect any functional (vibriocidal) antibodies. In conclusion, the lack of detectable functional antibodies, and age-discordant levels of V. cholerae LPS IgG, suggest that populations in Haiti may be highly susceptible to cholera disease, especially among young children.

5144

ANTIBIOTIC USAGE IN LAYER FARMS: POTENTIAL ROLE IN EMERGENCE OF ANTIBIOTIC RESISTANCE

Khushbu Khushbu, Pallavi Moudgil, Vijay J. Jhadav, Deepak Soni

College Of Veterinary Sciences, Lala Lajpat Rai University Of Veterinary And Animal Sciences, Hisar, India

Tetracyclines are widely used for preventing diseases in poultry flocks since decades. It has been shown that low and sub-therapeutic doses of tetracyclines can enhance growth and production. However, their non-prudent use is leading to the occurrence of residues contaminated eggs and emergence of antibiotic resistant strains of bacteria. The present study aimed at detection of tetracycline residues in egg samples collected from

100 layer farms located in five different districts of Haryana, India. A total of 100 pooled egg samples were analyzed using High Performance Liquid Chromatography method for the simultaneous detection of residues of four tetracyclines viz., oxytetracycline, tetracycline, chlortetracycline and doxycycline. Out of 100 samples, 13 (13%) were found to be contaminated with residues of tetracyclines at concentration above limit of quantification. Out of these 13 samples, 1 (1%) was positive for tetracycline and 12 (12%) for chlortetracycline. None of the analyzed sample showed residues of oxytetracycline and doxycycline. Out of 13 samples, 5 (38.46%) (1 for tetracycline residues and 4 samples for chlortetracycline residues) exceeded the maximum residue limits established by Food Safety and Standards Authority of India. The presence of chlortetracycline and tetracycline residues above maximum residues limit in eggs is a matter of concern as it indicates non-prudent use of antibiotics in layer birds and possibility of unacceptable health risks to the consumers. The occurrence of these residues is also indicative of poor farm practices such as non-adherence to withdrawal periods. Thus, there is a need to generate awareness among layer farmers regarding the judicious antibiotics usage and sensitization for adherence to withdrawal protocols. Also, there is a need for formulation and implementation of strict legislations for the regulation of non-prudent antibiotic usage in poultry production.

5145

GLOBAL PUBLIC HEALTH INTELLIGENCE: WORLD HEALTH ORGANIZATION OPERATIONAL PRACTICES

Neil J. Saad[1], Blanche Greene-Cramer[1], Adedoyin Awofisayo-Okuyelu[1], Dubravka Selenic Minet[1], Maria Almiron[2], Krista Swanson[2], Masaya Kato[3], Phiangiai Boonsuk[3], Tamano Matsui[4], Manilay Phenxay[4], Aura Corpuz[5], Jeremias Naiene[5], Jukka Pukkila[6], Silviu Ciobanu[6], Etien Koua[7], George Sie Williams[7], Oliver Morgan[8], Ibrahima Socé Fall[1], Abdi Rahman Mahamud[1], **Esther L. Hamblion**[1], on behalf of the World Health Organization Public Health Intelligence Teams[9]

[1]World Health Organization, Geneva, Switzerland, [2]World Health Organization Regional Office for the Americas, Washington DC, WA, United States, [3]World Health Organization Regional Office for South-East Asia, New Dehli, India, [4]World Health Organization Regional Office for the Western Pacific, Manila, Philippines, [5]World Health Organization Regional Office for the Eastern Mediterranean, Cairo, Egypt, [6]World Health Organization Regional Office for Europe, Copenhagen, Denmark, [7]World Health Organization Regional Office for Africa, Brazzaville, Congo, Republic of the, [8]World Health Organization, Berlin, Germany, [9]Opeayo Ogundiran, Jean-Pierre Kimenyi, Enrique Perez, Mahmoud Hassan, Ka Yeung Cheng, Lauren MacDonald, Tshewang Dorji, Hannah Brindle, Viema Biakula, Ariuntuya Ochirpurev, Alessandro Miglietta, Anastasia Smirnova, Etsub Tahelew, Harsh Lata, Kaja Kaasik, Lidia Ezerska, Tatiana Metcalf, Savina Stoitsova, Switzerland

Early warning is essential for responding to acute public health threats and preventing public health emergencies of international concern. It is one of the most important activities of the World Health Organization (WHO). Therefore, WHO has adopted a robust approach to public health intelligence (PHI). This is underpinned by the International Health Regulations (2005) and focusses on the global detection and verification of acute public health events of potential international public health concern. Here, we describe WHO operational practices and outputs to further transparency and understanding of our operations. Data on signals and acute public health events reported in 2022 were extracted from internal WHO platforms, including the Event Management System (EMS), which is used for tracking health threats globally. Data were assessed, by the WHO Region and over time, using descriptive statistics in R. Globally, 6855 signals of potential public health threats were detected in 2022. After assessment and verification, 457 were considered acute public health events. These occurred in all WHO Regions although the majority of events were reported from African Region (27%, 125) and the Region of the Americas (25%, 112). The main cause of these events were infectious diseases (383, 83%), of which the three most commonly reported were mpox, cholera and, jointly, measles and dengue. In 2022, in response to these and ongoing events, 65 rapid risk assessments were disseminated. These assess the national, regional and global risk and guide response efforts. In addition, 109 bulletins and 88 announcements were posted on the Event Information Site to inform national country governments of acute public health events. Finally, to provide accurate and timely information to the public, 74 Disease Outbreak News (DON) reports were published. In conclusion, PHI is a key feature of global health architecture. Insight from WHO's practices can inform implementation and operations of other actors as well as identify areas of collaboration. Overall, PHI is vital for combatting novel, (re)-emerging and recurring health risk globally.

5146

EPIDEMIOLOGICAL INVESTIGATION OF GROUPED CASES OF DEATH DUE TO POISONING WITH CLOSTRIDIUM BOTULINUM IN A VILLAGE IN CÔTE D'IVOIRE, AFRICA, DECEMBER 2022 - JANUARY 2023

Damus Paquin Kouassi, Bénié Joseph Vroh Bi, Déby Arsène Kouamé, Sory Ibrahim Soumahoro, M'Bégnan Coulibaly, Opri Irika, Fatoumata Bamba, François Brizalékou

National Institute of Public Hygiene, Abidjan, Côte D'Ivoire

Two episodes of death cases occurred in the village of Kpo-Kahankro, in a health area in the Bouaké South health district, in Côte d'Ivoire. The first episode occurred on the night of Friday December 2, 2022, during which 20 children, 6 of whom died, presented with febrile gastroenteritis syndrome, adynamia and convulsions. This situation occurred in the context of funerals, but also of a Vitamin A supplementation campaign in the village. The second episode would have started on January 19, 2023, causing 58 cases including 16 deaths, where a notion of manipulation of an ecological niche was found; a traditional fetish. Epidemiological investigations were carried out respectively for the two episodes, the objectives of which were to: - Describe the phenomenon - Identify the cause - Propose control measures The investigations were carried out by a multidisciplinary team made up of epidemiologists, environmentalists, biologists, clinicians, hygienists and socio-anthropologists. Investigations consisted of questioning parents of patients and villagers, reviewing the medical records of patients and taking biological samples from patients and suspected sources of contamination. A total of 78 cases have been identified, including 22 deaths, i.e. a lethality of 28.2%. Among the cases, 76 children from 0 to 10 years old. The subjects who died were children (20 children) and subjects aged 50 and over (04 subjects). The signs presented were vomiting (71.1%), fever (52.6%), adynamia (39.5%), diarrhea (31.6%), coma (13.2%). Both episodes occurred after manipulation of an ecological niche during rituals. On more than ten blocks in the village, 47.7% of cases live in the block where the ecological niche is located. Clostridium botulinum was found on microbiological examination of the liquid contained in the niche. The destruction of the ecological niche has allowed the phenomenon to stop.

5147

THE PREVALENCE AND RISK FACTORS OF POST-TRAUMATIC STRESS DISORDER (PTSD): SYMPTOMS AMONG NURSES DURING THE COVID-19 PANDEMIC. A SYSTEMATIC REVIEW AND META-ANALYSIS

Santiago Hernandez, Adriana Campos, Jeegan Parikh, Jason Beckstead, Marc Lajeunesse, Derek Wildman

University of South Florida, Tampa, FL, United States

Since the first reported outbreak in Wuhan, China, the Coronavirus disease 2019 (COVID-19) has raised serious concerns globally. The COVID-19 pandemic has caused a severe psychological impact on healthcare workers (HCWs), and especially nurses, who are the most numerous and exposed front-line group. This systematic review and meta-analysis aim to summarize extant literature on the effects of the COVID-19 pandemic on the psychological health of nurses, particularly concerning the prevalence and risk factors for post-traumatic stress disorder (PTSD). A systematic search was conducted on Pubmed, Embase, and PsycInfo from March 2020 to September 2021. Articles were included/excluded

on predetermined eligibility criteria. A random-effects meta-analysis model was performed using proportions to determine the pooled prevalence of PTSD in nurses and evaluate sources of heterogeneity. Relatively high prevalence rates of PTSD were reported in the nurse population during the COVID-19 pandemic in eighteen different countries, globally. Risk factors associated with PTSD include having prior mental health co-morbidities, being a female, having insufficient protective conditions, working in an Intensive Care Unit, and having a young age. The overall pooled prevalence was 32.2% (95% C.I. = 0.239, 0.417) using a random-effects model in synthesizing 30 studies. The regression test of funnel plot asymmetry indicated a significant level of publication bias among studies. The COVID-19 pandemic is associated with significant levels of PTSD among frontline nurses globally. A high level of heterogeneity was observed across studies. Psychological, social, and administrative interventions should be implemented to mitigate heavy psychological distress in nurses.

5148

PERCEPTIONS OF YELLOW FEVER EMERGENCY MASS VACCINATIONS IN UGANDA: A QUALITATIVE STUDY

Lena Huebl[1], Aloysious Nnyombi[2], Aban Kihumuro[3], Denis Lukwago[4], Eddy Walakira[2], Ruth Kutalek[5]

[1]Department of Tropical Medicine, Bernhard Nocht Institute for Tropical Medicine & I Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Department of Social Work and Social Administration, Makerere University, Kampala, Uganda, [3]Department of Nursing and Health Sciences, Bishop Stuart University, Mbarara, Uganda, [4]Cluster Monitoring and Evaluation Lead, Rakai Health Sciences Program, Masaka, Uganda, [5]Unit Medical Anthropology and Global Health, Department of Social and Preventive Medicine, Center for Public Health, Medical University of Vienna, Vienna, Austria

Yellow fever (YF), a mosquito-borne viral hemorrhagic fever, is endemic in South America and Africa. Numerous outbreaks have been reported in Uganda. During emergency mass vaccinations 1.6 million people were immunized against YF in 2011 and 2016. The aim of this study was to explore local perceptions of YF emergency mass immunization to strengthen future vaccination campaigns. In this qualitative study we conducted 43 semi-structured interviews, 10 expert interviews and 4 focus group discussions. All 76 participants were from six affected districts with emergency mass vaccinations. We interviewed pregnant women and elderly people ≥ 65 years, who are excluded from YF vaccination except during mass immunization. For information on YF mass immunization participants relied on community sources. Information was spread door-to-door, during religious gatherings, in communal places, and via radio. Despite awareness campaigns most respondents had no knowledge of the vaccine, and it was unclear to them whether a booster dose was required. A concurrent presidential election during mass immunization led to distrust and rejection of the vaccine by the opposition. Moreover, distrust in YF vaccines was augmented by a lack of reliable and trustful information combined with a politicization of vaccination campaigns. Vaccination campaigns can never be seen completely detached from political systems and power relations. Thus, we recommend improving access to reliable information in remote areas affected by YF outbreaks. We advise to strengthen health education, communication, and engagement via respected and trusted community members.

ASSESSMENT OF THE AVAILABLE RESOURCES AND MEASURES TO CONTROL COVID-19 AT THE DISTRICT-LEVEL IN LIBERIA

Helena Juah Nyanti

Alliance for Conscious Change Leader, Paynesville, Liberia

COVID-19 continues to rapidly spread throughout the world, wreaking havoc on health professionals, health systems, collective mental health, and economies. In low-income countries, COVID-19 challenges frontline workers who may not have access to essential materials and skills for responding to the crisis. This study assessed available resources and measures used by District Surveillance Officers (DSOs) as part of the COVID-19 response in Liberia. A cross-sectional study was conducted between June-November 2021 using a census sampling approach, inviting all 93 DSOs via WhatsApp and email to complete and submit a survey via Google form. Descriptive statistical analysis was conducted. Microsoft Office Excel, frequency tables, and statistical software R studio version 4.2.0 were used appropiately. 75 responses were obtained from a possible 93 participants. DSOs responded that they were trained an average 2.71+1.23 (SD) times in their districts; whereas at the national level, they were trained on average 0.81+0.56 times. DSOs generally reported that measures taken at the district-level were representative of national recommendations, rather than locally developed measures. Respondents took an average 21.95±1.08 hours to investigate a suspected case. The majority of participants had case investigation forms (n=70, 93%) and PPE (n=68, 91%) as physical resources provided by the national level, whereas 8 (11%) of the participants indicated that their districts lacked financial means to conduct effective response efforts. Respondents reported use of similar response measures across districts, which indicates that DSOs were trained consistently about the COVID-19 response. DSOs had enough case investigation forms and PPE, but some took long to investigate cases. Others lacked internet access and electricity to produce reports effectively and efficiently such that there could be delayed reporting or underreporting of actual effort. Therefore, capacity building should support development of both content and physical resource needs for DSOs to ensure more timely reporting and case investigation.

ANTIBODY RESPONSE TO DIFFERENT COVID-19 VACCINES AMONG THE MIGRANT WORKERS OF BANGLADESH

Md. Imam Hossain[1], Protim Sarker[1], Rubhana Raqib[1], Md Ziaur Rahman[1], Rezaul Hasan[1], Chloe K. Svezia[2], Mahbubur Rahman[1], Nuhu Amin[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Dhaka, Bangladesh, [2]Rollins School of Public Health, Emory University, Atlanta, GA, United States

Due to the ongoing COVID-19 pandemic, various host countries such as Singapore imposed entry requirements for migrant workers including pre-departure COVID-19 seroconversion proof. To combat COVID-19 worldwide, several vaccines have acquired conditional approval. This study sought to assess antibody levels after immunization with different COVID-19 vaccines among the migrant workers of Bangladesh. Venous blood samples were collected from migrant workers who were vaccinated with different COVID-19 vaccines (n=675). Antibodies to SARS-CoV-2 spike protein (S) and nucleocapsid protein (N) were determined using Roche Elecsys® Anti-SARS-CoV-2 S and N immunoassay, respectively. All participants receiving COVID-19 vaccines showed antibodies to S-protein, while 91.36% were positive for N-specific antibodies. The highest anti-S antibody titers were found among the workers who completed booster doses (13327 U/mL), received mRNA vaccines Moderna/Spikevax (9459 U/mL) or Pfizer-BioNTech/Comirnaty (9181 U/mL), and reported SARS-CoV-2 infection in the last six months (8849 U/mL). The median anti-S antibody titers in the first month since the last vaccination was 8184 U/mL, which declined to 5094 U/mL at the end of six months. A strong correlation of anti-S antibodies was found with past SARS-CoV-2 infection ($p < 0.001$) and the type of vaccines received ($p < 0.001$) in the workers. Bangladeshi migrant workers receiving booster doses of vaccine, vaccinated with mRNA vaccines, and having past SARS-CoV-2 infection, mounted higher antibody responses. However, antibody levels waned with time. These findings suggest a need for further booster doses, preferably with mRNA vaccines for migrant workers before reaching host countries.

IMPACT OF ARTHROPODS ON THE TRANSMISSION OF DISEASES AND EPIDEMICS IN POPULATIONS WITH POOR HYGIENIC CONDITIONS AND INAPPROPRIATE BEHAVIORAL HABITS IN THEIR HOMES: CASE STUDIES ON POPULATIONS IN THE HEALTH DISTRICTS OF KINYINYA AND GISURU, NOVEMBER 2022 TO FEBRUARY 2023

Nkurunziza Africa Jerome

National Institute of Public Health, Bujumbura, Burundi

Burundi is an East Africa Country with 27,834 km square and a population of 12,574,569 (2022). The country is endemic for malaria, onchocerciasis, schistosomiasis and STH. Some districts have low trachoma rates, but none reach the MDA threshold for azithromycin. Cholera is sporadic every year. The districts of Kinyinya and Gisuru are 2 out of 4 districts in the health province of RUYIGI, they are located in the eastern part of the country and share the common border with Tanzania. The total population of the two districts in 2021 is 176,487. In 2021 Kinyinya district had 18 health centers and 2 district hospitals while GISURU had 14 health centers and 1 hospital. The two districts recorded 2,101 patients placed under observation for malaria with intestinal disorders or severe malaria, severe acute malnutrition. They received new hygienic facilities fitted out (2,473 standpipes, 3,400 hand washing devices, 4,765 garbage pits, 3,004 latrines. Despite all these efforts, the two districts periodically record unusual public health events manifested by skin manifestations with pruritus, followed by lesions and allergies.The investigation of the unusual public health event in these health districts led to the conclusion that the health situation is the consequence of poor hygiene conditions among the affected populations living with the hens. The inappropriate management of these scratch lesions can also be the gateway for pathogenic germs and cause infections of all kinds. The precarious hygiene in the population of these districts increases the risk of persistence of malaria and neglected tropical diseases in this endemic area. In addition, these insects could also be carriers of other transmissible diseases if they are not eliminated effectively. The cohabitation between humans and animals increases the risk of the emergence of zoonosis such as arboviruses which could cause new serious epidemics. Collaboration between the Administration, the Ministry of Public Health and the Ministry of Agriculture, Livestock and the Environment is essential in order to promote the hygiene of the population and healthy breeding without danger to human health.

5152

RAPID, LOW-COST, AND PORTABLE LAB-IN-A-BOX 'WHITE LOTUS' FOR POINT OF CARE TESTING OF SARS-COV-2 IN LOW MIDDLE INCOME COUNTRIES

Hitendra Kumar, Yoonjung Lee, Noah Toppings, Keekyoung Kim, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

Rapid identification of infectious diseases is critical in controlling their spread. Reverse Transcription Polymerase Chain Reaction (RT-PCR) is the primary approach for detecting large-scale infectious diseases but it is a complex and expensive process that involves several sample preparation and incubation steps at varying temperatures, making it impractical for low- and middle-income countries (LMIC). Reverse Transcription Loop-Mediated Isothermal Amplification (RT-LAMP) offers a simpler alternative to RT-PCR that maintains high sensitivity and the ability to detect variants, however, large-scale implementation of such tests is challenging as it requires sophisticated and expensive equipment, complex sample preparation and specialized storage conditions for assay reagents. Point-of-care tests (POCT) can overcome this challenge by providing low-cost means to perform a rapid diagnosis at the bedside without intricate steps. This study focused on developing a customized portable lab-in-a-box platform for rapid, sensitive, and patient-centered diagnostic approach based on LAMP. The POCT dubbed "White Lotus" was validated for COVID-19 diagnosis by using saliva samples and involved a quicker detection time with a heat inactivation step instead of RNA extraction. The White Lotus combined four essential components to perform the sequence of RT-LAMP steps: a heating block for thermal lysis followed by an isothermal incubator for amplification, a transilluminator module for visual detection, and a controller to provide user interface, control device components and wireless monitoring through a smartphone app. The White Lotus demonstrated excellent positive and negative agreement percentages (PPA 90.91% (30/33); NPA 96.55% (28/29)) compared to the reference RT-PCR, and significantly reduced instrument capital costs. This low-cost POCT will next be coupled with multiplexed diagnosis panels to differentiate between pathogens, species, and variants and could play a critical role in controlling the spread of infectious diseases, particularly in LMIC and resource-limited regions.

ASSESSMENT OF POINTS OF ENTRY, ISOLATION SITES AND COUNTIES PREPAREDNESS AND RESPONSE TO EBOLA VIRAL DISEASE, OCTOBER 2022, KENYA

Oscar Adidi Gaunya[1], James Marcomic Maraga[1], Stephen Antony Okumu[2], Maurice Owiny[3], Fredrick Odhiambo[3], Ahmed Abade[4], Josephine Githaiga[5], Emmanuel Okunga[6], Samuel Kadivane[6], Mitchel Sagala[7]

[1]Field Epidemiology & Laboratory Training Program Resident-Ministry of Health -Kenya, Nairobi, Kenya, [2]Field Eidemiology & Laboratory Training Program Resident-Ministry of Health -Kenya, Nairobi, Kenya, [3]Field Epidemiology & Laboratory Training Program Lecturer-Ministry of Health -Kenya, Nairobi, Kenya, [4]Field Epidemiology & Laboratory Training Program Resident advisor-Ministry of Health -Kenya, Nairobi, Kenya, [5]Field Epidemiology & Laboratory Training Program Director-Ministry of Health -Kenya, Nairobi, Kenya, [6]Division of Disease surveillance & Response-Ministry of Health -Kenya, Nairobi, Kenya, [7]Points Of Entry -Ministry of Health -Kenya, Nairobi, Kenya

Ebola Virus Disease (EVD) is a rare and deadly disease most commonly affecting people & non-human primates (monkeys, gorillas, & chimpanzees). The Health Department in Uganda confirmed the outbreak of Ebola Virus Disease (EVD) on September 20th,2022 with 130 cases & 43 deaths as of October 31, 2022. There were possibilities of the outbreak spreading to the neighboring 20 high-risk counties in Kenya whose level of preparedness & response was unknown. Therefore, we conducted an assessment to determine the level of preparedness & response in the counties in Kenya. The methodology used was the administration of a standardized questionnaire to determine the level of preparedness & response at the points of entry, ground crossings, & the County Health Management Team between October,20th 2022 to November, 2nd 2022. The surveillance pillars under assessment were; Coordination, Rapid Response Team, Case Management, Laboratory investigation, Infection Prevention & Control, Isolation & Referral system, Training, Risk Communication, Surveillance, & Community Engagement. The eligibility of the counties for assessment was based on the risk of exposure & proximity to the Uganda border which was experiencing an active Ebola virus disease outbreak. Data were analyzed using excel version 2016 to show the level of preparedness & response in percentages for each surveillance pillar. The results after the assessment were as follows; the average score for all nine surveillance pillars was 21%. The performance on individual pillars was as follows; Risk Communication 58%, Infection Prevention & Control 36%, Rapid Response Team 23%, Coordination 22%, Case Management 14%, Referral services 14%, Training 11%, Isolation & Surveillance 6.6% & Laboratory capacity 4% respectively. In conclusion, there was generally very poor performance on Ebola Virus disease preparedness & Response in all the counties under assessment. Therefore, we recommended all the high-risk counties to develop contingency/emergency plans specifically for Ebola Virus Disease and Disease outbreaks in the future.

SEROPREVALENCE AND RISK FACTORS ASSOCIATED WITH BRUCELLOSIS AMONGST LIVESTOCK AT KITENGULE RANCH IN KAGERA, TANZANIA

Beatus Lyimo[1], Charles Mayenga[2], Zachariah E. Makondo[2], Samson Lyimo[1], Lidia Munuo[1], Waziri Mlewa[3], Coletha Mathew[3], Maurice Byukusenge[4], Isabella M. Cattadori[4], Jessica A. Radzio-Basu[5], Rudovick R. Kazwala[3], Peter J. Hudson[4], Vivek Kapur[4], Joram Buza[1], Robab Katani[4]

[1]Nelson Mandela African Institution of Science and Technology, Arusha, Tanzania, United Republic of, [2]Tanzania Veterinary Laboratory Agency, Dar es Salaam, Tanzania, United Republic of, [3]Sokoine University of Agriculture, Morogoro, Tanzania, United Republic of, [4]Pennsylvania State University, University Park, PA, United States, [5]Penn State University, University Park, PA, United States

Brucella spp. are highly infectious pathogens causing brucellosis, a significant zoonotic disease affecting livestock, wildlife, and humans. In livestock, brucellosis could cause abortion and reduced milk production. Brucellosis is endemic in Tanzania; however, the prevalence of brucellosis amongst livestock species still needs to be fully established. This study aimed to determine the seroprevalence of brucellosis in cattle, goats, and sheep at Kitengule ranch in Kagera region of Tanzania. A cross-sectional sampling was conducted in early 2023. Blood samples were collected from cattle, goats, and sheep for serological evaluations. Epicollect was used to collect metadata to evaluate the risk factors associated with brucellosis. The presence of serum immunoglobulin against Brucella was tested using Rose Bengal Test and confirmed by cELISA. Descriptive statistics were used to determine the disease's prevalence among livestock species. Serum from 541 cattle and 185 small ruminants (goats/sheep) were tested for Brucella spp. The overall seroprevalence in livestock was 34.2%, comprising 68.1% in small ruminants (n=126, 95% CI= [60.9-74.8]) and 22.6% in cattle (n=122, 95% CI= [19.1-26.3]). Seroprevalence was significantly different between herds (Chi-square p< 0.0001). Multiple logistic regression analysis was run on variables, including animal species, herds, sex, and age. Results indicated that small ruminants are more likely to test positive than cattle (OR=14.0, CI= [6.7-31.4], p< 0.0001). Seropositivity was considerably higher in females than males (OR=3.1, CI= [1.2-4.2], p=0.001). Our results also showed that seropositivity was higher in older animals (> 2 years) compared with younger animals (OR=1.8, CI= [1.2-3.6], p=0.024). Our study suggests a high rate of seroprevalence of brucellosis (34.2%) at the Kitengule ranch compared to the national pooled average (8%). This calls for an urgent unmet need for further investigation of risk factors associated with brucellosis in livestock in other areas of Tanzania to help inform the development of evidence-based control plans benefiting both animal and public sectors.

5155

STRATEGIES AND POLICIES FOR SUSTAINABLE PATHOGEN GENOMIC SURVEILLANCE IN AFRICA: PRIORITIES, PROGRESS, AND CHALLENGES

Joseph N. Wangendo, Sofonias K. Tessema

Africa CDC, Addis Ababa, Ethiopia

Pathogen genomic surveillance is one of the crucial components of regional and global health security. Africa, with its diverse population and high burden of infectious diseases, has a critical need to integrate genomics into existing systems for outbreak detection and disease surveillance. Here we discuss the priorities, progress, and challenges of developing national strategies and policies for sustainable integration of genomic into existing disease surveillance, preparedness, and response in Africa. The strategies and policies are being developed through a collaborative effort involving Africa CDC, Member States, academia, non-governmental organizations (NGOs), and other stakeholders. The process involves mapping and review of existing policies, a situational analysis of the current state of genomic surveillance, and a stakeholder engagement process to identify priorities and gaps. The strategies and policies prioritize the strengthening of laboratory and bioinformatics infrastructure, the development of human capacity, and the establishment of sustainable funding mechanisms. The strategies also emphasize the importance of collaboration and sharing of data, resources, and expertise among member states and with other global partners. Furthermore, the policies highlight the need for ethical considerations in genomic surveillance, including data privacy, data governance and sharing. Implementation of the strategies and policies will require a multi-sectoral approach and sustained commitment from governments, donors, and other stakeholders. Overall, we highlight the need for sustained investment in genomic surveillance by African Union Member States and underscore the role of international collaborations and partnerships in achieving sustainable disease surveillance and response.

5156

A STUDY ON KNOWLEDGE, ATTITUDE AND PRACTICE (KAP) ON YELLOW FEVER AMONG COMMUNITY MEMBERS IN FOUR DISTRICTS AFTER AN OUTBREAK IN THE SAVANNAH REGION, GHANA

Millicent Captain-Esoah[1], Kwadwo K. Frempong[2], Chrysantus Kubio[3], Iddrisu Fuseini[4], Ishmael T. Alhassan[1], Enock Arthur[1], Matthew Gabienu[1], Abigail Mahama[1], Gloria Y. Deku[1], Daniel A. Boakye[2], Samuel K. Dadzie[2]

[1]Department of Applied Biology, School of Environment and Life Sciences, C. K. Tedam University of Technology and Applied Sciences, Navrongo, Ghana, [2]Department of Parasitology, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Accra, Ghana, [3]Ghana Health Service, Regional Health Directorate, Savannah Region, Damongo, Ghana, [4]Department of Statistics, C. K. Tedam University of Technology and Applied Sciences, Navrongo, Ghana

In 2021, Yellow Fever (YF) outbreak occurred in, rural and mostly nomadic communities in the Savannah Region of Ghana with over 40 deaths, including children. We determined the knowledge, attitude and practice (KAP) of community members in four districts in the Savannah Region using a questionnaire survey on 869 participants from June to July, 2022. Out of the total inhabitants interviewed, majority 702 (80.8%) indicated they heard about YF through healthcare personnel. 191(22.0%) had knowledge that transmission is through mosquito bites. Two districts; Central Gonja, 171 (86.5%) and Sawla-Tuna-Kalba 172 (86.0%) showed high knowledge on YF, the difference in participant's high-level knowledge on YF between the two districts is statistically not significant (Mann-Whitney test =25706.000 P = 0.262). while North Gonja 58 (21.6%) and West Gonja 52 (26.0%) showed little knowledge on YF. The difference in participant's low-level knowledge on YF between the two districts is statistically not significant (Mann-Whitney test=19900.000 P = 0.886). Among the participants 611 (70.3%) adopted the use of mosquito net, 605 (69.6%) clearing bushes and 636 (73.2%) cleaning of their surroundings as a mosquito preventive measure against the spread of YF. The vaccination of respondents or any household member was likely not influenced by time taken to access health service as explained by the lower correlation coefficient (Spearman Rho correlation coefficient=0.264). The emergency mass YF vaccination carried out by the Ghana Health Service in response to the outbreak in the region could have contributed to the high knowledge of community members on the disease. Regular education on YF in these YF hotspot communities in the Savannah Region and Northern Ghana as a whole will help increase awareness and consequently reduce the risk of transmission of the disease.

5157

COMMUNITY ENGAGEMENT IN A NEW TRIAL SITE OF THE PARTNERSHIP FOR RESEARCH ON EBOLA VACCINATION IN MALI

Samba Diarra

USTTB, Bamako, Mali

Since the 2014 Ebola virus disease outbreak in West Africa, several clinical trial initiatives have been implemented to accelerate the search for an effective vaccine against the disease. We report on a community engagement process to identify issues related to the understanding and

acceptability of participation in a community-based vaccine trials of the Partnership for Research on Ebola Vaccination (PREVAC) in Mali. To identify a community engagement strategy for a new vaccine against Ebola in Mali. A questionnaire and focus groups (8) involving heads of households, women and community leaders were conducted. 22 community mobilizers were trained on Ebola vaccination and on responsible conduct of research and ethics. “Ice-breakers” meetings with traditional authorities were conducted to establish a participatory framework between the research team and the communities. Study participants expressed a very good knowledge of Ebola, including mode of transmission (32%), prevention (88%) and 97,9% recognized the importance of vaccination. The baseline survey showed that 75,2% were inclined to participate in the vaccine trial. The community engagement strategy, through the series of “Icebreakers” meetings and the interface between the communities and the research team made it possible to dispel the concerns raised for non-participation in clinical trials (lack of confidence in a new vaccine). They made it possible to achieve a retention rate of 94% of the volunteers who made the scheduled 9 visits in the research protocol and more than 4000 home visits. The participatory approach through inclusion of traditional community legitimacy, awareness and information on the vaccine process helped to build trust and acceptability of the vaccine trial. This experience gathered during PREVAC with the NIH can be used to guide future vaccine trials in developing countries.

5158

COVID-19 ATTITUDES AND VACCINE HESITANCY AMONG AN AGRICULTURAL COMMUNITY IN SOUTHWEST GUATEMALA: A CROSS-SECTIONAL SURVEY

Neudy Rojop[1], Diva M Calvimontes[1], Edgar Barrios[1], Molly M. Lamb[2], Alejandra Paniagua-Avila[3], Jose C. Carlos[4], Lindsey M. Duca[4], Chelsea .. Iwamoto[4], Anna N. Chard[4], Melissa Gomez[1], Kareen Arias[1], Guillermo A. Bolanos[1], Emily .. Zielinski-Gutierrez[4], Eduardo .. Azziz-Baumgartner[4], Maria R. Lopez[5], Celia Cordon-Rosales[5], Edwin J. Asturias[6], Daniel Olson[6]

[1]Fundacion para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala, [2]Colorado School of Public Health, Aurora, CO, United States, [3]Mailman School of Public Health, Columbia University, New York, NY, United States, [4]Center for Disease Control and Prevention, Atlanta, GA, United States, [5]Universidad del Valle de Guatemala, Guatemala City, Guatemala, [6]University of Colorado School of Medicine, Aurora, CO, United States

Despite offering free-of-charge COVID-19 vaccines starting July 2021, Guatemala has one of the lowest vaccination rates in Latin America. During September 28, 2021 to April 11, 2022, we conducted a cross-sectional survey of community members adapting a Center for Disease Control and Prevention (CDC) questionnaire to evaluate COVID-19 vaccine access and hesitancy. Of 233 participants ≥12 years, 127 (55%) received >1 dose of COVID-19 and 4 (2%) reported prior COVID-19 illness. Persons ≥12 years old (eligible for vaccine at the time) who were unvaccinated (n=106) were more likely to be female (73% vs 41%, p<0.001) and homemakers (69% vs 24%, p<0.01) compared with vaccinated participants (n=127). Among those >18 years old, vaccinated individuals were more likely to be moderately or very worried about COVID-19 (n=36, 31%) compared to unvaccinated individuals (n=13, 18%; p=0.04); unvaccinated individuals were more likely to have little no confidence in public health institutions (55% vs 38%, p=0.02). Participants’ primary reported motivations for COVID-19 vaccination were to protect family/friends (68% vaccinated vs 73% unvaccinated, p=0.54), to protect their own health (24% vs 11%, p<0.01), and to protect the health of the community (2.5% vs 3%, p=0.94). Community- and/or home-based vaccination programs, including vaccination of families through the workplace, may better reach female homemakers and reduce inequities and hesitancy, and a such a program is ongoing. In follow-up, beginning March 14, 2023, we began a repeat survey in the same household cohort to assess changing attitudes and access around COVID-19 and COVID-19 vaccines as well as drivers (risk associations) of those changes.

5159

DESCRIPTION OF AN ACTIVE SURVEILLANCE SYSTEM CONDUCTED IN OUTPATIENT CLINICS FOR PRIORITY ACUTE IN FECTION SYNDROMES IN GUATEMALA

Kailin Chen[1], Juan Carlos Romero[2], Maria Renee Lopez[2], John P. McCracken[1], Laura M. Grajeda[1], Celia Cordon[2]

[1]University of Georgia, Athens, GA, United States, [2]Universidad del Valle de Guatemala, Guatemala City, Guatemala

Due to the high burden of infectious disease and limited diagnostic capabilities in Guatemala, the Vigilancia integrada colaborativa de enfermedades infecciosas agudas prioritarias (VICo-IP) was established to estimate the burden and characterize etiologies for key infectious disease syndromes. VICo-IP operates in Quetzaltenango, a department with a majority urban-dwelling population of nearly 800,000. We examined data from two ambulatory clinics in the San Juan Ostuncalco (SJO) and El Palmar municipalities, which differ in climate, altitude, and ethnic makeup. Patients of all ages who provide consent or assent are screened for signs of acute respiratory (ARI), diarrheal (ADI), or febrile (AFI) syndromes, and epidemiological data and samples (nasopharyngeal and/or oropharyngeal swabs, stool, blood, and urine) are systematically collected. Etiologies are identified by LIAT, FilmArray, and PCR testing. Analysis of surveillance data from a period of continuous enrollment (1 March 2022 to 25 January 2023) reveal differences in disease frequency, notably respiratory and diarrheal, between the two clinics. Overall, of the 644 enrolled participants, mean age was 27.6, and 57.8% were female. 92.2% of patients presented with symptoms of ARI, 16.3% ADI, and 28.9% AFI. 97.2% provided samples for etiological testing. Few cross-syndrome etiologies were seen. SARS-CoV2 (198/409, 48.4%) was the most common respiratory disease etiology found, whereas E. coli strains (12/37, 32.4%) and Leptospira bacteria (7/13, 53.8%) were the most common diarrheal and febrile etiologies identified, respectively. Significantly more laboratory-confirmed diarrheal disease was seen in El Palmar (OR: 14.1, 95% CI: 2.18-283) than SJO. SJO demonstrated significantly greater laboratory-confirmed burden of respiratory disease (OR: 1.80, 95% CI: 1.19-2.75) than El Palmar, indicating local site characteristics should be used to decide on control and mitigation interventions. Examining syndromic data from similar-level facilities can assist public health officials in better understanding population needs and tailoring appropriate interventions.

5160

STRENGTHENING HEALTH SYSTEMS FUNDAMENTALS CAN PROTECT COUNTRIES FROM COVID-19: A RE-EVALUATION OF THE GLOBAL HEALTH SECURITY INDEX AND ITS SUB-DIMENSIONS

Tyler Headley[1], Sooyoung Kim[2], **Yesim Tozan**[2]

[1]New York University Abu Dhabi Campus, Abu Dhabi, United Arab Emirates, [2]New York University School of Global Public Health, New York, NY, United States

The Global Health Security Index (GHSI) is a composite index developed in 2019 to assess countries’ preparedness for epidemics and pandemics under the International Health Regulations framework. However, recent research showed that the GHSI was not predictive of countries’ performance during the COVID-19 pandemic, raising questions about its validity as an assessment tool. We empirically explored if and how subcomponents of the GHSI were associated with their ability to safeguard essential health service delivery during the pandemic.Using a difference-in-difference methodology, we assessed the relationship between countries’ ratings pertaining to their overall preparedness and six subcategories and childhood immunization coverage rates during the pandemic. We operationalized the GHSI 2019 and its 6 subcomponents and 34 indicators to assign countries to the treatment (above 80th percentile) and control groups and defined 2020 and 2021 as post-pandemic years. The results were crossed-checked using the World Bank’s governance indicator to ensure the reliability. All analyses were adjusted for potential confounders. While the overall effect of the GHSI on childhood immunization coverage

rates during 2020-2021 was statistically non-significant, countries' commitments to sharing data (coef: 6.0; p =0.017), infrastructure (coef: 3.2; p <0.001), and overall environmental risks (coef: 2.94; p <0.001) were the subcategories most positively associated with preventing declines in childhood immunization coverage. These results were confirmed with the World Bank's governance indicators, which demonstrated that countries' rule of law (coef: 3.58; p <0.000), effective governance (coef: 3.27; p <0.000) and control of corruption (coef: 3.16; p <0.000), were most strongly associated with preventing the declines.Our findings underscore the importance of core health system capacities that shape countries' overall risk landscapes in mitigating the public health consequences of the COVID-19 pandemic and provide prioritization guidance to policymakers to improve countries' preparedness for future epidemics and pandemics.

5161

THE SYNERGISTIC IMPACT OF UNIVERSAL HEALTH COVERAGE AND GLOBAL HEALTH SECURITY ON HEALTH SERVICE DELIVERY DURING THE COVID-19 PANDEMIC: A DIFFERENCE-IN-DIFFERENCE-IN-DIFFERENCE STUDY OF CHILDHOOD IMMUNIZATION COVERAGE FROM 192 COUNTRIES

Sooyoung Kim[1], Tyler Headley[2], Yesim Tozan[1]

[1]New York University School of Global Public Health, New York, NY, United States, [2]New York University Abu Dhabi Campus, Abu Dhabi, United Arab Emirates

Universal health coverage (UHC) and global health security (GHS) are two high-priority global health agendas that seek to foster health system resilience against health emergencies. Many countries, however, have had to prioritize one agenda over the other due to scarce resources and political pressures. To aid policymakers' decision-making, this study investigated the individual and synergistic effects of countries' UHC and GHS capacity in safeguarding essential health service delivery during the COVID-19 pandemic. We used a quasi-experimental difference-in-difference and difference-in-difference-in-difference methodology to quantify the relationship between 192 countries' progress towards UHC and GHS and those countries' ability to provision 12 essential childhood immunization services between 2010 and 2021. We used the 2019 UHC Service Coverage index to divide countries into a "high UHC group" (above 80th percentile) and the rest, and similarly used the 2019 GHS Index to divide countries into a "high GHS group" and the rest. All analyses were adjusted for potential confounders.Countries with high UHC scores prevented a 3.34% (95% CI: 2.17%, 4.52%; p-value < 0.001) reduction in immunization coverage across 2020 and 2021. Countries with high GHS scores prevented a 2.02% (95% CI: 0.44%, 3.59%; p-value = 0.012) reduction in immunization coverage in 2021 but no statistically significant effect in 2020. The DiDiD model showed that high GHS capacity needed to be augmented with high UHC to prevent a decline in immunization coverage while high UHC alone was able to safeguard immunization coverage during the pandemic.This study found that greater progress towards both UHC and GHS safeguarded essential health service delivery during the pandemic but only progress towards UHC was both a necessary and likely sufficient element for yielding this protective effect. Our results call for strategic investments into both health agendas and future research into possible synergistic effects between the two health frameworks.

5162

WASTEWATER GENOMIC SURVEILLANCE AS AN APPROACH TO TRACK INFECTIOUS DISEASES PATHOGENS IN THE AGADIR REGION OF MOROCCO

Ahmed Belmouden[1], Maryem Wardi[1], Mohamed Aghrouch[1], Fatima Boubrik[1], Abdellah Lotfy[2], Zohra Lemkhente[1]

[1]Ibnou Zohr University, Agadir, Morocco, [2]Souss-Massa Ministry of Health delegation, Agadir, Morocco

Wastewater genomic surveillance is a promising approach to monitor pathogens that may constitute a health threat for humans and animals. This approach can be applied as an early warning tool and to enable acting before pathogens spread to the general population. In collaboration with Moroccan health and environmental authorities, we established a platform of experimental and analytical resources to monitor antibiotic resistance genes (ARGs) and SARS-CoV-2 dynamics. The workflow developed comprises sample collection and processing, nucleic acid purification, and downstream genomic pipelines using a real-time quantitative PCR and NGS platforms. Using these resources, first we demonstrate the feasibility of ARGs monitoring by successful profiling of the resistome in 6 wastewater treatment plants (WWTPs) in the Agadir region for the first time in Morocco, providing a better understanding of the status of ARGs and highlights their dissemination potential. Second, we performed genomic surveillance of SARS-CoV-2 during the initial Omicron wave in January 2022. Following automated RNA extraction, SARS-CoV-2 N gene was qPCR amplified and quantified. The results showed that viral load in wastewater influents from these WWTPs ranged from 52.7E+03 to over 75.8E+04 viral N gene copies/L. The evolution of the number of confirmed cases identified by the Ministry of Health, during the same period and in the same geographical area correlates with our viral load findings. NGS sequencing of SARS-CoV-2 genomes recovered from wastewater clearly indicated the predominance of the BA1 variant (99%) with less than 1% for the BA2 variant. Furthermore, the number of infected individuals was predicted by using a SEIR-model and the mass rate of SARS-CoV-2 RNA in wastewater. The results estimated the number of infected persons to be ~25 fold higher than the reported number of cases. This may be due to asymptomatic and undiagnosed cases, and individuals who are positive but do not undergo testing or report to clinics. These results highlight the power of wastewater genomic surveillance as a valuable tool to monitor, better understand and control pathogens.

THE VIRTUAL BIOREPOSITORY SYSTEM FOR OPEN ACCESS TO SAMPLES: THE ONLINE DELPHI PRIORITIZATION OUTCOME

Amy Price[1], Layla Abdulbaki[2], Judith Giri[3], **Julia Poje**[3], Geoffrey Winstanley[3], Zoe Steinberg[3], Thomas Jaenisch[3], May C. Chu[3]

[1]Stanford School of Medicine, Stanford, CA, United States, [2]Oakland University, Oakland, CA, United States, [3]Colorado School of Public Health, Aurora, CO, United States

An equitable, federated, virtual biorepository system (VBS) with stewardship focused at local sites broadens access to specimens and associated data for outbreak-prone infectious diseases. This would accelerate the development of diagnostics, assessment of vaccine efficacy, and support surveillance and research that is reflective of the populations being served. The VBS is aligned to complement other specimen-sharing efforts as a force multiplier to strengthen global tools for countering epidemics. Our work reveals significant gaps in diversity, equity, and inclusion in accessing specimens/data especially for LMICs. We used an online Delphi process (oDp) as an inclusive approach to engage stakeholders to re-imagine and empower low-resource partners to drive the VBS concept at scale, where they will prioritize the benefits and define sustainable operations in their context. Participants included principal investigators (23), public health/clinical laboratories (9), research institutions (22), commercial diagnostics (3), and biorespository managers (5) working from Africa (15), N. America (10), Europe (9), Latin America (9) and Asia-Pacific (5). We posed 34 questions for participants to rank preferences presented as % in agreement. There was complete consensus (100%) about the need for collecting clinically well characterized specimens and associated data and implementing a cost recovery scheme; followed by serially collected blood and blood-derived samples (95%), access to qualified reference standards (93%), and willingness to share specimens (92%). The VBS is envisaged to combine centralized and federated components (82.9%) with networking and collaboration as the highest ranked benefits. Regulations prohibiting sharing samples out of country (56%) were seen as the greatest challenges. By using the oDp, we were able to successfully use a grassroots effort to

inform us as to our next steps. We suggest that the oDp can be a useful tool to help identify priorities and streamline the work plan for other complex global good products.

THE VIROME OF PHLEBOTOMINE SAND FLIES FROM SELECT REGIONS OF KENYA

Jane W. Thiiru[1], Solomon K. Langat[2], Stephanie Cinkovich[3], Santos Yalwala[4], Samoel Khamadi[2], Jaree Johnson[5], Justus Onguso[1], Eric Garges[4], Elly Ojwang[4], Fredrick Eyase[4]

[1]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [2]Centre for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya, [3]Armed Forces Health Surveillance Division, Global Emerging Infections, Surveillance Branch, Silverspring, MD, United States, [4]Department of Emerging Infectious Diseases , United States Army Medical Research Directorate -Africa, Nairobi, Kenya, [5]Armed Forces Health Pest Management Board, Silverspring, MD, United States

Sand fly-associated viruses are inadequately researched in Sub-Saharan Africa. Whereas recent surveillance studies in parts of Kenya have revealed a number of arboviruses circulating among sand fly populations, our overall knowledge of the identity of viruses in these vectors remains limited. The present study used metagenomics, viral isolation and Next Generation Sequencing (NGS) to characterize RNA viruses in sand flies. Sand flies were collected between September 2020 and July 2022 in Baringo, West pokot, Nakuru, Kisumu, Kilifi, Kwale and Isiolo counties in Kenya using CDC light traps. The collections were sorted into pools of 10 or less flies and homogenized. Virus isolation was performed in vero cells with CPE positive samples being subjected to NGS. For metagenomic analyses, super-pools were generated based on site of origin. Libraries were prepared and sequenced on the Iseq 100 platform. The unassembled short reads were classified using Kraken 2 metagenomic sequence classifier and mapped to the genomes of isolated viruses. Contigs were generated in Megahit and further taxonomic classification done. Two CPE positive samples resulted in the isolation of the Koutango lineage of West Nile Virus (WNV) and Bogoria virus, a phlebovirus. Read classification led to identification of several viral sequences including Vesicular stomatitis virus, Maraba virus, Carajas virus, Piry virus, Koutango virus (WNV) and Bogoria viruses. From assembled metagenomic sequences, 14 phylogenetically distinct insect specific viruses belonging to Dicistroviridae, Chuviridae, Iflaviridae, Nodaviridae, Tombusviridae, Polycipiviridae families and Negevirus were identified. These results have shown that sandflies from Kenya harbour diverse RNA viruses, some of which are of public health importance.

SYSTEMATIC REVIEW ON TICKS AND TICK-BORNE DISEASES IN ASIA AND AUSTRALIA

Nora G. Cleary[1], Joanna Pacori[1], Michael E. von Fricken[1], David Pecor[2], Alex Potter[2], Yvonne-Marie Linton[2], Cynthia Tucker[2]

[1]George Mason University, Department of Global and Community Health, Fairfax, VA, United States, [2]One Health Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Globally, tick-borne pathogens of human concern pose a threat to deployed war fighters (DWFs). DWFs pyrethroid treated uniforms are their first line of defense against tick vectors. As climate change shifts vector habitats and affects the value of insecticides for protection, DWFs remain at risk. A systematic literature review was performed to strengthen the knowledge of tick species and their associated pathogens in areas where soldiers may be deployed or stationed.This review focused on the INDOPACOM region including Australia, Bhutan, Guam, Korea, Palau, and the Philippines. Search terms included a variety of ticks and tick-borne diseases in these countries following PRISMA guidelines from 1900 until 2022. The initial search yielded 8,433 articles and 1,184 articles met full review. Full review articles were extracted and uploaded to VectorMap comprising 338 articles from Australia (170), Bhutan (1), Guam (3), Korea (145), Palau (0), and the Philippines (19). Records from these countries included the following hard tick genera: Amblyomma, Aponomma, Dermacentor, Haemaphysalis, Hyalomma, Ixodes and Rhipicephalus, and two soft tick genera: Argas and Ornithodoros. The largest variety of tick species collected were from Australia followed by the Republic of Korea. Numerous pathogens were detected using PCR or IFA including species from the following genera: Anaplasma, Borrelia, Babesia, Coxiella, Ehrlichia, Francisella, Rickettsia, Theileria, and Flavivirus. Ticks were collected from various mammalian and avian hosts including humans.These records contained an abundance of pathogens in ticks from Asia and Australia with the potential to cause human disease. Maps showing the distribution and prevalence of tick species and corresponding pathogens can inform control measures. As vector habitats and behaviors adapt to climate change, continued surveillance will be vital to understanding the risk towards human health. Gaps for future surveillance were noted, especially in Bhutan, Guam, and Palau where few records were found. This valuable knowledge can ensure well informed decisions are made to protect DWFs in these areas.

5166

MITE-TRANSMITTED INFECTIOUS DISEASES: WIDELY DISTRIBUTED AND NEGLECTED

James Henry Diaz

LSU School of Public Health, New Orleans, LA, United States

Mites are among the smallest arthropod vectors of infectious diseases (IDs) with most species barely visible at less than one µ in length. Bites by house mouse mites can transmit Rickettsia akari, the causative bacterial pathogen of rickettsialpox. Bites by larval trombiculid mites can transmit Orientia tsutsugamuchi, the causative bacterial pathogen of scrub typhus. Rickettsialpox occurs worldwide, and scrub typhus is considered regionally confined to the Tsutsugamuchi Triangle in Asia and Northern Australia. The ecology, epidemiology, clinical manifestations, differential diagnosis, laboratory diagnosis, management, and prevention of mite-transmitted IDs are presented. Internet search engines are queried in order to provide evidence that mite-transmitted IDs are both widely distributed and neglected. Rickettsialpox is widely distributed for several reasons including its animal reservoir, the common house mouse, and its mouse mite vector are ubiquitous; and subclinical and doxycycline-cured cases are often underreported worldwide. Scrub typhus is also widely distributed for several reasons including a global distribution of potential larval mite vectors with new cases of scrub typhus described in the Middle East and South America, far away from the Tsutsugamuchi Triangle. Rickettsialpox and scrub typhus are super-neglected and not included among the WHO listing of neglected diseases. Neglect of these mite-transmitted IDs is evidenced by a lack of research and new drug development as compared to mosquito-borne and tickborne IDs. In addition, there are no vaccines to prevent rickettsialpox and scrub typhus. Targeted research into mite-transmitted IDs, new drug development to counter increasing doxycycline resistance and replace chloramphenicol, and vaccines, especially for scrub typhus, are needed now.

5167

POPULATIONS STRUCTURE ANALYSIS OF PHLEBOTOMUS PAPATASI POPULATIONS USING TRANSCRIPTOME MICROSATELLITES: POSSIBLE IMPLICATIONS ON GENE EXPRESSION

Omar Hamarsheh[1], Mary Ann McDowell[2]

[1]Al-Quds University, Abu Dies, Palestinian Territory, [2]University of Notre Dame, Notre Dame, IN, United States

Phlebotomus papatasi considered the primary vector of Leishmania major parasites which causes zoonotic cutaneous leishmaniasis (ZCL) in the Middle and far East and in North Africa. P. papatasi populations have been extensively studied and revealed the existence of different genetic populations and subpopulations over its large distribution range. Genetic diversity and population structure analysis using transcriptome microsatellite markers is important to uncover the vector distribution dynamics, an essential for controlling ZCL in endemic areas. In this study, we investigated for the first time the level of genetic variation using expressed sequence

tags EST-SSRs among field and colony P. papatasi samples collected from 25 different locations in 11 countries. The genetic variation reveals the existence of high-level population structures expressed in five distinct populations. These great genetic differences in expressed genes may enable P. papatasi to adapt in different environmental conditions along its distribution range and affects dispersal and control of this species probably by upregulating insecticide resistant genes which is common among vectors of infectious diseases. Moreover, anthropogenic changes can also lead to an increase in the dispersal of sand flies and hence the disease transmission. The investigation of population structuring of P. papatasi may have a great contribution to the L. major containment efforts in these countries. Moreover, the level of genetic variation among these populations may have a great benefit for understanding parasite-vector interaction and contribute to the efforts of vaccine development based on P. papatasi salivary proteins.

5168

RELATIONSHIP BETWEEN ENVIRONMENTAL FACTORS AND PHYSICO-CHEMICAL PARAMETERS IN THE DISTRIBUTION AND DENSITY OF MOLLUSC INTERMEDIATE HOSTS OF SCHISTOSOMIASIS IN SENEGAL

Cheikh Binetou Fall, Sylla Khadime, Soulèye Lelo, Isaac Manga, Roger Tine, Magatte Ndiaye, Doudou Sow, Babacar Faye
University Cheikh Anta Diop, Dakar, Senegal

A change in the epidemiology of bilharzia has been noted with the appearance of hybrid strains in northern Senegal. The objective of this work is to study the relationship between physico-chemical parameters (water temperature, conductivity, salinity, pH, total dissolved solids), environmental factors (plastic waste, vegetation) and the distribution of molluscs in 14 sites in the Ferlo valley, Lac de Giers and Taouey canal.At each site, prior to any survey, information concerning the habitat was collected, namely the geographical coordinates, pollution, type of vegetation and the presence of animals. To measure the physico-chemical parameters such as water temperature, conductivity, salinity, pH and total dissolved solids we used multiparametric tester with digital probes PC60 (APERA instruments). The technique consisted of immersing the probes in the water to collect these data.The surveys identified 8 species of molluscs, four of which are involved in the transmission of human schistosomes (Biomphalaria pfeifferi, B. globosus, B. truncatus, B. senegalensis) and four other species that are not involved in the transmission of schistosomiasis (B. forskalii, Lymnaea natalensis, Bellamya unicolor and Mellanoides tuberculata). The density of molluscs collected is a function of the nature of the site. This study also shows that environmental parameters (vegetation, pollution) and physicochemical parameters (total dissolved solids, salinity, pH) have effects on the distribution and density of mollusc populations intermediate host of human schistosomes.

5169

FIRST RECORD OF MOSQUITO BORNE SINDBIS VIRUS <GENOTYPE I> IN BURKINA FASO, WEST AFRICA

Patindé Didier Alexandre Kabore[1], Patricia Gil[2], Philippe Van de Perre[3], Thierry Baldet[2], Serafín Gutiérrez[2], Roch K. Dabiré[1]
[1]Institut de recherche en sciences de la santé, Bobo-Dioulasso, Burkina Faso, [2]Le Centre de coopération internationale en recherche agronomique pour le développement, Montpellier, France, [3]University of Montpellier, Montpellier, France

Several mosquito-borne viruses represent a major threat to human health worldwide. Beyond those well-known pathogens, a large diversity of arboviruses transmitted by mosquitoes remains largely unstudied despite an established potential for emergence in some cases. Beyond a high diversity, mosquito arboviruses have also shown an impressive capacity for spread into new regions. Thus, health services require updated characterisations of the arbovirus diversity in a given region to optimize diagnostics. Nevertheless, such updates are rarely carried out, especially in low-income countries. Thus, diagnostics of potential arboviral infections is often limited to high-profile viruses, like dengue virus. This situation probably leads to a large fraction of undiagnosed cases due to arboviruses neglected or recently established in a region. Here, we have characterized the diversity of mosquito-borne viruses in two regions of Burkina Faso. To this end, we have screened a recent and large mosquito collection using untargeted metagenomics. The analysis focused on two mosquito species, Aedes aegypti and Culex quinquefasciatus, considered among the most important vectors of arboviruses worldwide. The screening detected Sindbis virus (SINV, Togaviridae) for the first time in Burkina Faso. This zoonotic arbovirus has spread into Europe from Africa and is the cause of disease outbreaks mainly in Europe. SINV was detected at low prevalence and only in C. quinquefasciatus from one of the regions and at a single year. A phylogenetic analysis placed the nearly-full SINV genome within the cluster of Central African sequences at the origin of the strains that have spread into Europe. Thus, this result extends the region as potential SINV source to Western Africa. Finally, a virus isolate was obtained for future experimental studies. Overall, our results provide insights into the current arbovirus diversity in Burkina Faso and can help to improve diagnosis. Moreover, the approach used here could be applied to other regions in need of a better characterization of the arbovirus diversity in mosquitoes.

5170

CHANGING EPIDEMIOLOGICAL PATTERN OF VISCERAL LEISHMANIASIS IN NEPAL

Lila Bikram Thapa
Department of Health Services, Kathmandu, Nepal

On the Indian subcontinent, visceral leishmaniasis VL is targeted for elimination as a public health problem by 2017. Nepal has achieved the elimination target at district level in 2013 and has been sustained the situation since then. Recently, we conducted a field surveys in non-program hilly districts in Nepal where increasing number of VL cases have been persistently reported since 2000. A house-to-house survey in 14 villages from eight hilly districts documented retrospectively 54 cases of VL, predominantly males, mostly pediatric cases who were reported in the last five years. Anti-Leishmania antibodies were found in 22/23 past-VL cases, in 40/416 9.6% persons without VL and in 12/155 7.7% domestic animals. An age- and sex-matched case-control study showed that exposure to known VL-endemic areas was no risk factor for VL, but having a VL case in the neighborhood was. SSU-rDNA PCR for Leishmania sp. was positive in 24 (5%) of the human, in 18 (12%) of the animal samples and in 16 (14%) bloodfed female Phlebotomus argentipes sand flies. L. donovani was confirmed in two asymptomatic individuals and in one sand fly through hsp70-based sequencing. This study proves that there is indeed ongoing local transmission of Leishmania donovani in areas at an altitude above 600 meters, districts considered higher to non-endemic for VL. This geographical expansion of cases and ongoing local transmission could challenge the aim of the VL elimination program in Nepal. Hence, policy makers should give a high priority in expanding active surveillance and control activities to achieve the realistic goal.

5171

BEHAVIORAL INTERACTIONS OF BED BUGS WITH LONG-LASTING PYRETHROID-TREATED BED NETS: CHALLENGES FOR VECTOR CONTROL

Christopher Hayes, Coby Schal
North Carolina State University, Raleigh, NC, United States

Long-lasting insecticide-treated nets (LLINs) have historically been, and remain, one of the most commonly used vector control tools in the campaign against malaria. The emergence of pyrethroid resistant bed bugs in malaria endemic communities and failure to control infestations have been suggested to interfere with the effective use of LLINs. Therefore, the behavioral interactions of bed bugs with commonly used bed nets should be better understood. To investigate the interactions between bed bugs (Cimex lectularius) and LLINs, insecticide-susceptible and pyrethroid-resistant bed bugs were challenged to pass through two

commonly used LLINs in two behavioral assays. We found a significant impact of deltamethrin-treated nets on blood-meal- and aggregation-seeking behaviors of susceptible bed bugs, and no impact of treated nets on resistant bed bugs. Commonly used new LLINs failed to prevent the passage of susceptible and pyrethroid-resistant bed bugs in host-seeking and aggregation-seeking bioassays, resulting in overall low mortality. For the first time, we have shown the strong potential of LLINs to select for resistant non-target pests, and so their potential role in stalling malaria control programs should be further investigated.

5172

ISOLATION OF MICROSATELLITE LOCI FROM THE GENOME OF PHLEBOTOMUS ARGENTIPES, THE MAJOR VECTOR OF LEISHMANIASIS IN SRI LANKA: A PRELIMINARY STUDY

Sanduni D. Gunarathne[1], Nissanka K. De Silva[2], Nadira D. Karunaweera[1]

[1]Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka, [2]Center For Biotechnology, Department of Zoology, Faculty of Applied Sciences, University of Sri Jayawardhanapura, Nugegoda, Sri Lanka

The microsatellite markers are promising because of their high polymorphism rate, high abundance, and wide distribution throughout the genome. However, microsatellite markers have not been reported for the sandfly species Phlebotomus argentipes, possibly due to the low abundance in the genome and/or difficulty in isolation. The present study aimed to identify di- or tri-nucleotide microsatellites in P.argentipes. Whole genomic DNA was extracted from a pool of 60 sand flies, then about 9 µg were digested with RsaI restriction enzyme, and adaptors were ligated into the digested DNA. Size selection of the adaptor-ligated DNA was done using running DNA in 1.8% low melting agarose gel, followed by excising the 200-1000 bp range from the smear and recovering the DNA fragments. A PCR evaluated the success of the adaptor ligation to the digested DNA. The DNA fragments were hybridized with 3'-biotin-labeled (GT)12 oligonucleotide and captured using streptavidin-coated magnetic beads. The enriched DNA fragments were recovered by differential stringency washes and amplified by PCR. Cleaned PCR products were ligated into pGEM-T vector, then transformed into Escherichia coli JM109 competent cells and plated onto LB/ampicillin/IPTG/X-gal media. White colonies were used to construct the library which was further screened by PCR amplification. The clones giving two amplified bands were sequenced to confirm the presence of the microsatellite. More than 100 transformants were obtained from the blue/white screening and few of them have been screened by PCR. A total of 12 transformants were shown double bands and one transformant was shown an imperfect (TG) 6 microsatellite loci. In conclusion, the isolation procedure used in this study was successful, but the rest of the transformants should be screened to select a few microsatellite loci. In further studies, polymorphisms have to be evaluated by amplifying the microsatellite sequences using different subsets of P.argentipes with designated primers. This study would expand the knowledge related to the microsatellite markers in P.argentipes and might be helpful in population genetics studies.

5173

SPECIES COMPOSITION, ACARICIDE RESISTANCE IN AMBLYOMMA VARIEGATUM TICK SPECIES: KNOWLEDGE, ATTITUDE, AND PRACTICES OF LIVESTOCK OWNERS IN DIFFERENT ECOLOGICAL ZONES OF GHANA

Jane Ansah-Owusu[1], Christopher Tawiah-Mensah[1], Seth Offei Addo[1], John Arko-Mensah[2], Jewelna Akorli[1], Samuel Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Legon, Ghana, [2]School of Public Health, University of Ghana, Accra, Ghana

Acaricide failure on cattle has been on the rise globally. In Ghana, acaricides are still used to control ticks although some studies have identified acaricide resistance in ticks and reports the inappropriate use of acaricides. The aim of this study was to determine the distribution of tick species infesting livestock, assess the knowledge, attitude, and practices (KAP) of livestock owners and evaluate the resistance status of larval tick populations to some acaricides used in Ghana. This study was a cross-sectional study and tick populations evaluated in this study were collected from different cattle farms in the guinea savannah, transitional zone, deciduous forest and coastal savannah ecological zones from May to September 2022. Larval packet test was used to evaluate resistance status of Rhipicephalus ticks at discriminating dose (DD), half the discriminating dose (0.5DD) and twice the discriminating dose(2xDD) of three classes of acaricides; cypermethrin, amiraz and chlorpyrifos representing the pyrethroid, amidine and organophosphate groups respectively. The WHO criteria was used for determining the acaricide resistance status of the ticks. Statistical analysis was done using Microsoft Excel 2019 and Stata version 13.0. A total of 1022 ticks of three major genera; Amblyomma (519/1022), Hyalomma sp (136/1022) and Rhipicephalus species (367/1022). Out of the total number of ticks collected, Amblyomma variegatum constituted, 51%, followed by Rhipicephalus boophilus and sanguineus, 36%, Hyalomma rufipes and truncatum, 13%. Amblyomma variegatum was the most dominant species with a representation of 51% and also the most abundant in the different ecological zones, except for the Coastal savanna where Rhipicephalus was the most abundant species with a representation of 71% out of all the ticks collected in that zone. The study showed that Amblyomma variegatum were susceptible to cypermethrin, amiraz and chlorpyrifos acaricides and most farmers employed acaricidal control for treatment of their livestock during tick infestations.

5174

PHLEBOTOMINE SANDFLY SPECIES FROM OLD AND NEW LEISHMANIASIS FOCI OF COLOMBIA

Eduar E. Bejarano[1], Suljey Cochero[1], Matilde Rivero[1], Dina Guevara[1], Melissa Cárdenas[1], Elis Contreras[1], Aura Anaya[1], Luis Urango[2], Maria F. Yasnot[2], Liris Yepes[3], Doris Gómez[3], Luis E. Paternina[1]

[1]Universidad de Sucre, Sincelejo, Colombia, [2]Universidad de Córdoba, Montería, Colombia, [3]Universidad de Cartagena, Cartagena, Colombia

Leishmaniasis is a neglected tropical disease endemic in rural as well as urban areas of northern Colombia, which affects mainly the poorest communities; where cutaneous and visceral leishmaniasis are the prevalent clinical forms of the disease. Despite of the above, the sandfly fauna is still poorly known in several leishmaniasis foci of the north of Colombia. Even more important is the appearance of new leishmaniasis transmission foci during the last years. The aim of this work was to identify the sandfly species from old and new leishmaniasis foci of the north of Colombia. Phlebotomines were collected in ten localities of the Departments of Córdoba, Bolívar, Sucre, Cesar, and La Guajira, from 18:00 to 06:00 hours, by using CDC light traps installed in intra, peri and extra-domestic environments. Sandflies were morphologically identified up to the level of species using standard taxonomic keys for New World's sandflies. An epidemiological survey, including the characteristics of the dwellings and their surrounding area, was conducted through a mobile application developed for the study. Seventeen sandfly species were taxonomically identified, including Lutzomyia evansi, L. longipalpis, L. nuneztovari, L. shannoni, L. gomezi, L. panamensis, L. dubitans, L. rangeliana, L. punctigeniculata, L. cayennensis cayennensis, L. micropyga, L. atroclavata, L. carpenteri, L. sp. (series townsendi), L. venezuelensis, Helcocyrtomyia sp., and L. trinidadensis. New locality records are provided for the Colombian sandflies, including recognized vectors of Leishmania spp.

5175

NATION-WIDE VECTOR SURVEILLANCE OF CHAGAS DISEASE IN EL SALVADOR, 2018-2020

Yuko Nitahara[1], Marvin Stanley Rodríguez[2], Yu Nakagama[1], Katherine Candray[1], Junko Nakajima-Shimada[3], Carmen Elena Arias[4], Yasutoshi Kido[1]

[1]Osaka Metropolitan University, OSAKA, Japan, [2]Centro de Investigacion y Desarrollo en Salud, San Salvador, El Salvador, [3]Gunma Univeristy, Gunma, Japan, [4]Centro Nacional de Investigaciones Cientifcas de El Salvador, San Salvador, El Salvador

Chagas disease, caused by the infection of Trypanosoma cruzi, is one of the most serious health issues in Latin American countries. In many endemic countries, infected triatomine bugs are considered majorly responsible for the persistent T. cruzi transmission. However, the up-to-date vector burden has not been evaluated thoroughly due to the cessation of active vector surveillance in the Central American region. Our study focused on updating the risk of vector-borne T. cruzi infection in one of the most Chagas-endemic countries in the region. Nation-wide vector surveillance was performed by conducting house-to-house visits in the domestic environment of El Salvador. Houses were inspected by experienced surveyors for the infestation of vector insects. Infection for T. cruzi was evaluated by microscopic examination of insects' feces, followed by a species confirmation using PCR. As a result, we identified 1529 Triatoma dimidiata from all fourteen departments of El Salvador between the years of 2018 and 2020. No other vector species were captured in this study. Microscopic examination revealed 153 specimens out of 1529 (10.0%) positive for T. cruzi infection, which was confirmed by PCR molecular diagnosis. Geographically, higher infection rates for T. cruzi in T. dimidiata were found in departments sporadically placed across the country. These insights suggested the presence of high-risk areas of Chagas disease transmission in the region.

5176

EVOLUTION OF INSECTICIDE RESISTANCE OF ANOPHELES GAMBIAE SENSU LATO AND AN. FUNESTUS SENSU LATO IN WESTERN KENYA FROM THE YEARS OF 2019-2022

Elizabeth Ayoma[1], Celestine Wekesa[1], Benjamin Otieno[1], Amos Webale[1], Alphonce Owino[1], Edward Esalimba[1], Daisy Abongo[1], Solomon Karoki[2], Ismail Abbey[2], Lenson Kariuki[2], Charles Chege[2], John E. Gimnig[3], Daniel Wacira[4], Mildred Shieshia[4], Charity Ngaruro[5], Rodaly Muthoni[1], Matthew Kirby[5], Evelyn Olanga[1], Sheila B. Ogoma[5]

[1]Presidential Malaria Initiative, Kinga Malaria, Abt Associates, Kisumu, Kenya, [2]Division of National Malaria Program, Ministry of Health, Nairobi, Kenya, [3]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention., Atlanta, GA, United States, [4]U.S. President's Malaria Initiative, USAID, Nairobi, Kenya, [5]VectorLink project, Abt Associates, Inc., Rockville, MD, United States

Insecticide resistance is a major threat to malaria vector control efforts. Understanding insecticide resistance is crucial for developing effective resistance management strategies and informing the selection and deployment of vector control interventions. The aim of this study was to evaluate the evolution of resistance and mechanisms underlying resistance to pyrethroids, organophosphates and neonicotinoids in malaria mosquito populations in western Kenya. Larvae were collected from Busia, Siaya, and Homa Bay counties in 2019, 2020 and 2022. Susceptibility tube tests, synergist PBO bioassays, and intensity CDC bottle assays were carried out on adult Anopheles gambiae s.l. Five insecticides (deltamethrin, permethrin, alpha-cypermethrin, pirimiphos-methyl, clothianidin) were evaluated. The presence of target site mutation conferring knockdown resistance was investigated using a TaqMan assay. The level of resistance was shown to increase over time for deltamethrin across the 3 sites, with average change in mortality at 46%, 56% and 58% in Busia, Homa Bay and Siaya, respectively. Similar trends were also recorded for permethrin across the sites. Pre-exposure to piperonyl butoxide synergist (PBO) for An. gambiae s.l prior to exposure to pyrethroids significantly increased mortalities but did not fully restore susceptibility. Resistance intensity was low in Homa Bay (>98% mortality at 5X), moderate in Siaya (>98% mortality at 10×) and high in Busia (<98% mortality at 10×). Low to moderate allelic frequencies were detected ranging from as low as 2% to as high as 74% across the sites with 1014S having the highest frequencies of 74% and 61% for An. gambiae s.s. and 8% and 50 % for An. arabiensis in 2021 and 2022 respectively for Busia. Susceptibility to pirimiphos-methyl and clothianidin was recorded across all the sites across all years. The spread of insecticide resistance has significant implications for malaria control in western Kenya. To address this challenge the deployment of new tools including ITNs with dual active ingredients or new class of insecticide is encouraged.

5177

PHENOTYPIC AND MOLECULAR ASSAYS CONFIRM PUTATIVE PYRETHROID RESISTANCE IN ANOPHELES ALBIMANUS IN MALARIA ELIMINATION SETTINGS IN HONDURAS

Denis Escobar[1], Osman Archaga[1], Oscar Urrutia[2], Rosa Elena Mejía[3], Lucrecia Vizcaino[4], Audrey Lenhart[4], Gustavo Fontecha[1]

[1]Microbiology Research Institute, Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, [2]Secretaria de Salud Honduras, Tegucigalpa, Honduras, [3]Organización Panamericana de la Salud – Oficina Honduras, Tegucigalpa, Honduras, [4]Entomology Branch, Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Vector control continues to be the principal strategy for malaria elimination worldwide. In Honduras, control relies on pyrethroid insecticide-treated bednets (ITNs) and indoor residual spraying (IRS) with carbamates. Even with adequate vector control coverage, malaria cases have risen from 330 to 1550 cases per year, between 2019 and 2021. Phenotypic insecticide resistance has been detected previously, and given those findings, we carried out an assessment of key insecticide resistance target-site mechanisms in vector populations from the main endemic areas of the country. Wild-caught adult anophelines were collected in eight localities across six malaria-endemic departments in Honduras, during 2021. Using CDC bottle bioassays, susceptibility to diagnostic doses of deltamethrin, permethrin, and bendiocarb were carried out. PCR and sequencing were used to identify mutations at positions 995 in the VGSC gene and 280 in the Ace-1 gene. Our findings revealed that An. albimanus in three sites were resistant to at least one pyrethroid. Individuals from Gracias a Dios, the main endemic region, were susceptible to deltamethrin. All populations were susceptible to bendiocarb. Populations from Yoro, Comayagua and Olancho reported mortalities ranging from 48 to 89% (permethrin) and 62 to 88% (deltamethrin). Two genotypes (TGT and TTC) equivalent to mutation L995F (16%) and L995C (30%) were detected at the VGSC in 4 of 8 localities. Comayagua showed the highest frequency for L995C (65%), and Santa Rita for L995F (77%). No mutations were found at the Ace-1 gene. A substantial number (44/184) of potential heterozygotes (TNN) for kdr were detected. This is the first report detecting two target-site mutations on the VGSC gene associated with PY resistance in malaria vectors from Honduras, with the L995C allele as the most frequent mutation across the populations screened. Further analysis will clarify the frequency of heterozygotes. The nascent pyrethroid resistance reported here should inform the choice of vector control products from alternative insecticide classes, in order to allow for proactive resistance mitigation and management

THE GENOMICS BEHIND INSECTICIDE RESISTANCE IN ANOPHELES MOSQUITOES FROM THE BIJAGÓS ARCHIPELAGO

Sophie Moss[1], Elizabeth Pretorius[1], Sainey Ceesay[2], Robert Jones[1], Jody Phelan[1], Emma Collins[1], Taane G. Clark[1], Anna Last[1], Susana Campino[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Medical Research Council, The Gambia (MRCG), Serrekunda, Gambia

Evolving insecticide resistance threatens the efficacy of vector control interventions. In turn, this threatens the control of all vector-borne diseases, including malaria. The Bijagós Archipelago is situated off the coast of Guinea-Bissau, West Africa, and is endemic for malaria. The major vectors for malaria in the Bijagós are Anopheles gambiae in the rainy season, and An. melas in the dry season. The mainstay of malaria control in the Bijagós is Long Lasting Insecticide treated Nets. The WHO recommend monitoring insecticide resistance to inform evidence-based vector control interventions. This study investigated the status of insecticide resistance in mosquito vectors across the Bijagós archipelago in 2019 and 2022 using both phenotypic assays and molecular monitoring of resistance markers. WHO bottle bioassays were used to assess phenotypic resistance to deltamethrin, and molecular monitoring was used to investigate the frequency of genomic markers of insecticide resistance to a broad range of insecticides. Molecular monitoring was conducted using high-throughput custom-targeted amplicon sequencing. Collected mosquitoes included a high proportion of An. gambiae/coluzzii hybrids (28%). This study revealed phenotypic resistance to discriminating concentrations of deltamethrin in 50% of the mosquitoes assayed. Whole Genome Sequencing was employed to investigate signatures of directional selection associated with deltamethrin resistance, by comparing genomic diversity in resistant and susceptible mosquitoes. Investigation of molecular markers revealed the presence of mutations associated with pyrethroid resistance in the Voltage Gated Sodium Channel (VGSC) gene (kdr mutations) L995F, N1570Y and A1746S. Mutations in the GSTE2 gene associated with resistance to organophosphates and carbamates were also identified, including F120L and L119V, as well as the RDL A296G mutation associated with resistance to dieldrin and fipronil.

5179

PROFILING OF INSECTICIDE RESISTANCE, MICROBIOME AND PATHOGEN PREVALENCE IN AEDES AEGYPTI IN PUERTO RICO

Emma Louise Collins[1], Joanelis Medina Quintana[2], Luis Marrero Ortiz[2], Julieanne Miranda-Bermúdez[2], Taane Clarke[1], Grayson Brown[2], Susana Campino[1]

[1]London School of Hygiene and Tropical Medicine, LONDON, United Kingdom, [2]Puerto Rico Vector Control Unit, Puerto Rico Science, Technology and Research Trust, San Juan, PR, United States

Puerto Rico suffers from the circulation of arboviruses, including dengue, Zika and chikungunya, transmitted by the Aedes aegypti mosquito. The predominant control strategies across the island are breeding habitat removal, larviciding and spatial spraying in response to outbreaks. This study aims to characterise the Ae. aegypti population in Puerto Rico in terms of phenotypic and molecular insecticide resistance, microbiome composition and pathogen prevalence, as well as assessing associations between these factors. Ae. aegypti eggs were collected using ovitraps from 2 sites (Bayamón and San Juan) and reared to adults. These adults were subjected to testing against deltamethrin and malathion at three concentrations. A target amplicon sequencing approach was used to identify genetic variants such as single nucleotide polymorphisms SNPs and insertions/deletions associated with insecticide resistance and identify Wolbachia in the microbiome. We found considerable resistance in both sites to one- and five-times diagnostic dose of deltamethrin and one- and three-times diagnostic dose of malathion. Mortality at one diagnostic dose was under 25% for deltamethrin and under 40% for malathion in mosquitoes from both sites. Molecular assays revealed mutations in insecticide resistance relevant genes including; VGSC, RDL, ACE and GSTE2, including a novel mutation not previously described in Ae. aegypti, but that has been associated with resistance in other insects. Neither Wolbachia nor arboviruses were identified in the samples we screened. Understanding insecticide resistance is vitally important to facilitate the best possible control strategies for arboviral disease. Here we show that this Ae. aegypti population has high levels of resistance to the pyrethroid deltamethrin and the organophosphate, malathion. Insecticide resistance data should be used to inform the future selection of compounds used in larvicides and insecticide spraying for vector control.

EVALUATION OF THE SUSCEPTIBILITY OF ANOPHELES FUNESTUS POPULATIONS IN THE CENTRE, CENTRE-WEST AND SOUTH-WEST REGIONS OF BURKINA FASO

Bénoît Sanon[1], Antoine Sanou[1], Hyacinthe Toe[2], Michel Tapsoba[1], Soumanaba Zongo[1], Salimata Oueraogo[1], Sakinata Yameogo[1], Inoussa Toe[3], Moussa W. Guelbeogo[1]

[1]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [2]Université Joseph Ki Zerbo, Ouagadougou, Burkina Faso, [3]Université Nazi Boni, Ouagadougou, Burkina Faso

In recent years, insecticide resistance in the main malaria vectors has intensified in sub-Saharan Africa. This poses a threat to the effectiveness of insecticide-based vector control interventions. In Burkina Faso the main malaria vectors are members of the gambiae complex and the funestus group. Monitoring the susceptibility level of all vectors is necessary to adapt control strategies. The aim of this study was to update on the insecticide susceptibility profile of Anopheles funestus populations. Indoor resting blood-feed female mosquitoes were collected between September and November 2021 in Naaba-Zana in the Centre, La in the Centre-West and Sibera in the South-West, three villages in Burkina Faso. Female members of the An. funestus s.l. group were oviposited to generate F1. Insecticide tests were performed on the F1 progeny to assess the susceptibility profile of this vector to three classes of insecticides (pyrethroids, carbamates and organophosphates) using the WHO cylindrical-tube test guidelines. The specific composition of the funestus group members, the sporozoite infection rate and the presence of the L119F-GSTe2 gene were investigated. An. funestus s.s. was the only species of the funestus group present in all three localities. The sporozoite infection rate was 6.47%. Anopheles funestus s.s. was resistant to deltamethrin in all the three localities with mortality rates being 21.24%, 35.43% and 65.24% respectively in Naaba-Zana, La and Sibera. However, the population at the La site was resistant to bendiocarb but susceptible to pyrimiphos-methyl. The frequency of the L119F-GSTe2 mutation conferring resistance to DDT and pyrethroids was overall 24.30%. These results suggest that resistance to pyrethroids and carbamates in An. funestus in Burkina Faso could pose a threat to the effectiveness of operational insecticide-based vector control tools.

MONITORING INSECTICIDE RESISTANCE STATUS OF AEDES AEGYPTI AND AE ALBOPICTUS POPULATIONS IN FIVE LOCAL GOVERNMENT AREAS IN LAGOS STATE, NIGERIA

Reham A. TagEldin[1], Hala S. Thabet[1], Samuel O. Babalola[2], Oyeniyi Tolulope[2], Olanrewaju Adekunle[2], Oluwakemi Adetunji[2], Romoke Izekor[2], Olagundoye Olalekan[2], Ahmed Omotayo[2], Olakiigbe Abiodun[2], Taye Adekeye[2], Chidinma Isaac[2], Phillip O. Oyale[3], Adedapo O. Adeogun[2], James F. Harwood[1]

[1]U.S. Naval Medical Research Unit-3 (NAMRU-3), Cairo detachment, Egypt, [2]Public Health and Epidemiology Department, Nigerian Institute of Medical Research, Lagos State, Nigeria, [3]Integrated Vector Management Department, National Malaria Elimination Program, Abuja, Nigeria

Aedes aegypti and Ae. albopictus, the principal vectors of dengue, Zika, and chikungunya viruses, have progressively started to develop resistance against most of the currently used insecticides. This increase in resistant populations makes management crucial to the design of effective disease control. Thus, this study was carried out in Lagos State to determine the insecticide susceptibility status of Aedes species. Bioassays were performed on Aedes species, according to their abundance, in five Local Government Areas (LGAs) between July and September 2022. Aedes larvae and pupae were collected from tires, plastic containers, and abandoned water closets. Ae. aegypti were collected from three LGAs (Ibeju Lekki, Yaba, and Alimoso), while Ae. albopictus were found in the other two LGAs (Ikorodu and Somolu). Immature stages were reared to the adult stage at the insectary of the Nigerian Institute of Medical Research (NIMR). Three to five-day-old sugar-fed females were exposed to four classes of insecticides according to the standard WHO protocol: organochlorines (4% DDT); carbamates (4% bendiocarb); pyrethroids (0.75% permethrin & 0.05% deltamethrin); and organophosphates (5% malathion). Results revealed that the collected populations of Ae. aegypti were susceptible to bendiocarb and malathion (100% mortality to both insecticides), but resistant to permethrin (mortality from Ibeju Lekki was 42%, Yaba was 52%, and Alimoso was 50%), deltamethrin (mortality from Ibeju Lekki 57%, Yaba 59%, and Alimoso 52%) and resistant to DDT (mortality from Ibeju Lekki and Yaba was 100% and Alimoso was 39%). For Aedes albopictus, the Somolu population was 100% susceptible to bendiocarb and malathion but resistant to permethrin and deltamethrin. The Ikorodu population showed 100% susceptibility to malathion and resistance to other insecticides (bendiocarb resulted in 87% mortality, permethrin resulted in 62% mortality, and deltamethrin resulted in 76% mortality). The level of detected resistance in these populations prompts the need to use alternative insecticide classes for the control of Aedes populations in this region.

5182

INSECTICIDE RESISTANCE SPECTRUM AND PREVALENCE OF L1014F KDR TYPE MUTATION IN ANOPHELES GAMBIAE S.L. IN ABIA STATE, NIGERIA

Chukwuebuka Mathias Ekedo[1], Onyinye M. Ukpai[1], Collins N. Ehisianya[1], Udoka C. Nwangwu[2], Tolulope A. Oyeniyi[3], Adedapo O. Adeogun[3]

[1]Michael Okpara University of Agriculture, Umudike, Umuahia, Nigeria, [2]Arbovirus and Vector Research Institute, Enugu State., Enugu, Nigeria, [3]Nigerian Institute of Medical Research, Lagos State, Yaba, Nigeria

Anopheles gambiae s.l. is the primary vector of malaria, a debilitating disease responsible for substantial mortality and morbidity in Sub-Saharan Africa. This study was conducted to evaluate the insecticide resistance status and frequency of L1014F kdr mutation in Anopheles gambiae [Diptera: Culicidae, Giles 1902] within Abia state, Nigeria. Immature stages of An. gambiae (s.l.) were collected from Umudike, Agalaba, and Ebem communities and reared to adulthood. Batches of twenty five sugar fed female mosquitoes, aged 3-5 days, were exposed to four types of WHO insecticide impregnated papers i.e., 4% DDT, 0.75% Permethrin, 0.1% bendiocarb, and 5% Malathion, for one hour and the mortalities were recorded after a recovery period of 24 hours. Mosquitoes were also subjected to molecular diagnosis for speciation, and genotyped for kdr type gene mutation L1014F. Anopheles gambiae (s.l.) was highly resistant to permethrin (Umudike-18.76% mortality, Agalaba-17.51%, Ebem-49.01%) and DDT (0%) in the three locations. Conversely, all the locations recorded complete susceptibility to malathion (100%). Although complete susceptibility to bendiocarb was reported from Umudike (100%) and Ebem (100%), some resistance was reported from Agalaba (87.5%). PCR analyses showed that An. gambiae (s.l.) were predominantly An. gambiae s.s. in Umudike (90%), Agalaba (67.5%)- and Ebem (67.5%), whereas the rest were An. coluzzii. Very high frequencies of the L1014F kdr mutation was observed in all locations [Umudike (1.00), Agalaba (0.98), and Ebem (0.95)]. Interestingly, mosquitoes from Agalaba that survived the 24 hours post-exposure were put in a freezer (-12°C) for about eight hours to die, but it was observed that the mosquitoes which appeared dead in the recovery tubes got resuscitated shortly after they were brought out of the freezer. The worrisome resistance to bendiocarb in Agalaba suggests existence of metabolic resistance that needs to be clarified and calls for urgent implementation of integrated vector control strategies, whereas a study on the possibility of hibernation in An. gambiae s.l. mosquito populations during cold season is suggested.

EPITHELIAL NITRATION RESPONSE TO PLASMODIUM FALCIPARUM IN INSECTICIDE RESISTANT ANOPHELES COLUZZII MOSQUITOES

Patrick Hoerner[1], Moritz Ebeling[2], Julia Maeurer[1], Victoria Ingham[1]

[1]Heidelberg University Hospital, Heidelberg, Germany, [2]Heidelberg University, Heidelberg, Germany

Insecticide-based vector control tools are the most valuable resource to fight malaria infections with insecticide treated bed nets (ITNs) accounting for almost 70% of the reductions in malaria cases between the years 2000 – 2015. Recently, progress in reducing malaria cases has stalled according to the World Malaria Report 2022; this corresponds strongly with the spread of insecticide resistance (IR). The threat is confounded by the use of relatively few insecticides in malaria control programs, highlighted by use of pyrethroids on all bed nets currently distributed. The mosquito harbours the longest-lived life stages of the parasite and offers an attractive target for interrupting the transmission cycle. Reactive oxygen species (ROS) and reactive nitrogen species (RNS) have been shown as effective mediators of the anti-plasmodial immune response in the midgut. In particular in the epithelial nitration reaction, a major barrier for parasite invasion, by attacking ookinetes. Unfortunately, in contrast to rodent malaria this response has been shown mostly ineffective for the human pathogenic parasite Plasmodium falciparum. Transcriptomic analysis of insecticide resistant Anopheles coluzzii mosquitoes from Burkina Faso indicated potential higher levels of metabolic activity, as reported previously. Such high levels may lead to increased RNS/ROS and thus differential vectorial capacity for P. falciparum. The potential for perturbance of the redox state offers exciting new avenues for the development of more effective or additional vector control tools, like attractive targeted sugar baits (ATSBs), for improved integrated vector management directly targeting parasite invasion. This study illustrates the relationship between oxidative stress, insecticide resistance and anti-plasmodial immunity. We demonstrate that the epithelial nitration response and ROS state differs between insecticide resistant and insecticide susceptible mosquitoes of the An. gambiae complex, potentially leading to differential vectorial capacity.

BREEDING WATER EFFECT ON ANOPHELES GAMBIAE SENSU LATO INSECTICIDE SUSCEPTIBILITY DURING LABORATORY COLONIZATION

Ibrahim Kwaku Gyimah, Jewelna Akorli, Godwin Kwame Amlalo, Rebecca Pwalia, Samuel Sowah Akporh, Aaron Lartey, Dominic Acquah-Baidoo, Ali Alhassan, Joannitta Joannides, Samuel Darkwa, Godwin Koffa, Akua Danquah, Samuel Kweku Dadzie

Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana

The challenge of insecticide resistance in malaria vector populations has led to the need for laboratory testing of new insecticide formulations using Anopheles gambiae s.l. mosquitoes. This study aimed to investigate how the insecticide resistance profile of laboratory-maintained mosquitoes changes after multiple generations of breeding without the selective pressures found in their natural breeding sites, mainly focusing on the effect of the larval water sources. Anopheles gambiae s.l. larvae from a known insecticide-resistant field population were bred in field, tap, or distilled water for 11 generations under standard laboratory conditions. The adult mosquitoes were then exposed to WHO discriminating insecticide dosage of several insecticides, and the detoxification activity of the population was assessed through a synergist assay with piperonyl butoxide (PBO) and pyrethroids. The enzymatic activity of the various colonies and physicochemical parameters of the different water types were also analyzed. The WHO susceptibility results showed high resistance to all insecticides (mortality ≤ 90%). However, mosquitoes bred in field water showed relatively high mortality upon synergist exposure. The An. gambiae colony bred in field water also showed higher enzymatic activity for α esterase, mixed function oxidases (MFO's), and β esterase compared to the other breeding water types (P≤ 0.05), with insensitive acetylcholinesterase (ACHE) activity remaining constant across all breeding water types. Lastly, the field water was found to be polluted based on the physicochemical parameters measured with reference to WHO guidelines. This study recommends the use of field breeding water to replicate and maintain the observed field levels of phenotype, genotype, and metabolic insecticide resistance in laboratory-reared Anopheles gambiae s.l. mosquitoes, as it outperforms and maintains all three resistant mechanisms.

NATIONWIDE ASSESSMENT OF MALARIA VECTOR SUSCEPTIBILITY TO CHLORFENAPYR, PYRIPROXYFEN, AND ALPHA-CYPERMETHRIN IN PREPARATION FOR WIDESCALE DEPLOYMENT OF NEW GENERATION NETS (INTERCEPTOR® G2 AND ROYAL GUARD®) IN BENIN

Rock Aikpon[1], Razak Ossè[2], Gil Padonou[2], cyriaque affoukou[1], Virgile Gnaguenon[3], Patrick Condo[3], Ahmed Saadani Hassani[3], Daniel Impoinvil[4], Martin Akogbéto[2]

[1]Ministry of Health Benin/ National Malaria Control Program, Cotonou, Benin, [2]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [3]US President's Malaria Initiative, US Agency for International Development, Cotonou, Benin, Cotonou, Benin, [4]U.S. President's Malaria Initiative (PMI), Entomology Branch, Division of Parasitic Disease and Malaria, U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, USA, Atlanta, GA, United States

Pyrethroid resistance is widespread in sub-Saharan Africa, including Benin, and threatens the effectiveness of pyrethroid-treated mosquito nets. To manage this generalized resistance to pyrethroids, new-generation insecticide-treated nets (NG-ITNs) with new active ingredients (AIs) have been developed. Before the deployment of NG-ITNs, it is essential to determine the sensitivity of malaria vectors to new AIs. The objective of this evaluation was to assess malaria vector susceptibility to 3 AIs (chlorfenapyr, pyriproxyfen, and alpha-cypermethrin) before the widescale deployment of Interceptor® G2 and Royal Guard® nets nationwide in Benin. The study was conducted in all 34 health zones throughout Benin. In each health zone, a simple random sample of one commune was selected using the sample function in R. Larval collections, rearing to adults, and susceptibility testing was carried out in all communes between August and December 2022 on Anopheles gambiae s.l. Standard WHO tube test was used for alpha-cypermethrin, and WHO bottle bioassay was used from chlorfenapyr and pyriproxyfen. Mosquitoes were resistant to alpha-cypermethrin with mortality rates ranging from 1% to 69%. Mosquitoes exposed to 100 µg chlorfenapyr died after 24 hours except in 3 communes where mortality rates ranged from 80% and 97%; however, mortality did reach 100% after 48 hours. For pyriproxyfen, all mosquito populations exposed to 100 µg pyriproxyfen were infertile with no eggs reaching the Christopher stage V (the majority were blocked at stage III), whereas most eggs of the same mosquito population exposed to acetone (control) reached the Christopher stages with fertility rates up to 68%. This evaluation provides key data on malaria vector susceptibility to the new AIs on NG-ITNs across Benin, suggesting that the deployment of NG-ITNs should be effective in controlling mosquitoes. However, monitoring of these AIs should continue to detect the emergence of resistance. Although chlorfenapyr was lethal and pyriproxyfen inhibited fertility, operational evaluations will help to better understand the relative efficacy of Interceptor® G2 and Royal Guard® nets.

5186

ANOPHELES GAMBIAE S.L. KNOCKDOWN RESISTANT MUTANT ALLELES AND SUSCEPTIBILITY TO INSECTICIDES IN THREE SENTINEL SITES OF ZIMBABWE

Brenda B. Makonyere[1], Trust Nyakunu[1], Tariro P. Chikava[1], Natasha Mbwana[1], Lissa Muropa[1], Petros Kawadza[1], Funel Toto[1], Trish Mharakurwa[1], Waraidzo Mvumi[1], Wietske Mushonga[1], Isaac Chikono[2], Liberty Mutasa[2], Tanatswa X. Gara[1], Charmaine R. Matimba[1], Aramu A. Makuwaza[1], Hieronymo Masendu[2], Nobert N. Mudare[1], Sungano I. Mharakurwa[1]

[1]Africa University, Mutare, Zimbabwe, [2]VectorLink Zimbabwe, Harare, Zimbabwe

Indoor residual spraying and long-lasting insecticidal nets are the mainstay malaria prevention measures in Zimbabwe. However, efficacy of the insecticides is affected by vector resistance mechanisms. Aim of this study is to assess the status of insecticide susceptibility to insecticides sprayed in malaria endemic areas. 1,929 mosquito larvae were collected in Mashonaland East province (Mudzi, Mutoko and Wedza district) from March 2020 to August 2022. The larvae were reared under insectary conditions. WHO tube and bottle bioassays were conducted and mortality rate was assessed after 24 hours. Anopheles arabiensis KGB strain was used as susceptible positive control. An. gambiae s.l specimens morphological identification and confirmatory PCR was determined previously. Further analyse to detect kdr and ACE1R alleles were done in previously reported studies. 5.6% were An. arabiensis, 0.73% An. gambiae ss, 0.47 % An. merus and 93% An. quadriannulatus 100% mortality after 24 hrs exposure was recorded in Wedza. Kdr to clothianidin was recorded 75% in Mutoko and 86.6% mortality rate in Mudzi. PCR showed that 1.44% An. quadriannulatus was resistant to deltamethrin, DDT, pirimiphos-methyl and clothianidin in Mutoko and Mudzi. All An. gambiae ss and An. merus were susceptible whereas 2.04% An. arabiensis species were resistant to deltamethrin in Mutoko. L1014S allele was found in Mudzi 0.01% and Mutoko 0.5%, whereas L1014F allele was 0.4% Mudzi and 0.7% Mutoko. ACE1 resistance was present in Mutoko 1.04% and 0.3% in Mudzi. Deltamethrin insecticide was associated with L1014S mutant allele (p=0.01). DDT and pirimiphos-methyl were associated with L1014F mutant allele (P=0.01). ACE1R was associated with clothianidin and deltamethrin in Mutoko and Mudzi (P=0.01). An. gambiae species were susceptible to alpha-cypermethrin, chlorfenapyr and permethrin insecticides, thus using these insecticides in the study sites is recommended. Furthermore, results have identified the need for new approaches for monitoring insecticide resistance studies since larval collections can be dominated by non-vectors.

5187

IDENTIFICATION AND INSECTICIDE RESISTANCE PROFILE OF ANOPHELES AZEVEDOI (RIBEIRO, 1969) IN LUANDA PROVINCE, ANGOLA: IMPLICATIONS FOR VECTOR CONTROL

Catia J. Teixeira Marques[1], Vicente Chipepa[1], Anya Fedorova[1], Alice Sutcliffe[2], José Franco Martins[3], Cani P. Jorge[3], Melissa Yoshimizu[4], Joana Do Rosario[5], Kelley Ambrose[6], Mohamed Bayoh[6], Paula Marcet[2]

[1]U.S. President's Malaria Initiative (PMI) VectorLink Project, Population Services International Angola, Luanda, Angola, [2]Entomology Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Angola National Malaria Control Program, Luanda, Angola, [4]PMI, USAID, Washington DC, WA, United States, [5]PMI, USAID, Luanda, Angola, [6]PMI VectorLink Project, Abt Associates, Rockville, MD, MD, United States

In collaboration with the National Malaria Control Program, the U.S. President's Malaria Initiative VectorLink project re-established entomological activities in Angola in 2019 through routine assessments of species composition and susceptibility to relevant insecticides of the primary malaria vector species (Anopheles gambiae s.l. and An.funestus s.l). In Luanda Province, the most abundant larval-reared specimens collected for insecticide susceptibility tests were initially morphologically identified as a species of the An. funestus s.l. group. A subset of specimens were analyzed at the CDC Entomology Branch, where morphological and molecular analyses determined they were An. azevedoi. This identification was further confirmed by the US National Museum of Natural History (Smithsonian Institution) where voucher specimens from these collections were indexed. Sequences for the ITS2 and CO1 barcoding genes were produced and reported to GenBank for the first time. Retroactive DNA sequence analysis of archived samples detected An. azevedoi among larval collections in the provinces of Namibe and Benguela, which had been incorrectly reported as An. gambiae s.l.Since 2021, An. azevedoi larvae have been collected in two villages in Luanda Province. WHO insecticide susceptibility assays conducted in 2021 found the species to be resistant to deltamethrin and alpha-cypermethrin (mortality of 56% and 68%, respectively), with pre-exposure to PBO fully restoring susceptibility to both insecticides. Populations were fully susceptible to chlorfenapyr. A sub-sample of adult An. azevedoi collected through indoor CDC light traps underwent blood meal analysis and 9 of 26 had fed on humans. No Plasmodium falciparum sporozoites were detected in this set.These findings show that An. azevedoi is a prevalent species in several regions of Angola. It has been historically incorrectly identified, is resistant to pyrethroids, is present inside houses, and feeds upon humans. Continued entomological monitoring, sporozoite assays, and research on this species is recommended to understand its role in malaria transmission in Angola.

Due to widespread pyrethroid resistance, entomological surveillance is an integral part of Nigeria's national insecticide resistance management plan and supports sustainable malaria vector control decisions. We examined the programmatic implications of long-term monitoring of pyrethroid resistance intensity in Nigeria. Intensity assay data from mosquitoes exposed to 5X and 10X permethrin, deltamethrin, and alpha-cypermethrin collected in five ecological zones between 2019-2022 were assessed. Monitoring sites with full resistance intensity data for three out of four years (75%) for all three pyrethroids tested were included in the analysis. An. gambiae s.l. mosquitoes from two sites—Akwa Ibom (mangrove/rainforest ecozone) and Plateau (Guinea savannah ecozone)—reported low resistance intensity (mortality>98% at 5X the diagnostic dose) to alpha-cypermethrin. Low resistance intensity to deltamethrin was reported only in Plateau (Guinea Savannah ecozone). Low permethrin resistance intensity was more widespread (4/5 ecozones), and the proportion of sites reporting increased over time: 44% to 100% in Sahel, 50-100% in Guinea Savannah, 66-100% in Mangrove/Rainforest, and 83-100% in Rainforest/Guinea Savannah. Moderate resistance intensity (mortality>98% at 10X) to permethrin was observed in all ecozones and the proportion of sites reporting this increased from Oyo in the Rainforest/Guinea Savannah (0-16%), Plateau in the Guinea Savannah (0-33%), Kebbi in the Sahel savannah (33.5-55.6%), Akwa Ibom and Cross Rivers in the Mangrove (16.7-100%), and Ebonyi in the Rainforest (50-100%). A high resistance intensity (<98% mortality at 10X) to permethrin was observed in An. gambiae s.l. mosquitoes from 3/5 ecozones and increased from the Plateau in Guinea Savannah (0-16%), Ebonyi in the Rainforest (44-100%) and Akwa Ibom in the Mangrove (83.3-100%). Compared to permethrin, resistance intensity to alpha-cypermethrin and deltamethrin was still low and only established in two ecozones. This assessment provides additional information to Nigeria's National Malaria Elimination Program on the need for new types of ITNs in Nigeria.

5189

HIGH ENTOMOLOGICAL INOCULATION RATE OF ANOPHELES COUSTANI IN THE MALARIA ELIMINATION SETTINGS OF DEMBIYA DISTRICT, NORTH-WESTERN ETHIOPIA

Mihretu Tarekegn Nigatu

Woldia University, Woldia, Ethiopia

Despite the progress in scaling up the intervention tools in Ethiopia, malaria is still a major health problem. Therefore, a continuous monitoring of the local vector behavior & ecology is relevant to design evidence based malaria control strategies. This study investigated the species composition & the biting & resting behaviours of Anopheles mosquitoes in selected localities of Dembiya District. Adult Anopheles mosquitoes were sampled indoors & outdoors from June 2018 to May 2019 by using CDC light traps, pyrethrum spray catches, artificial pit shelters, & mouth aspirators. Anopheles mosquitoes were identified to the species level. Their blood source & Plasmodium sporozoite infections were determined using an Enzyme-linked immunosorbent assay. PCR was used for identification of sibling species of An. gambiae s.l. Anopheles mosquitoes belonging to 11 species were identified from 2,055 collected mosquito specimens. Anopheles pharoensis & An. arabiensis were the dominant species in both Guramba Bata & Arebiya study sites. The CDC light traps caught the highest number of Anopheles mosquitoes in both study sites. The density of outdoor host-seeking & resting Anopheles mosquitoes were higher outdoors than indoors ($P \geq 0.05$). The human blood indexes (HBI) of indoor and outdoor host-seeking An. arabiensis were 17.4% & 15.3%, respectively. The entomological inoculation rate (EIR) of outdoor host-seeking An. arabiensis was 4.7 infective bites/person/year. Additionally, the outdoor EIR of host-seeking An. coustani was 25.7ib/p/year. In conclusion, the indoor & outdoor density of host-seeking & resting Anopheles mosquitoes were comparably high in the Dembiya district. This contrast with the fact

that the area is known for the long-term implementation of vector control strategies. Therefore, re-evaluating vector control strategies considering vector & host behaviour is mandatory to eliminate malaria in the study area. Anopheles pharoensis, An. coustani, and An. squamosus were positive for Plasmodium circum-sporozoite protein, which urges further investigations to substantiate their vectoral role.

NATURAL INFECTION OF NYSSORHYNCHUS DARLINGI AND NY. BENARROCHI B WITH PLASMODIUM DURING THE DRY SEASON IN THE UNDERSTUDIED LOW TRANSMISSION SETTING OF DATEM DEL MARAÑON PROVINCE, AMAZONIAN PERU

Jan E. Conn[1], Sara A. Bickersmith[1], Marlon P. Saavedra[2], Juliana A. Morales[3], Freddy Alava[4], Gloria A. Rodriguez[5], Clara R. del Aguila Morante[6], Carlos G. Tong[1], Carlos Alvarez-Antonio[7], Jesus M. Daza Huanahui[7], Joseph M. Vinetz[8], Dionicia Gamboa[9]

[1]Wadsworth Center, New York State Department of Health, Slingerlands, NY, United States, [2]Universidad Peruana Cayetano Heredia, Laboratorio de Investigación y Desarrollo, Iquitos, Peru, [3]Universidad Peruana Cayetano Heredia - Laboratorio de Investigación y Desarrollo, Iquitos, Peru, [4]Ministry of Health, Iquitos, Peru, [5]Laboratorio de Salud Publica-Gerencia Regional de Salud de Loreto, Iquitos, Peru, [6]5Laboratorio de Salud Publica-Gerencia Regional de Salud de Loreto, Iquitos, Peru, [7]Gerencia Regional de Salud de Loreto, Iquitos, Peru, [8]Yale School of Medicine - Department of Internal Medicine, New Haven, CT, United States, [9]Universidad Peruana Cayetano Heredia - Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Lima, Peru

The persistence of malaria hotspots in Datem del Marañon Province, Peru, prompted vector control units at the Ministry of Health, Loreto Department, to collaborate with the Amazon International Centers of Excellence for Malaria Research to identify the main vectors in several riverine villages that had Annual Parasite Incidences (API) >15 in 2018-2019. Anophelinae were collected indoors and outdoors for two 12-hr nights/community during the dry season in 2019 using Human Landing Catch. We identified four species: Nyssorhynchus benarrochi B, N. darlingi, N. triannulatus and Anopheles mattogrossensis. The most abundant, Ny. benarrochi B, accounted for 96% of the total (7550/7844) of which 62% were captured outdoors (4826/7844). Nine mosquitoes, 4 Ny. benarrochi B and 5 Ny. darlingi, were infected by Plasmodium falciparum, P. vivax or both. Human Biting Rates ranged from 0.5-592.8 bites per person per hour for Ny. benarrochi B and 0.5-32.0 for Ny. darlingi, with EIR values as high as 0.75 infective bites per night for Ny. benarrochi B and 0.50 for Ny. darlingi. These data demonstrate the risk of malaria transmission by both species even during the dry season in villages in multiple watersheds in Datem del Marañon province.

HOUSES IMPROVING AS A SUPPLEMENTAL INTERVENTION TOOLS FOR REDUCING INDOOR VECTOR DENSITIES AND MALARIA PREVALENCE IN EMANA, CENTER CAMEROON

Yacouba Poumachu[1], Joko Tamoufe[1], Kouamendjouo Djilla[1], Viviane Ongbassonbem[2], Awono A. Parfait[1], Timoleon O. Tchuinkam[3], Amelia I. Ficham[4], Ella I. Green[4], Tamar I. Ghosh[4], Cyrille Ndo[2]

[1]Central African Organization for Endemic Disease Control, Yaounde, Cameroon, [2]Center for Research in Infectious Diseases, Yaounde, Cameroon, [3]University of Dschang, Dschang, Cameroon, [4]Royal Society of Tropical Medicine and Hygiene, London,UK, United Kingdom

Improvement of typical rural houses can effectively reduce indoor vector densities and consequently malaria transmission. We assessed this supplemental control effects in a MILDA low coverage area of center Cameroon. 16 houses were firstly selected based on their indoor density of resting malaria vectors. Half of them randomly chosen for eaves screens (experimental) with fibreglass coated wire mesh and half left unscreened (control). Entomological baseline were collected monthly in both groups. Outdoors and indoors adults mosquitoes were sampling for entomological data collection in each houses using Human Landing Catch (HLC). Malaria prevalence surveys were conducted after mosquitoes sampling in both groups. A total of 300 mosquitoes were collected over six months period using HLC in 16 houses (mean mosquitoes =18.75). Among Anopheles funestus, 63.9% were unfed, 32.9% blood fed, 0.39% gravid and 1.56% half gravid females. 17.7% of An. gambiae were unfed and 82.2% blood fed. More indoor adult mosquitoes were collected in the control (n=74) than experimental houses (n=56). Parasitological surveys results to relatively low malaria parasite prevalence rates in screened houses compared to the control houses. Overall, malaria prevalence was 57.8% (95% CI: 0.32-0.74) n=90, with baseline prevalence rate of 58.5% (95% CI: 0.67-1.13), n=65 and 2nd follow-up survey prevalence of 42.0% (95% CI: 0.52-0.76) n=66. At all the two parasitological follow-up survey points, house screening significantly reduced the malaria prevalence by 43% (p< 0.001). Housing improvement has potential to reduce indoor vector densities and malaria prevalence.

SPATIO-TEMPORAL DISTRIBUTION OF AEDES SPECIES (DIPTERA: CULICIDAE) IN FOUR LOCAL GOVERNMENT AREAS IN LAGOS STATE, NIGERIA

Hala S. Thabet[1], Reham A. TagEldin[1], Samuel O. Babalola[2], Oyeniyi Tolulope[2], Olanrewaju Adekunle[2], Oluwakemi Adetunji[2], Romoke Izekor[2], Olagundoye Olalekan[2], Ahmed Omotayo[2], Olakiigbe Abiodun[2], Taye Adekeye[2], Chidinma Isaac[2], Phillip O. Oyale[3], Adedapo O. Adeogun[2], James F. Harwood[1]

[1]U.S. Naval Medical Research Unit-3 (NAMRU-3), Cairo detachment, Egypt, [2]Public Health and Epidemiology Department, Nigerian Institute of Medical Research, Lagos State, Nigeria, [3]Integrated Vector Management Department, National Malaria Elimination Program, Abuja, Nigeria

The frequency and magnitude of arbovirus outbreaks that are transmitted by Aedes mosquitoes are increasing globally, driven by ecologic, economic, and social factors. Therefore, it is imperative that more detailed monitoring be conducted to enhance the distribution and abundance predictions of the Aedes species to update the risk assessment of arbovirus transmission and improve the planning capabilities of public health decision-makers. Here we aimed at developing a Geographic Information System-based overlay on the spatio-temporal distribution of Aedes species collected from four local government areas (LGAs) in Lagos State (urban; Yaba and Somolu, and rural; Ikorodu and Badagry). Adult trapping was conducted for three consecutive nights on a monthly basis from October 2021 through August 2022, using BioGents lure baited traps. A total of 2,204 mosquitoes were collected and identified revealing 2,148 Aedes mosquitoes belonging to two species: Aedes albopictus (94.7% of specimens) and Aedes aegypti (5.3% of specimens). Results indicated dominant occurrence of Aedes albopictus in the four LGAs in comparison to Aedes aegypti. The highest number of Aedes albopictus was collected from Somolu (accounting for 80.5% of collection records), followed by Badagry (8.1%), Ikorodu (6.2%) and Yaba (5.2%). Of the 114 collected Aedes aegypti, 72% were collected from Somolu compared to other LGAs (22.8% Ikorodu, 5.2% Yaba and 0% Badagry). Both Aedes species were most prevalent during the rainy seasons (accounting for 67% of total) compared to the dry seasons.

Understanding the behavior and ecology of local malaria vectors is essential for the effectiveness of the commonly used vector-targeted malaria control tools in areas of low malaria transmission. This study was conducted to

determine species composition, biting behavior and infectivity of the major Anopheles vectors of Plasmodium falciparum in low transmission settings in central Senegal. Adult mosquitoes were collected using human landing catches during 2 consecutive nights and Pyrethrum Spray Catches in 30–40 randomly selected rooms, from July 2017 to December 2018 in 3 villages. Anopheline mosquitoes were morphologically identified using conventional keys; their reproductive status assessed by ovary dissections, and a sub-sample of An. gambiae s.l. were identified to species level using polymerase chain reaction (PCR). Plasmodium sporozoite infections were detected using real-time quantitative PCR. During this study 3684 An. were collected of which 97% were An. gambiae s.l., 0.6% were Anopheles funestus, and 2.4% were An. pharoensis. Molecular identification of 1,877 An. gambiae s.l. revealed a predominance of An. arabiensis (68.7%), followed by An. melas (28.8%), and An. coluzzii (2.1%). The overall human-biting rate of An. gambiae s.l. was highest in the inland site of Keur Martin with 4.92 bites per person per night, while it was similar in the deltaic site, Diofior (0.51) and the coastal site, Mbine Coly (0.67). Parity rates were similar in An. arabiensis (45%) and An. melas (42%). Sporozoite infections were detected in both An. arabiensis and An. melas with the respective infection rates of 1.39% (N = 8) and 0.41% (N = 1). Results suggest that low residual malaria in central Senegal is transmitted by An. arabiensis and An. melas. Consequently, both vectors will need to be targeted as part of malaria elimination efforts in this area of Senegal.

TOWARDS ENVIRONMENTAL SURVEILLANCE OF THE INVASIVE VECTOR SPECIES ANOPHELES STEPHENSI IN SUB-SAHARAN AFRICA

Mojca Kristan[1], Holly Acford-Palmer[1], Monica Oliveira Campos[1], Emma L. Collins[1], Jody Phelan[1], Natalie M. Portwood[1], Bethanie Pelloquin[1], Sian Clarke[1], Jo Lines[1], Taane G. Clark[1], Thomas Walker[2], Susana Campino[1], **Louisa Alexandra Messenger**[3]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]University of Warwick, Warwick, United Kingdom, [3]University of Nevada, Las Vegas, Las Vegas, NH, United States

Anopheles stephensi is a highly competent malaria vector whose historical distribution encompassed the Indian subcontinent, parts of South-East Asia and the Arabian Peninsula. Recently it has become an invasive vector species in the Horn of Africa, where it was first reported in Djibouti in 2012 and since then has spread to Ethiopia, the Republic of Sudan, Somalia, Yemen and most recently Nigeria and Kenya. Unlike An. arabiensis, the main regional malaria vector species, An. stephensi breeds in man-made water containers, buckets, discarded tyres, and water storage tanks for domestic use and construction. These are sites that may not be under routine surveillance by the National Malaria Control Program; such larval habitats are often used by arbovirus-transmitting Aedes species. To inform prospective control strategies, novel surveillance methods for tracking An. stephensi dispersal dynamics and insecticide resistance mechanisms are urgently required, which are both agnostic to mosquito larval morphology and simple to implement at the sampling stage. Using new multiplex TaqMan assays, specifically targeting An. stephensi and Ae. aegypti, we validated the use of environmental DNA (eDNA) for simultaneous vector detection in shared artificial breeding sites. Study findings demonstrated that An. stephensi and Ae. aegypti eDNA deposited by as few as one second instar larva in 1L of water was detectable. Characterization of molecular insecticide resistance mechanisms, using amplicon-sequencing panels (targeting genetic fragments of the voltage-gated sodium channel, acetylcholinesterase and glutathione-s-transferase epsilon 2) for both vector species, was possible from eDNA shed by as few as 16-32 s instar larvae in 50ml of water. An. stephensi eDNA, derived from emergent pupae for 24h, was remarkably stable, and still detectable 2 weeks later. eDNA surveillance has the potential to be implemented in local endemic communities and at points of country entry, to monitor the spread of invasive vector species. Ongoing community studies are validating the feasibility of this technique under field conditions.

5195

DIFFERENTIAL RISK OF EXPOSURE TO ANOPHELES GAMBIAE S.L. AND AN. FUNESTUS S.L. BITING ESTIMATED FROM HUMAN BEHAVIOR OBSERVATION ADJUSTED ANALYSIS IN MALAWI

Leonard Dandalo[1], Yemane Yihdego[2], Fred Sande[3], Charlotte Banda[3], Ganizani Kapito[3], Medson Kamwana[3], Lusungu Chamdimba[3], Luckson Sichone[3], Martin Chiumia[3], Abdoulaye Bangoura[1], Jules Nahimana[1], Miriam Williams[2], Pius Masache[4], Lilia Gerberg[5], Jenny Donnelly[5], Themba Mzilahowa[3]

[1]U.S. President's Malaria Initiative VectorLink Project, Abt Associates,, Lilongwe, Malawi, [2]U.S. President's Malaria Initiative VectorLink Project, Abt Associates, Rockville, MD, United States, [3]Malaria Alert Centre, Kamuzu University of Health Sciences, Blantyre, Malawi, [4]U.S. President's Malaria Initiative, USAID, Lilongwe, Malawi, [5]U.S. President's Malaria Initiative, USAID, Washington, DC, United States

Human behavior plays a vital role in determining the effectiveness of malaria vector control interventions. Human behavior observations (HBO) help in the identification of human-vector exposure points and periods, thereby determining gaps in protection. This information can be used to target malaria vectors with supplementary control interventions. In Malawi, Anopheles funestus s.l. and An. gambiae s.l. are the main malaria vectors and indoor residual spraying and insecticide treated nets (ITNs) are the main vector control interventions. To assess the intersection between mosquito bites and human behavior, we collected HBO data, alongside human landing catches (5pm to 11am) from July 2021 to June 2022 in six high malaria risk districts of Nkhata Bay, Nkhotakota, Mangochi, Balaka, Kasungu and Salima. During each quarterly visit, a supervisor recorded the time household members went inside their houses, went to sleep, woke up, exited the house and net usage. Weighted estimates of mosquito biting rates according to human behavior were generated. Overall, by 10 pm, 95.0% of people were inside their houses and 60.0% sleeping under net. Eighty-six percent of An. funestus s.l. and 62.0% of An. gambiae s.l. bites occurred when people were indoors and asleep. The HBO adjusted proportion of bites prevented by sleeping under net was higher for An. funestus s.l. (56.2%) than An. gambiae s.l. (40.5%). The proportion of bites occurring outdoors for unprotected individuals was higher for An. gambiae s.l. (35.1%) than An. funestus s.l. (10.7%). The proportion of outdoor bites early in the night (5-11pm) was higher for An. gambiae s.l. (69.8%) than An. funestus s.l. (54.3%). The proportion of indoor biting occurring between 11pm and 6am was similar for both An. gambiae s.l. and An. funestus s.l. (87.0%). However, overall indoor bites from An. funestus s.l. were more than three times higher that of An. gambiae s.l. (25.2 vs 7.3 bites/person/ night). ITNs are appropriate intervention since most of the human-vector contact occur indoors while people are asleep. An increase in ITN usage above the current 60% would substantially reduce transmission in these districts.

5196

ENTOMOLOGICAL AND MOLECULAR SURVEILLANCE OF MALARIA VECTORS IN A RURAL COMMUNITY IN BENGUELA, ANGOLA: IMPLICATIONS FOR LONG-LASTING INSECTICIDE TREATED NET (LLIN) DISTRIBUTION AND VECTOR CONTROL STRATEGIES

Arlete Dina Troco[1], Gonçalo Alves[1], Gonçalo Seixas[2], Cani Pedro Jorge[3], José Franco Martins[3], Alfredo Francisco[4], Carla Sousa[2], Teresa Nobrega[1], Sérgio Lopes[1]

[1]The Mentor Initiative, Luanda, Angola, [2]Global Health and Tropical Medicine, Instituto de Higiene e Medicina Tropical, Universidade Nova de Lisboa, Lisboa, Portugal, [3]National Malaria Control Programme, Ministry of Health, Luanda, Angola, [4]World Vision, Luanda, Angola

The use of Long-Lasting Insecticide Treated Net (LLIN) remains the primary method for malaria vector control in Angola. In preparation for a mass distribution of LLINs, a malaria entomological survey was conducted in the Benguela province to determine the abundance and behaviors of key malaria vectors in the area. The study focused on Alto Catumbela, a rural community with a history of malaria transmission. Female mosquitoes

were sampled using indoor CDC light traps from February to July 2022. Morphological and molecular identification techniques were used to identify the species and Plasmodium falciparum (Pf) infection status of collected Anopheles mosquitoes. The presence of knockdown resistance mutations (kdr) in An. gambiae complex was also investigated.Of the 715 female An. sp. mosquitoes collected indoors, 60.3% were identified as An. funestus sl, 11.7% as An. gambiae sl, and 28% as other Anopheles species. Molecular identification revealed that An. gambiae sl comprised of 59.5% An. gambiae ss and 31% An. arabiensis. An. funestus group consisted of 83.3% An. funestus ss and 0.5% An. vaneedeni. The overall Pf infection rate was 5.3% in An. funestus ss and 2.3% in An. gambiae ss. The Human Blood Index for An. funestus ss and An. gambiae ss was 100%. Notably, the 1014S (kdr-east), an allele associated with pyrethroid insecticide resistance, was identified for the first time in An. gambiae ss but only in heterozygotes. An. gambiae ss also exhibited a high frequency of the 1014F (kdr-west) kdr mutation. An. arabiensis were found to be wild type.The study highlights An. funestus as the primary malaria vector in the Alto Catumbela during the collection period. The low number of An. gambiae sl captured indoors may indicate a possible behavioral adaptation to previous indoor vector control methods. The presence of kdr mutations in An. gambiae ss is concerning and warrants attention regarding potential pyrethroid insecticide resistance. Overall, this study provides valuable information on the abundance, species composition, and infection status of malaria vectors in the Benguela province, which can inform effective malaria control strategies in the region.

5197

COMPOSITION AND SEASONALITY OF ANOPHELES GAMBIAE S.L. AND AN. FUNESTUS S.L. IN LIBERIA

Ibrahima Baber[1], Yemane Yihdego[2], Chrispin Williams[3], Odell Kumeh[3], Tuwuyor Belleh[4], Georges Gweh[3], Agnes Nador[3], Uwem Inyang[5], Melissa Yoshimizu[6]

[1]U.S. President's Malaria Initiative VectorLink Project, Abt Associates Inc., Monrovia, Liberia, [2]President's Malaria Initiative, VectorLink Project, Abt Associates Inc., Rockville, MD, United States, [3]National Malaria Control Program, Ministry of Health, Monrovia, Liberia, [4]President's Malaria Initiative VectorLink Project, Abt Associates Inc., Monrovia, Liberia, [5]U.S. President's Malaria Initiative, US Agency for International Development, Monrovia, Liberia, [6]U.S. President's Malaria Initiative, US Agency for International Development, Washington DC, MD, United States

Vector monitoring is critical in understanding the potential dynamics of malaria transmission and making informed decisions in the selection of control interventions and evaluating their impact. To better understand malaria vector composition and seasonality in Liberia, we collected mosquitoes monthly from eight sites in seven counties from September 2021 to October 2022. Three adult mosquito collection methods were used: pyrethrum spray catch (PSC), human landing catch (HLC) and CDC light traps (CDC-LTs). A total of 7748 Anopheles gambiae s.l. (76%), 2417 An. funestus s.l. (24%) and 21 other Anopheles species (0.2%) were collected. More than 98% of mosquitoes collected were An. gambiae s.l. at Jackson Farm, Madina, Saint John and Gbedin Camp3. The population started to increase in March and reached peak from May to July, coinciding with the beginning of the rainy season. After July, the vector population start to decrease gradually. Anopheles funestus s.l. was dominant in Zeansue (89%), where the population started to increase in January and peaked in March-May, which is during the dry season. During the collection period, the average number of An. gambiae s.l collected by method were: 0.87/house/day by PSC, 1.6/trap/night by CDC-LT and 5.8 bites/person/night by HLC; with a similar pattern observed for An. funestus s.l. Of the three collection methods, HLC was the most efficient in mosquito trapping. Twenty one percent (2138/10165) of the combined An. gambiae s.l. and An. funestus s.l. were collected from Zeansue, 19% (1882/10165) were from Saint John and the lowest was from Fissebu, 2% (250/10165). Malaria vector density and composition varied by site with a combined high peak over five months per year. Sites with higher density of malaria vectors, An. gambiae s.l. and An. funestus s.l., could indicate a higher risk of exposure for malaria transmission. Further molecular analysis for of An. gambiae complex and the An. funestus group will help to identify the species composition, parasite infection rate and host blood meal analysis to better understand trends in malaria transmission risk by space and time.

5198

THE IMPACT OF FOUR YEARS OF INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS METHYL AND CLOTHIANIDIN ON ENTOMOLOGICAL DRIVERS OF MALARIA TRANSMISSION IN BURKINA FASO, WEST AFRICA

Dieudonné Diloma Soma[1], Aristide S. Hien[2], Adama Koné[3], Birame Mame Diouf[4], Sheila Barasa Ogoma[5], Allison Belemvire[6], Djenam Jacob[5], Samson Taiwo Awolola[7], Roch Kounbobr Dabiré[2]

[1]Institut de Recherche en Sciences de la Santé / UNB, Bobo-Dioulasso, Burkina Faso, [2]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [3]PMI VectorLink Project, Abt Associates, Ouagadougou, Burkina Faso, [4]US President's Malaria Initiative, US Agency for International Development, Ouagadougou, Burkina Faso, [5]PMI VectorLink Project, Abt Associates Inc, Rockville, MD, United States, [6]US President's Malaria Initiative, US Agency for International Development, Washington, DC, United States, [7]US President's Malaria Initiative, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Since 2018, indoor residual spraying (IRS) has been performed by the National Malaria Control Program in the high-burden districts of Kampti and Solenzo using SumiShield® 50 WG (clothianidin: neonicotinoid), Actellic® 300CS (pirimiphos-methyl: organophosphate) and Fludora Fusion® WP-SB (clothianidin + deltamethrin: pyrethroid) in Burkina Faso. Routine entomological surveillance was conducted to measure the impact of IRS on entomological drivers of malaria transmission. Anopheles gambiae s.l. were sampled monthly from June to December by human landing and pyrethrum spray catches in two sprayed and two unsprayed sentinel sites to measure entomological inoculation rates (EIRs). The residual activity of insecticides was also assessed using the WHO cone test. After the first round of IRS in 2018, there was a significant decrease in malaria transmission in all sprayed districts compared with unsprayed districts as shown by reduced EIR (RR=19.75, CI95%= [8.71-33.45], P<0.001). From 2019 to 2021, the EIR was significantly lower in Kampti compared to Gaoua (unsprayed district) (RR=13.12, CI95%= [4.35.71-21.18] P<0.001). In Solenzo, the EIR varied from one year to the next, but the reduction was not significant. SumiShield® 50 WG and Fludora Fusion® WP-SB lasted more than 7 months covering the malaria transmission period, compared to Actellic® 300CS, which lasted 5 months. These findings highlight varying entomological impact of the IRS at the two sites, in an effort to reduce malaria transmission.

5199

CIRCUMSPOROZOITE POSITIVE ANOPHELES LONGIPALPIS C MOSQUITO IDENTIFIED IN ZIMBABWE

Charmaine C. Matimba[1], Nobert Mudare[1], Tanatswa X. Gara[1], Brenda Makonyere[1], Trust Nyakunu[1], Aramu Makuwaza[1], David Nyasvisvo[2], Hieronymo Masendu[2], Sungano Mharakurwa[1], Cristina Rafferty[3], Adeline Chan[4]

[1]Africa University, Mutare, Zimbabwe, [2]PMI Vectorlink, Harare, Zimbabwe, [3]Entomology Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]U.S. President's Malaria Initiative, Entomology Branch, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Surveillance of malaria vectors in Zimbabwe has historically focused on the two major vectors Anopheles gambiae s.l and An. funestus s.l., both morphologically indistinguishable species groups that require molecular tools for species identification. During routine malaria vector surveillance in rainy and fertile Burma Valley, 174 samples that were identified morphologically as An. funestus s.l., but failed to amplify when processed using the standardized An. funestus s.l. species ID multiplex PCR assay, were sequenced for follow-up and 35 were identified as Anopheles longipalpis C. The finding prompted the Africa University laboratory to investigate the distribution and behavior of An. longipalpis C in Zimbabwe.

Of 1841 An. funestus samples, 529 that had previously amplified the double band pattern matching An. longipalpis C in the An. funestus PCR assay were revisited and analyzed for distribution, biting behaviour, and sporozoite parasite detection. The findings indicate that An. longipalpis C was first collected in 2016 in Burma Valley and through 2022 in Beitbridge, Chakohwa, Burma Valley, Zindi, Acturus, Vumba, Mubairakuenda, Kawere, Makarara, Dendera, and Chiyadzwa. Of 180 blood fed samples, 74.4% were cattle-fed, 11.6% exhibited multiple host meals with a combination of human and animal blood, and 13.8% fed on other animals. Circumsporozoite ELISA testing found one Makarara sample from 2021 to be positive for Plasmodium falciparum (0.5% infectivity). Data in this study revealed An. longipalpis C to be widely distributed in Zimbabwe and supports that An. longipalpis C is still predominantly zoophagic, preferring cattle blood. However, the number of samples positive for combined animal and human blood and the single positive sample suggest An. longipalpis C, its distribution, and behaviour should be closely monitored by national malaria programs. This study highlights the importance of investigating PCR species identification results that don't amplify, to characterize Anopheles species composition and detect previously unidentified Anopheles species and their potential contributions to the spread of malaria.

5200

RESURGENCE OF MALARIA IN UGANDA COINCIDES WITH AN INCREASE IN ABUNDANCE OF ANOPHELES FUNESTUS WITH EVIDENCE OF VARIATION IN SUSCEPTIBILITY TO CLOTHIANIDIN

Ambrose Oruni[1], Jackson Asiimwe[1], Daniel Ayo[1], Kyle J. Walker[2], Hanafy M. Ismail[2], Mark J I Paine[2], Henry D. Mawejje[1], Melissa D. Conrad[3], Paul Krezanoski[3], Emmanuel Arinaitwe[1], Jonathan Kayondo[4], Charles S. Wondji[5], Sarah G. Staedke[2], Teun Bousema[6], Moses R. Kamya[1], Grant Dorsey[3], Martin J. Donnelly[2]

[1]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda, [2]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of California San Francisco, San Francisco, CA, United States, [4]Department of Entomology, Uganda Virus Research Institute, Entebbe, Uganda, [5]Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon, [6]Department of Medical Microbiology, Radboud University, Nijmegen, Netherlands

Historically, Anopheles gambiae mosquitoes are responsible for the majority of malaria transmissions in Uganda where vector control is reliant upon indoor residual spraying (IRS) or long-lasting insecticidal nets (LLINs). After 5 years of using Bendiocarb followed by Actellic® for IRS, in 2020 Uganda switched to clothianidin-based formulations (Fludora® and Sumishiled®). Following this switch, there has been an apparent resurgence in malaria cases, prompting an investigation. From 2022-23, a 12-month longitudinal survey was conducted in Tororo, one of the IRS districts, utilizing 60 households enrolled in a prospective cohort study. Vector abundance was estimated using CDC-light traps, and assessment of the effectiveness of the IRS used wall cone bioassays and HPLC analysis of samples from sprayed surfaces. Resistance phenotyping was also performed using CDC bottle assays. The data showed a significant change in the abundance and composition of malaria vectors with An. funestus proportion increasing from 10.4% (8.9 - 12.1; 95% CI) of total collections before IRS with clothianidin to 65.2% (61.8 - 68.5; 95% CI) afterwards. Wall cone assays showed that the average mortality in An. gambiae mosquitoes was high (90% - 98%) up to 12 months post spraying. When tests were performed in the same houses, An. funestus had a significantly lower knockdown (7.3%) (F=12.49, df=20, P=0.00083) and 48h mortality (76.1%) (F=3.34, df=20, P=0.0048) compared to An. gambiae (knockdown = 50.9%, 48h mortality = 98.2%). In CDC bottle assays, mortality of wild-caught An. gambiae was 100% at 48h post exposure. HPLC analysis revealed that there was a marked variation in the amount of insecticide on walls ranging from <5 mg/m2 to >200 mg/m2. All houses in all rounds of sampling had less than the recommended dosage of 0.5g/m2 . Overall, these investigations suggest that the malaria resurgence may be driven by An. funestus that is more tolerant to clothianidin-based formulations than An. gambiae. Further investigations including full resistance characterization and examination of behavioural response to clothianidin treated surfaces is currently ongoing.

5201

IMPACT OF ENVIRONMENTAL MODIFICATION ON THE DYNAMICS, BEHAVIOR, TRANSMISSION RISK AND INSECTICIDE RESISTANCE OF MALARIA VECTORS: THE CASE OF ARJO-DIDESSA SUGARCANE IRRIGATION SCHEME, SOUTHWESTERN ETHIOPIA

Assalif Demissew[1], Abebe Animut[2], Solomon Kibret[3], Dawit Hawaria[4], Arega Tsegaye[5], Teshome Degefa[5], Hallelujah Getachew[6], Ming-Chieh Lee[3], Guiyun Yan[3], Delenasaw Yewhalaw[5]

[1]Ambo University, Ambo, Ethiopia, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]University of California, Irvine, California, CA, United States, [4]Hawassa University, Hawassa, Ethiopia, [5]Jimma University, Jimma, Ethiopia, [6]Arba Minch College of Health Sciences, Arba Minch, Ethiopia

Ethiopia is expanding extensive irrigation developments to meet food demands and alleviate poverty in the country. However, the effect of such water development projects on malaria transmission risk is not well investigated. Moreover, agrochemicals used in irrigation activities are blamed to drive resistance selection in malaria vectors. Studies evaluating the impact of these agrochemicals on malaria vector's resistance are lacking. This study investigated impact of sugarcane irrigation on vector dynamics, behavior, transmission risk and insecticide resistance of malaria vectors in Southwestern Ethiopia. Adult Anopheles mosquitoes were collected using CDC light traps and human landing catches from irrigated and non-irrigated clusters of Arjo-Didessa sugarcane irrigation scheme in wet and dry seasons, between 2018 to 2021. Mosquito species composition, abundance, seasonality, behavior (biting & blood feeding) and Plasmodium infection rates were compared. Mosquitoes were identified to species morphologically and using molecular techniques. Mosquito host blood meal sources were determined by polymerase chain reaction (PCR). Plasmodium sporozoite infections were analyzed using CSP ELISA. Adult Anopheles gambiae s.l. were tested for their susceptibility to insecticides using WHO tube test. Among 6,058 female Anopheles mosquitoes collected, 72.3% (n= 4379) were from irrigated and 27.7% (n= 1679) from non-irrigated clusters. Mosquito composition, abundance and density was significantly higher in the irrigated than non-irrigated clusters during the wet and dry seasons. Anophelines in the irrigated clusters were more anthropophagic and showed overnight as well as outdoor biting activity. A 2-fold higher Plasmodium infection rates were recorded in the irrigated than non-irrigated areas. Anopheles gambiae s.l. was resistant to deltamethrin and alphacypermethrin insecticides. Thus, malaria vector interventions should be strengthened in Arjo-Didessa sugarcane irrigation scheme to reduce malaria transmission risk during wet and dry seasons. Integrated resistance management strategies should also be implemented.

5202

DISTRIBUTION OF ANOPHELES MOSQUITOES AND THEIR ROLE IN MALARIA TRANSMISSION IN SOUTHWESTERN ETHIOPIA

Nigatu Eligo[1], Teklu Wegayehu[1], Myrthe Pareyn[2], Girum Tamiru[1], Bernt Lindtjørn[3], Fekadu Massebo[1]

[1]Arba Minch University, Arba Minch, Ethiopia, [2]Institute of Tropical Medicine, Antwerp, Belgium, [3]University of Bergen, Bergen, Norway

The species distribution of malaria mosquitoes and their role in disease transmission varies from place to place. Hence, updating the species distribution and identifying their role is essential to design appropriate interventions. This study aimed to assess the Anopheles mosquito species and their infection rate in Southwest Ethiopia. A cross-sectional multistage sampling technique of adult malaria mosquitoes was done from June 2018 to July 2019. With a purposeful selection process, four malaria-endemic zones in the region, two malaria-endemic districts in each zone, and two malarious villages in each district were chosen. Ten per cent of households in each village were visited once to collect adult mosquitoes using Center

for Disease Control and Prevention (CDC) light traps. The head and thorax of adult Anopheles mosquitoes were evaluated for circum-sporozoite proteins (CSPs). At the same time, legs and wings were used to identify sibling species using a polymerase chain reaction (PCR). A total of 1445 Anopheles mosquitoes were examined, comprising eight species, An. arabiensis (84.9%), An. parensis (9.1%), An. pharoensis (4.8%), An. pretoriensis (0.6%), An. demeilloni (0.2%), An. kingi (0.1%), An. sergentii (0.1%), and An. tenebrosus (0.1%). Of 813 An. gambiae complex evaluated by PCR, 97% (785/813) were An. arabiensis and 3% (28/1445) were not amplified. There were 133 An. funestus complex tested for speciation, 88% (117/133) were positive for An. parensis, and 11% (15/133), were not amplified. A single specimen (1%) amplified for An. funestus complex primers was not among the complex species and was later confirmed as An. sergentii by DNA sequencing. Among the 1399 Anopheles tested for CSPs by ELISA, Plasmodium falciparum CSP rate was 0.4% (95% CI: 0.1-0.8), and it was 0.1% (95% CI: 0.002-0.4) for P. vivax. An. arabiensis and An. pharoensis were widely distributed species in the region, but only An. arabiensis was found to be positive for CSPs. Anopheles arabiensis is the primary vector of malaria in the region.

5203

UPDATED ASSESSMENT OF ANOPHELES STEPHENSI PRESENCE IN SOUTHERN YEMEN

Alia Zayed[1], Yasser Baheshm[2], James F. Harwood[3]

[1]Naval Medical Research Unit No. 3, Cairo, Egypt, [2]National Malaria Control Program, Aden, Yemen, [3]Naval Medical Research Unit No. 3, Sigonella, Italy

The invasive malaria vector Anopheles stephensi has currently been the focus of attention in the horn of Africa and adjacent countries, since its 2013 introduction to East Africa. Although malaria is endemic in Yemen, the introduction of this vector to the country may drive urban malaria transmission, adding to the current malaria burden, traditionally transmitted by the native vector An. arabiensis in rural areas. Vector surveillance was conducted in nine Governorates covering all southern areas, including Socotra Island, with sites specifically selected from Aden, Lahij and Hadramout based on malaria cases and human populations' records. Larval collection and spray catch methods were conducted to collect mosquitoes An. stephensi larvae were found either alone or coexisting with other species in artificial and natural containers in urban settings. Geospatial and prediction maps were generated to show vector distribution. Species composition, diversity, spatio-temporal distribution, and population dynamic of both An. stephensi and An. arabiensis were observed. The current invasive vector's population dynamic, establishment, the associated sociocultural factors, and the optimization of control measures will be discussed.

5204

CHANGES IN THE BITING BEHAVIOR OF ANOPHELES GAMBIAE S.L. FOLLOWING THE COMBINATION OF MASS-DISTRIBUTION CAMPAIGNS OF INSECTICIDE-TREATED NETS AND INDOOR RESIDUAL SPRAYING OVER FIVE YEARS IN KIREMBA, NORTHERN BURUNDI

Denis Sinzinkayo[1], Pierre Sinarinzi[2], Landrine Mugisha[2], Théogène Ndayishimiye[2], Darius Habarugira[3], Louise Mahan[3], Jenny Carlson[4], Aklilu Seyoum[5]

[1]Abt Associates, Bujumbura, Burundi, [2]National Malaria Control Programme, Bujumbura, Burundi, [3]USAID, Bujumbura, Burundi, [4]USAID, USA, WA, United States, [5]Abt Associates, Rockville, MD, United States

In Burundi, malaria remains a major public health problem, and was responsible for 46% of outpatient consultations and 59 % of hospital deaths in 2021. Anopheles gambiae s.l. is the major malaria vector, and insecticide treated nets (ITNs) and indoor residual spraying (IRS) are the core vector control interventions in the country. Unlike the other entomological monitoring sites in the country, Kiremba health district in northern Burundi received both ITNs, distributed during the 2017 and 2019 mass- campaigns, and yearly IRS implemented from 2017 to 2021. Pyrethroid-treated nets were distributed in 2017 and 2019 whereas, for IRS a carbamate insecticide (bendiocarb) was sprayed in 2017 and 2019 followed by Fludora Fusion (a mixture of neonicotinoid and pyrethroid insecticides) up to 2021. As part of the regular monitoring on the impact of interventions, monthly entomological surveys were conducted using human landing catches to assess malaria vectors feeding behavior. Mosquitoes were collected both indoors and outdoors with four collectors for two consecutive nights in four selected houses. The indoor and outdoor human biting rates (HBRs) of the An. gambiae s.l. compared using the Kruskal-Wallis test. The mean HBR (bites/person/night) of An. gambiae s.l. was similar indoors and outdoors in 2017 (p= 0.27); in 2018 (p=0.46), and in 2019 (p=0.16). Contrary to the previous years, the biting activity was higher outdoors than indoor in 2020 (p= 0.04) and 2021 (p= 0.001). The results indicated the shift in biting behaviors of An. gambiae s.l., from equally feeding indoor and outdoor to predominantly outdoor feeding in Kiremba might be associated with continuous indoor based vector control interventions in the area.

5205

SURVEILLANCE OF AEDES-BORNE ARBOVIRUSES IN SELECTED SITES IN THE SAVANNA REGION OF GHANA

Mavis Koryo Ofei[1], Mufeez Abudu[1], Helena A. Boakye[1], Jane Ansah-Owusu[1], Aaron A. Lartey[1], Paul K. Botwe[2], Joseph H.N Osei[1], Seth O. Addo[1], Joseph K. Bonney[1], Jewelna Akorli[1], Samuel K. Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]School of Public Health, University of Ghana, Accra, Ghana

Aedes-borne arboviruses such as yellow fever (YFV), dengue (DENV), chikungunya (CHIKV), and zika (ZIKV) have increasingly become a critical public health concern worldwide. Many countries all over the world including Africa have experienced emergence and re-emergence of these arboviruses in the past and in recent times. In October 2021, Ghana experienced yellow fever outbreak in the Savanna region. Recent studies showed antibodies to Dengue virus serotype-2 among febrile illness patients in some areas of the Greater Accra region although the virus has not been detected in vectors. Therefore, this study assessed the prevalence of Aedes mosquitoes in Sawla, Larabanga and the Mole National Park, as well as the arboviruses (YFV, DENV, CHIKV, and ZIKV) they may be harboring, as a follow up to the yellow fever outbreaks in these areas. A cross-sectional study was conducted in three study sites (Sawla, Larabanga and Mole National Park). Adult Aedes mosquitoes were collected using the Biogent sentinel traps and immature stages (eggs, larvae, and pupae) were sampled using ovitraps and dippers. The immature stages were raised to adults for identification using morphological keys/features and viral analyses using RT-PCR. Data analysis was performed using two-way ANOVA in excel. A significantly higher number of eggs were collected in Sawla as compared to Larabanga and the Mole National Park ($P < 0.05$). The positive ovitrap index (POI) was high (>10) in all three sites; Sawla: POI = 50%; Larabanga: POI = 50%; Mole National Park: POI = 60%. All the Aedes mosquitoes identified from the three sites were Ae. aegypti, specifically of the subspecies Ae. aegypti formosus. No arbovirus (YFV, DENV, CHIKV, and ZIKV) was detected from the mosquitoes collected after analysis by RT-PCR. The study found that there is a high-risk of Aedes-borne arboviruses in the study areas and regular surveillance is needed to prevent and contain outbreaks.

5206

PILOTING THE USE OF TRANSFLUTHRIN-TREATED EAVE RIBBONS AS A SUPPORTING VECTOR CONTROL TOOL IN A HIGH TRANSMISSION SETTING IN ZAMBIA

Mary E. Gebhardt[1], Mbanga Muleba[2], Douglas E. Norris[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Diseases Research Centre, Ndola, Zambia

Nchelenge District, Zambia still experiences holoendemic malaria transmission despite over ten years of annual indoor residual spray (IRS)

and intermittent insecticide treated net (ITN) distribution. High levels of resistance to pyrethroids have been demonstrated among the most prominent vector, Anopheles funestus, which may contribute to the lack of effect of these indoor interventions. We examined the insecticidal activity, protective effect, longevity, and acceptance of transfluthrin-treated eave ribbons in Nchelenge District, Zambia. Two household clusters were identified, and transfluthrin-treated eave ribbons were distributed to every household in cluster 1, while cluster 2 received no additional intervention beyond their existing ITNs and annual IRS. Anophelines were collected monthly from 40 households using indoor and outdoor CDC light traps and Prokopak aspirations indoors. Anophelines were morphologically identified and tested for the presence of Plasmodium falciparum sporozoites. Household-level surveys identified key human behaviors that may play a role in the success or failure of the intervention, including evening outdoor activities, outdoor sleeping, and overall acceptance of the spatial repellant. We hypothesize that these ribbons will reduce overall indoor and peri-domestic abundance in treated households, leading to reduced contact with humans and reduced pathogen transmission.

5207

TREATED EAVE SCREENS IN COMBINATION WITH SCREENED DOORS AND WINDOWS, ARE MORE EFFECTIVE THAN UNTREATED EAVE SCREENS IN A SIMILAR COMBINATION IN REDUCING INDOOR AND OUTDOOR ANOPHELES POPULATIONS UNDER SEMI-FILED CONDITIONS IN WESTERN KENYA

Bernard Onyango Abong'o[1], Silas O. Agumba[1], Vincent O. Moshi[1], Jacob Simwero[2], Jane Otima[2], Eric O. Ochomo[1]

[1]KEMRI - KENYA, Kisumu, Kenya, [2]Habitat For Humanity International, Nairobi, Kenya

Human dwellings remain the main point of human-mosquito interaction leading to malaria transmission despite sustained use of insecticide-treated nets (ITNs) and indoor residual spraying (IRS). Simple structural modifications have great potential to prevent mosquito entry into houses and reduce malaria transmission. The study utilized four huts, each constructed inside a separate semi-field structure (SFS) for the experimental release of mosquitoes. Two huts had screened eaves, doors, and air cavities in place of windows while the other two were unscreened. In experiment 1, the eave screened was untreated while in Experiment 2, the eave screen was treated with Actellic® insecticide. The modification cost was less than 250usd/structure. First filial (F1) generation of Anopheles funestus from Siaya, F0 reared from An. arabiensis larvae collected from Ahero and An. arabiensis Dongola strain from the insectary were raised to 3-day-old adults and used in experiments. Two hundred, 3-day old adults of each species were released in each semi-field structure at dusk and recaptured the following morning, counted and recorded by the collection location of each hut. A single volunteer slept in each hut under an untreated bed net each night. Significantly fewer An. arabiensis from Ahero RR=0.10; (95%CI: 0.02-0.63), An. arabiensis Dongola strain RR=0.11; (95%CI: 0.06 - 0.19) and An. funestus from Siaya RR=0.10; (95%CI: 0.06-0.17) were observed inside modified huts compared to unmodified ones. Treating of eave screen material significantly reduced the numbers An. arabiensis from Ahero RR=0.05; (95%CI: 0.00-0.77) and An. arabiensis Dongola strain RR=0.34; (95%CI: 0.18-0.64) indoors of huts with treated eave screen compared to huts with untreated eave screens, while eliminating the An. funestus indoors. Modification of eaves, doors and windows are cheap and effective ways of reducing mosquito entry into houses. Treatment of eave screen material with an effective insecticide further reduced the Anopheles population in and around the screened huts under semi-field conditions and could greatly complement existing vector control efforts.

5208

IMPACT OF LIVESTOCK MANAGEMENT ON MALARIA TRANSMISSION RISKS IN RURAL TANZANIA

Yohana A. Mwalugelo[1], Godfrey C. Katusi[1], Alfred O. Ochieng[2], Fred A. Amimo[2], Emmanuel W. Kaindoa[1]

[1]Ifakara Health Institute, Ifakara, Tanzania, United Republic of, [2]Jaramogi Oginga Odinga University of Science and Technology, Bondo, Kenya

Livestock keeping is one of potential factors associated with malaria transmission. To date, the impact of livestock keeping on malaria transmission is contradicting with some studies reporting a zooprophylaxis effect while others reporting zoopotentiation effect. This study aimed to assess the impact of livestock management on malaria transmission risks in a malaria endemic region in south-eastern Tanzania. A longitudinal study was done in Minepa village. Forty randomly selected houses were sampled, 20 had livestock and others had no livestock. Daily mosquito collection was done in 8 houses each day, to ensure each house was visited once per week from January to March 2023. Indoor collections used CDC-Light traps and prokopack aspirators. Outdoor collections used human-baited double net traps and resting buckets. Poisson GLMM was used to assess the influence of livestock on mosquito density. A total of 18,620 female Anopheles mosquitoes were collected. Out of these, 98% were An. gambiae s.l. while others were An. funestus, An. pharoensis, An. coustani and An. squamosus. The presence of at least one cow (RR = 2.682, 95% CI: 1.492 - 4.320, p = 0.001), dog (RR=1.895, 95% CI: 1.531-2.346, p < 0.001) and chicken (RR=8.387, 95% CI: 4.667-15.073, p < 0.001) near houses was related to increased catches of An. gambiae mosquitoes indoors. The indoor catches of An. gambiae mosquitoes were negatively associated to the presence of at least one sheep (RR=0.345, 95% CI: 0.125-0.953, p=0.04). The outdoor catches, An. gambiae mosquitoes were associated with the presence of at least one goat (RR=7.079, 95% CI: 4.278-11.715, p<0.001) and chicken (RR=0.383, 95%CI:0.185-0.631, p<0.001). The number of An. funestus indoors was higher in houses with chicken (RR=11.627, 95% CI: 2.111-64.032, p=0.005) than those with no chicken. The study shows that the association between livestock keeping and malaria transmission is controversial as there are livestock which increase malaria vectors while others decrease them indoors and outdoors. Thus, zooprophylaxis and other livestock-based malaria interventions should be used with other interventions for malaria control.

5209

WOLBACHIA-INFECTED AEDES AEGYPTI TO CONTROL DENGUE IN DHAKA, BANGLADESH

Hasan Mohammad Al-Amin[1], Leon E. Hugo[1], Gordana Rašić[1], Nigel W. Beebe[2], Gregor J. Devine[3]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]University of Queensland, Brisbane, Australia, [3]QIMR Berghofer, Brisbane, Australia

Arboviral diseases like dengue remain a significant health concern in Bangladesh. The primary approach to controlling dengue is through insecticides, with the vector, Aedes aegypti mosquito, being the main target. However, we confirmed that this strategy is likely to be substantially compromised due to high-intensity insecticide resistance in the Dhaka Ae. aegypti population. Our study revealed high frequencies (~90%) of a homozygous kdr mutation (V1016G) coupled with substantial metabolic resistance. In an experimental free-flight room, domestic and public health aerosols against free-flying and resting Ae. aegypti were mostly ineffective, resulting in up to 74% (±8.21, 95% CI) recovery in 24 hours. Realizing the need for a more sustainable, non-insecticidal approach for dengue control, we then focused on the potential for developing Wolbachia-infected, disease-refractory mosquitoes for release in Dhaka. We created and characterized a wAlbB infected Ae. aegypti with Dhaka genetic background and then compared its fitness to the parental Wolbachia-free Dhaka colony. Complete cytoplasmic incompatibility and maternal transmission were demonstrated, with minimal apparent fitness costs. Similar to the parental Dhaka strain, high-intensity resistance (41 - 54% mortality) to the 10 times diagnostic dose of permethrin was recorded in the wAlbB-Dhaka strain.

Fertility, lifespan, fecundity, and egg viability were comparable with the local Dhaka mosquitoes, and wAlbB-infected males were competitive with local males in mating experiments. Given the lack of substantial fitness cost to host mosquitoes, the insecticide resistance profile of its infected mosquito strain, and the potential for virus blocking, the Wolbachia wAlbB strain is likely to offer a viable alternative to dengue control in Bangladesh.

5210

3D-SCREENS FOR SUSTAINABLE MALARIA CONTROL: OUTCOMES OF PHASE II SEMI-FIELD EVALUATION AND STUDY DESIGN OF A LARGE-SCALE PHASE III EVALUATION IN NORTHEASTERN TANZANIA

Subam Kathet[1], Wema Sudi[2], Victor Mwingira[2], Patrick Tungu[2], Frank Magogo[2], Robert Malima[2], Mikko Aalto[3], Tomi Hakala[4], Marku Honkala[4], William Kisinza[2], Seppo Meri[1], Ayman Khattab[1]

[1]Translational Immunology Research Program Unit and Department of Bacteriology and Immunology, University of Helsinki, Helsinki, Finland, [2]National Institute for Medical Research, Amani Medical Research Centre, Muheza, Tanzania, United Republic of, [3]Bosaso General Hospital, Bosaso, Somalia, [4]Department of Materials Science, Tampere University of Technology, Tampere, Finland

The increasing prevalence of insecticide-resistant malaria vectors has created a need for sustainable vector control alternatives that are non-reliant on insecticides. A novel insecticide-free window screen, called the 3D-Screen, has been developed to exploit mosquitoes' innate attraction to humans. The screen is composed of 3D conical structures with a perforated tip of 5mm and fully open base of 5 cm diameter that are fitted on a traditional screen (100 cones/m2). When installed as a double screen setup in window openings, forming the 3D-Window Double Screen Trap (3D-WDST), its unidirectional function allows mosquitoes to pass from outside only, trapping them between the double screens. In phase I laboratory studies (2015), the 3D-Screens demonstrated a remarkable efficacy, capturing 92% of the host-seeking mosquitoes in a double screen setup. In phase II semi-field studies, we installed 3D-WDST in window openings of experimental huts and found that the 3D-Screens installed on both sides of the window openings (outside and inside) in huts with open eaves were more effective in trapping female Anophelines (FA) than other conditions (efficacy; 33.11%, CI: 7.399 - 58.81). The introduction of baffles in the huts with 3D-WDST resulted in higher trapping efficacy of 70.32% (CI: 56.87 - 83.77) for FA. Comparison of 3D-Screen with machine-made (MM) and handmade (HM) cones showed no significant difference in the weekly mean catch (P=0.1887), however the integral superiority of MM over HM made it the preferred choice for further testing. To elucidate the efficacy of 3D-Screens in community settings, we conducted a large-scale phase III studies in Muheza, Tanzania, enrolling 892 houses from 14 hamlets, 7 of which received the 3D-WDST and insecticidal nets (LLINs) as intervention and 7 received LLINs only as control in a two-arm cluster randomized controlled trial. Follow up studies on malaria infection, entomological parameters, ancillary social aspects, and cost-effectiveness were conducted during the 52 weeks follow up. Trial findings is expected to be released this year addressing the research gap on sustainable vector control approaches.

5211

EVIDENCE OF TRANSMISSION OF PLASMODIUM VIVAX 210AND P. VIVAX 247 BY ANOPHELES GAMBIAE AND AN. COLUZZII MAJOR MALARIA VECTORS IN BENIN

Aboubakar Sidick, Razaki Osse, Filemon T. Tokponnon, Gil Germain Padonou, Zinsou Come Koukpo, Bruno Akinro, Martin Akogbeto

Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

Historically, malaria in sub-Saharan Africa has been almost exclusively attributed to Plasmodium falciparum (Pf). Current diagnostic and surveillance systems in Benin are not designed to accurately identify or report non-Pf human malaria infections, resulting in a dearth of routine epidemiological data on their significance. This study aims to assess and compare the prevalence of circumsporozoite protein (CSP) antibodies of P.f, P. vivax (P.v) 210 and P.v 247 in An .gambiae s.l. in 24 communes of Benin. For that, mosquito collections were performed through human landing catches(HLC) and pyrethrum spray catches (PSC). For HLC, 384 collectors were used overnight while 240 bedrooms were used for PSC. Collected mosquitoes were morphologically identified, and P.f, P.v210 and 247 CSP antibodies were sought in An. gambiae s.l through the ELISA and polymerase chain reaction (PCR) . Of the 32773 collected mosquitoes, 20.9% (n=6857) were An. gambiae s.l, 3.9% (n=1292) An. funestus gr., and 0.6% (n=189) An. nili gr. Molecular species identification performed in An. gambiae s.l. revealed that, An. gambiae (53.68%) was the predominant species, followed by An. coluzzii (45.88%), and An. arabiensis (0.44%). In An. gambiae s.l., the sporozoite rate (SR) was 2.6% (95% CI: 2.1-3.1) for P.f, against 0.30% (95% CI: 0.1-0.5) and 0.2% (95% CI: 0.1-0.4) respectively for P.v 210 and P.v 247. P.f sporozoite positive mosquitoes were mostly An. gambiae (64.35%), followed by An. coluzzii (34.78%) and An. arabiensis (0.86%). At the opposite, for the P.v 210 sporozoite positive mosquitoes, An. coluzzii and An. gambiae accounted respectively for 76.92% (10/13) and 23.08% (3/13). Only An. coluzzii was found infected to P.v247. Overall, the present study shows that P. f is not the sole Plasmodium species involved in malaria cases in Benin. In addition, An. gambiae and An. coluzzii have different ability to get infected to the different identified Plasmodium species. These results will help the National Malaria Control Program to better plan the therapeutic management strategy of malaria cases to move towards the pre-elimination of the disease.

5212

MOSQUITOCIDAL ACTIVITY OF IVERMECTIN-TREATED NETTINGS AND SPRAYED WALLS ON ANOPHELES GAMBIAE

Majidah Hamid-Adiamoh[1], Abdul Khalie Muhammed[2], Benoit Sessinou Assogba[3], Harouna Massire Soumare[3], Lamin Jadama[3], Moussa Diallo[3], Mamadou Ousmane Ndiath[3], Umberto D'Alessandro[3], Alfred Amambua-Ngwa[3], Annette Erhart[3]

[1]Indiana University school of Medicine, South bend, IN, United States, [2]Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine,, Banjul, Gambia, [3]Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia

Ivermectin (IVM) has been proposed as a new tool for malaria control due to its mosquitocidal effect on malaria vectors when they blood feed on treated humans or cattle. Nevertheless, IVM may have a direct insecticidal effect on vectors when applied on bed nets or sprayed walls. We conducted a pilot study to measure the direct mosquitocidal effect of IVM on Anopheles gambiae. Laboratory-reared mosquitoes (Kisumu) were exposed to IVM on impregnated netting materials and sprayed walls (plastered and mud) at a determined discriminating dose using cone bioassays. Mosquito survival was assessed at 24, 48 and 72 hour post-exposure and compared with positive (deltamethrin (DM) and pirimiphos methyl) and negative (no insecticide) controls. Mosquitoes were also blood-fed either 12 hours pre- or post-exposure and monitored for oviposition. Hazard rates for IVM mortality was modeled using Cox proportional hazards model. Over 800 mosquitoes exposed to IVM discriminating concentration of 28mg/ml (2.8% w/v) died within 6 hours when exposed to IVM-treated nettings, within 18 hours for sprayed walls. Mosquito survival on the IVM-treated nettings was similar to that of DM-treated nettings. However, mosquitoes survived significantly longer on the IVM-sprayed walls (100% mortality at 18 hr) compared to positive control walls (100% mortality at 6 hr) (Log rank $X2 = 14.03$, $p<0.001$). The adjusted Cox model predicted a hazard rate of 0.24 (95% CI: 0.19-0.30; $p<0.001$) with IVM compared to DM or pirimiphos methyl. Moreover, a significant interaction was found between treatment and surface predicting a three-fold higher hazard with IVM-treated nettings [HR=3.1 (95% CI: 2.21-4.23); $p<0.001$] but not with IVM-treated plastered walls [HR=1.1 (95% CI: 0.7-1.7); $p=.077$]. IVM also inhibited mosquito blood feeding and oviposition regardless of exposure being pre-or post-feeding. Our findings confirm the direct mosquitocidal effect of IVM on An.

gambiae and suggest that IVM could be deployed as a new insecticide against malaria vectors together with the other currently used insecticides for long-lasting insecticidal nets and indoor residual spraying.

5213

IN SILICO ANALYSIS AND DESIGN OF A MOLECULAR CONSTRUCT TO TARGET THE BETA TUBULIN2 GENE IN ANOPHELES GAMBIAE

The increasing expansion of vector resistance to insecticides requires finding alternative control methods to achieve malaria elimination. Genetic control is one of the promising approaches to control malaria vectors. In the context of genetic control of malaria vectors, genes involved in reproduction are of crucial importance to replace or suppress a vector population. The search for male-specific transcripts and proteins could lead to a better understanding of testicular specificity signals, whether at the promoter level, at splicing, or during translation. The regulatory sequences of these genes can also be used in genetic control strategies to engineer gene drive systems to disseminate desired traits including pathogen resistance or sex distortion. Beta tubulin2, is one of the genes involved in gamete formation which could be further exploited to optimize the efficiency of genetic control methods under development. Here, we developed in silico, a molecular construct to target beta tubulin2 gene in Anopheles gambiae to interfere with mosquito fertility, basing on Drosophila beta tubulin2 gene which has three putative orthologs in An. gambiae (AGAP010929, AGAP008622 and AGAP008623). Specifically, this is to identify the ortholog of the beta tubulin2 gene in An. gambiae, and to design knockdown and knockout strategies of the beta tubulin2 gene with RNA interference and CRISPR Cas9 technology respectively. A double-stranded RNA of 154 nucleotides was generated for the knockdown and a guide RNA was designed to knockout AGAP008622 gene via the CRISPR/Cas9 strategy. All these designs will be introduced into the mosquito for an in vivo experimental study to characterize the beta tubulin2 gene function in Anopheles

IDENTIFICATION OF ODORANT CO-RECEPTOR GENE IN ANOPHELES GAMBIAE AND IN SILICO DESIGN OF STRATEGIES TO STUDY ITS FUNCTION IN A VECTOR CONTROL PERSPECTIVE

Grégoire Sawadogo[1], Andrew Hammond[2], Tony Nolan[3], Abdoulaye Diabate[1]

[1]Institut de Recherche en Sciences de la Santé (IRSS), Bobo-Dioulasso, Burkina Faso, [2]Imperial College London, London, United Kingdom, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The most effective strategies to control malaria aimed to prevent the mosquito from biting. The African malaria mosquito shows an incredible preference for humans over other sources of blood, a behaviour that is driven by olfaction and could be exploited for vector control. The odorant receptor co-receptor (ORCO) gene is an essential component in the insect olfactory system and may help drive human-specific odour preferences. To investigate the role of ORCO in host seeking behaviour, we carried out an in silico study with the objective to design strategies to study the function of gene coding for the olfactory co-receptor involved in Anopheles gambiae reception of smell. FlayBase database was used to identify the ortholog of orco gene in Anopheles gambiae. NCBI/BLAST, NCBI/CD-Search and FlayAtlas/MozAtlas databases were used respectively for sequences alignment, conserved domain search and genes expression profile search in order to confirm the orthology. To study the function of the gene, E-RNAi database was used to design a RNA interfering system and CHOPCHOP and Benchling databases were used to design a CRISPR/Cas9 strategy. Our study finds strong evidence to suggest that the ortholog of orco in Anopheles gambiae is Agam/or7, also known as AGAP002560. We designed two experimental approaches to further investigate the function of AGAP002560 based on RNAi knockdown or CRISPR/Cas9 knock-out using custom double string RNA or guide RNAs, respectively. To facilitate the experimental investigation of AGAP002560 knockout, we designed a donor plasmid for homology-directed repair to allow integration of a GFP expression cassette into the AGAP002560 gene. These results constitute an important step in the study of the function of Agam\or7 gene and may yield new approaches for mosquito population control.

MARK RELEASE RECAPTURE EXPERIMENT IN BURKINA FASO DEMONSTRATES REDUCED FITNESS AND DISPERSAL OF GENETICALLY-MODIFIED STERILE MALARIA MOSQUITOES

Adama Franck Yao[1], Abdoul-Azize Millogo[1], Patric Stephane Epopa[1], Ace North[2], Florian Noulin[3], Koulmaga Dao[1], Mouhamed Drabo[4], Charles Guissou[1], Souleymane Kekele[1], Moussa Namountougou[1], Robert Kossivi Ouedraogo[1], Lea Pare[1], Nourou Barry1[1], Roger Sanou[1], Haida Wandaogo[1], Roch K. Dabire[1], Andrew McKemey[5], Frederic Tripet[3], Abdoulaye Diabate[1]

[1]IRSS/DRO, Bobo Dioulasso, Burkina Faso, [2]Department of Zoology, University of Oxford, United Kingdom, [3]Centre for Applied Entomology and Parasitology, School of Life Sciences, Keele University, Staffordshire, United Kingdom, [4]Department of Life Sciences, Imperial College London, London, United Kingdom, [5]Department of Life Sciences, Imperial College London,, London, United Kingdom

Every year, malaria kills approximately 405,000 people in Sub-Saharan Africa, most of them children under the age of five years. In many countries, progress in malaria control has been threatened by the rapid spread of resistance to antimalarial drugs and insecticides. Target Malaria, is a research consortium that aims to develop and share new genetic mosquito control tools for integrated malaria control strategies. In July 2019, in Burkina Faso (BF), the consortium proceeded with the first release of a genetically modified (GM) strain of Anopheles coluzzii called Ac(DSM)2. The Ac(DSM)2, was created through backcrossing Ag(DSM)2 transgenic females from a previously-established early dominant embryo lethality-inducing strain. In June 2019, a large cohort of the strain was produced, sexed, and males dusted with fluorescent powder. A single release of 6,428 hemizygous Ac(DSM)2 males and 8,422 non-transgenic male siblings was conducted in the village of Bana (BF). After 17 days, 527 dusted males were collected from swarms and houses and Polymerase Chain Reaction analysis revealed 145 of these to be Ac(DSM)2 males. GM males were recaptured 50.8 - 497m and siblings 50.8 – 1,678m from the release point. A Bayesian approach showed, that GM males were found to have significantly shorter daily survival rates than their wild type siblings (0.55 - 0.63 vs 0.73-0.77 survival day-1) and were also less mobile (diffusion rates 11,200 - 20,100 m2day-1 vs 28,800 - 75,700 m2day-1). The male population size at the time of the release was estimated to be in the range 28,000-37,000. These results provide information about the fitness and behaviour of GM males released at the start of the rainy season. The first release of genetically modified mosquitoes in Sub-Saharan Africa is an important milestone towards future releases of more effective strains targeting the sibling species of the A. gambiae complex

Public places can be an important source of breeding habitats of Aedes aegypti, the main dengue vector, but data to support this evidence are missing in Africa. This study conducted to fill this gap for Ouagadougou, coincided with the COVID-19 pandemic and the consequent installation of handwashing stations (HWS). We investigated the abundance and diversity of water holding containers in some public places of Ouagadougou, including HWS, and assessed their contribution to Ae. aegypti immature stages proliferation. Between September and October 2020, water-holding containers were systematically inspected for Aedes mosquito immature stages in 61 public places of Ouagadougou. All collected immature mosquitoes were counted, identified to genus. Breeding containers abundance and preference were estimated and generalised mixed models were fitted to larval and pupal densities. A total of 924 containers that were considered suitable for Ae. aegypti breeding habitat were identified, of which HWS and tires had the highest proportions of positive containers (37.42% and 37.27% respectively), followed by small containers (SC) (13.03%). At its peak, 44.73% and 41.02% of the total production (produced by all type of containers encountered in public places) of Ae. aegypti larvae and pupae, respectively were produced by HWS. Tires, bucket/can/pot (BCP) and SC followed in terms of larval and pupae productivity. Additionally, some containers were hosting immatures of non-Ae. aegypti mosquito species, including Anopheles gambiae s.l. and Culex species. In conclusion, containers in public places contribute to increase Ae. aegypti immatures densities in Ouagadougou and should be taken into account for dengue control. The major role of newly introduced HWS in Ae. aegypti immatures productivity recommends risk assessment prior to introduction of new tool in the public areas.

RETHINKING INSECTICIDE TREATED NET (ITN) DISTRIBUTION: A REVIEW OF CURRENT DISTRIBUTIONS SYSTEMS, COSTINGS AND CHALLENGES

Jane E. Miller[1], Hannah Koenker[2], Josh Yukich[3], Keith C. Esch[1], Lilia Gerberg[4], Keziah L. Malm[5]

[1]PSI, Washington, DC, United States, [2]Tropical Health, Baltimore, MD, United States, [3]Tulane University, New Orleans, LA, United States, [4]President's Malaria Initiative, USAID, Washington, DC, USA, Washington, DC, United States, [5]NMEP, Accra, Ghana

While malaria cases and deaths reduced steadily between 2000 and 2009, continued progress has stalled in parallel with annual funding gaps. To optimize the impact of continued limited resources, there is an even greater need to maximize the efficient, effective, and equitable targeting and use of malaria vector control strategies. Countries where malaria is endemic must be able to identify and deploy an optimal mix of vector control interventions suited to their local context, established priorities, and available resources. Insecticide Treated Net distribution through mass campaigns have been the mainstay of vector control interventions for over 20 years. Mass campaigns and continuous distribution channels have delivered over 2.2 billion nets in Sub-Saharan Africa and have been largely responsible for the impressive declines in malaria morbidity and mortality since 2000. However, many factors require new thinking and flexible approaches to ITN distribution including inadequate and inequitable targeting resulting in many households receiving nets they may not need or use while others remain without access, increasing insecticide resistance requiring more expensive nets with dual actives, challenges with durability with nets not lasting as long as expected, decreasing compliance with use particularly in urban areas and increasing fatigue from some partners for mass campaigns. These factors, combined with funding gaps and human resource constraints, necessitate a rethinking of ITN distribution through mass campaigns with a renewed focus on the alternative distribution mechanisms. Findings from a modelling study of continuous distribution versus mass distribution in Tanzania, costings studies of cost per net delivered (mean USD 6.29) from continuous distribution activities in four countries, durability monitoring data showing the period between net receipt and use, and findings from scaling up from pilots to national scale school-based distribution will be presented in order to highlight some of the factors to be considered in order to optimize ITN coverage, increase use, and maximize the impact of available funds.

ASSESSING INSECTICIDE RESISTANCE IN TWO MALE-BIASED ANOPHELES GAMBIAE S.L. TRANSGENIC STRAINS

Mark Q. Benedict[1], Katelyn Cavender[1], Benjamin Lee[1], Keri O. Harp[1], John B. Connnolly[2], Priscila Bascunan[1], Ellen M. Dotson[3]

[1]CDC Foundation, Atlanta, GA, United States, [2]Department of Life Sciences, Imperial College London, Ascot, United Kingdom, [3]CDC, Atlanta, GA, United States

The transgenic (TG) mosquito insecticide susceptibility must be determined, in comparison to that of the wild-type (WT), as part of the risk analysis performed prior to their release into the natural environment. Increased resistance could make the TG mosquitoes more difficult to control or could introduce novel resistance levels or mechanisms into the wild mosquitoes. A strain of Anopheles coluzzii, BF_Ac(PMB)1, and one of Anopheles gambiae, UG_Ag(PMB)1, contain a transgene that biases the sex ratio of progeny from TG fathers to > 95% males. These strains were previously developed by repeatedly backcrossing the transgene from Ag(PMB)1 into a WT strain of A. coluzzii from Burkina Faso (BF_Ac(WT)) or a WT strain of A. gambiae from Uganda (UG_Ag(WT)). This study compared TG mosquitoes to their WT counterparts for each introgressed strain. The insecticide susceptibility of females was determined using the standard World Health Organization (WHO) adult insecticide exposure kits and discriminating doses recommended by the WHO. The panel of insecticides included four pyrethroids (alpha-cypermethrin, lambda-cyhalothrin, permethrin, and deltamethrin), a carbamate (bendiocarb), an organophosphate (fenitrothion), and an organochlorine (DDT). Exposures were for 1 h except for fenitrothion which was for 2 h, as recommended by WHO. Mortality was determined 24 h later. Larvae were also exposed to a larvicide that is widely used in Africa, temephos, to determine susceptibility to that insecticide. TG females showed no increases in resistance to eight different insecticides representing four different classes when compared with their WT controls for either strain. When any resistance to insecticides was observed, it was detected in both TG and WT individuals for either strain. Overall, our data demonstrate the transgene has no effect on insecticide resistance for the two transgenic strains tested under the study conditions tested. Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the U.S. Centers for Disease Control and Prevention.

ASSESSING VECTOR COMPETENCE FOR PLASMODIUM FALCIPARUM AND O'NYONG-NYONG VIRUS IN A MALE-BIASED ANOPHELES COLUZZII TRANSGENIC STRAIN

Keri O. Harp[1], Vincent Nyasembe[1], Katelyn Cavender[1], Claire Schregardus[1], Benjamin Lee[1], John B. Connolly[2], Priscila Bascunan[1], Ellen M. Dotson[3]

[1]CDC Foundation, Atlanta, GA, United States, [2]Department of Life Sciences, Imperial College London, Silwood Park, United Kingdom, [3]CDC, Atlanta, GA, United States

Anopheles mosquitoes vector the etiological agents of important diseases including malaria and O'nyong-nyong virus (ONNV) fever. Because insecticide resistance levels are rising in vector populations, alternative control tools are urgently needed. A promising approach is the use of transgenic (TG) mosquitoes to suppress or modify wild populations. Before such TG mosquitoes can be considered for testing in the field, potential risks to the environment or health caused by their release must first be assessed. As part of a wider vector control development program,

we assessed the impact of a male-biasing transgene introgressed into an Anopheles coluzzii strain from Burkina Faso on vector competence for Plasmodium falciparum and ONNV. Previously, we have shown no significant difference in P. falciparum vector competence in TG females compared to their wild-type (WT) counterparts. In the current study, we determined if a potential reduction in egg production, a phenotype previously observed in females that mate with TG males, affects the P. falciparum infection rates by comparing infection rates in females from two crosses: 1) WT females x TG males, and 2) WT females x WT males. No significant differences were observed between groups (P > 0.05), in terms of oocyst counts 7 days post-infectious blood meal (d pIBM) (median WT: 21, TG: 25), with a slight significant reduction in prevalence in cross 1 (1= 91.3%, 2=97.5%, P: 0.047). Also, no significant increase in sporozoite intensity or prevalence at 11 and 15 d pIBM was seen in either group. For ONNV, the infection, dissemination, and transmission potential rates of TG females were compared to that of WT females. No significant difference was found in the three parameters measured between the two groups. Overall, our data suggest no effect of the transgene, the genetic background or the reduced fecundity on P. falciparum infection rates or ONNV infections for any of the parameters analyzed. Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the U.S. Centers for Disease Control and Prevention.

MOLECULAR AND BIOINFORMATIC CHARACTERIZATION OF THE INTROGRESSION OF A MALE-BIASED TRANSGENE INTO A UGANDAN LOCAL WILD-TYPE STRAIN

Katelyn Cavender[1], Keri O. Harp[1], Benjamin Lee[1], **Priscila Bascunan**[1], Ellen M. Dotson[2]

[1]CDC Foundation, Atlanta, GA, United States, [2]CDC, Atlanta, GA, United States

To ensure that a transgenic mosquito strain that may eventually be released into the field reflects that of the wild population, a transgene from a founding transgenic strain generated in a laboratory line, is then introgressed into genetic backgrounds of colonies recently established from the field?. However, alleles potentially associated with adaptations to laboratory rearing conditions and to the transgene flanking regions may be inherited with the selected locus to[LAE(1] [BGA(2] the introgressed strain, even when they are separable by recombination. Ag(PMB)1 is a transgenic Anopheles gambiae strain that during male spermatogenesis expresses the I-PpoI variant W124L fused to eGFP, leading to approximately 95% male offspring. The subsequent introgression of the PMB1 transgene into an A. gambiae s.s wild-type (WT) strain from Uganda (UG_Ag(WT)) led to the generation of the UG_Ag(PMB)1 strain. This study describes the introgression process and the molecular characterization of the introgression after six repeated backcrosses of Ag(PMB)1 transgenic females with UG_Ag(WT) males. Life-history traits (i.e. egg yield, hatching rates, etc.), SNP genotyping analysis via KASP assays, and 2La inversion analysis via PCR were conducted. The recorded life-history traits revealed that the newly introgressed strain UG_Ag(PMB)1 is robust and demonstrated sufficient rates in terms of egg yield, hatching, and pupal eclosion to maintain and amplify the colony under lab conditions. Preliminary SNP analyses suggest that the introgressed strain has a similar genotype profile to the UG_Ag(WT) strain for the X and 3L chromosomes, while chromosome 2L carries allelic forms from both parentals. Finally, the 2La genotyping showed that both arrangements of the 2La inversion are present in the WT parental and the introgressed strain. Overall, this study presents a phenotypic and molecular characterization of the PMB1 transgene introgression process into the genetic background of a Ugandan WT strain after six backcrosses.

5221

MARK, RELEASE AND RECAPTURE EXPERIMENT OF A LABORATORY STRAIN OF ANOPHELES COLUZZII IN TWO VILLAGES IN MALI

Alahaye Mahamane Maiga[1], Sidy Doumbia[1], Amadou Guindo[1], Lakamy Sylla[1], Mohamed Moumine Traore[1], Bilkissou Yagoure[1], Nafomon Sogoba[1], Frederic Tripet[2], Mamadou B. Coulibaly[1]

[1]International Centre for Excellence in Research (ICER-Mali), Bamako, Mali, [2]Centre for Applied Entomology and Parasitology, School of Life Sciences, Keele University, Staffordshire, UK, Bamako, Mali

Regular surveys are usually carried out to understand the composition, structure, and abundance of vectors. However, these surveys do not make it possible to estimate the size of the vector population of the locality because the fraction of the people collected is not known. One of the most widely used methods of estimating population size is the “mark-release and recapture” method. Tagging, release, and recapture experiments were carried out in the villages of Tieneguebougou and Ouassorola in Mali for two consecutive years (August 2016, July 2017, and November 2017). For each experiment, approximately 5,000 adult male mosquitoes (Anopheles coluzzii) were released. Swarm sampling was the most productive method for collecting male mosquitoes in the field. The size of the population was estimated in Tiénéguebougou in August 2016 (106,103) greater than that observed in July 2017 (11,546) and November 2017 (29,227), this same phenomenon was observed in Ouassorola, the size of the population observed in August 2016 (90,674) is higher than that observed in July 2017 (19,046) and in November 2017 (19,559). The results of the three mark, release, and recapture experiments show a statistically significant difference between the recapture rates obtained in August 2016 (0.52%), July 2017 (2.07%), and November 2017 (1.09 %), this difference was also observed in the village of Ouassorola during August 2016 (1.78%), July 2017 (1.60%) and November 2017 (0.75%). The daily survival rate for Tieneguebougou is 0.26 in August 2016; 0.35 in July 2017 and 0.22 in November 2017 and that of Ouassorola: 0.35 in August 2016; 0.38 in July 2017, and 0.29 in November 2017. The average distance covered by males varied from 40 m to 100 m.

5222

MOLECULAR STRATEGIES TO DEPLOY SINGLET OXYGEN AS AN UNASSAILABLE BIOCIDE FOR DISEASE PREVENTION AND VECTOR CONTROL

Kwang Poo Chang[1], Joseph M. Reynolds[1], Dennis K.P. Ng[2], Jordy Y.H. Tu[3], Chia-Kwung Fan[4], Shin-Hong Shiao[5]

[1]Chicago Medical School/RFUMS, North Chicago, IL, United States, [2]Department of Chemistry, The Chinese University of Hong Kong, Sha Tin, New Territories, Hong Kong, China, [3]Department of Molecular Parasitology and Tropical Diseases, School of Medicine and Center for International Tropical Medicine, College of Medicine, Taipei Medical University,, Taipei, Taiwan, [4]Department of Molecular Parasitology and Tropical Diseases, School of Medicine and Center for International Tropical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan, [5]Department of Tropical Medicine and Parasitology National Taiwan University, Taipei, Taiwan

Singlet oxygen (1O2) is a potent biocide potentially deployable for integrated control of tropical diseases and their insect vectors. This is a very short-lived oxidative radial, but is highly destructive of cellular molecules when generated intracellularly. Parasites and insects are defenseless against 1O2. Only plants have evolved specific mechanism to detoxify 1O2 by necessity, as it is produced abundantly during photosynthesis. In the presence of atmospheric O2, exposure of certain dyes, e.g. porphyrins and phthalocyanines (PC) to light produces 1O2. Its half-life is only in the order of μs, necessitating its intracellular generation to feasibly harness its biocidal activity effectively. One example is genetic engineering of Leishmania to complement its inherent defects in porphyrin biosynthesis, resulting in cytosolic accumulation of abundant uroporphyrin 1 (URO). Another example is chemical engineering of PC for hydrophilicity and cationicity, facilitating its endocytosis by cells. Leishmania doubly loaded with cytosolic URO

and endosomal PC are inactivated by dim light to completion. These inactivated Leishmania preserved their natural vaccines and adjuvants with prophylactic activities against experimental leishmaniasis. Preliminary data further show the potential of 1O2 -inactivated Leishmania as a platform for safe and effective delivery of transgenically add-on vaccines against malignant and viral diseases in mouse models. Hydrophilic and cationic PC were also shown experimentally to represent a new type of light-activated insecticides, i.e. their mosquito larvicidal activities, featuring the requirement of dim light with <µM LD50 values. Similar results have been obtained by studying PC in additional laboratory insect models. A significant advantage has long been attributed to this type of insecticides, i.e. their aversion to selection of genetic variants for resistance. An additional advantage of PC is their excitability to produce insecticidal 1O2 by deep-penetrating red/IR light invisible to insects, thereby potentially increasing considerably the range and scope of targetable insect vectors.

5223

DISCOVERING NATURAL PRODUCT CHEMISTRIES FOR VECTOR CONTROL

Lide Bi[1], Maria Murgia[1], Shruti Sharan[1], Jasleen Kaur[1], William Austin[1], Lilly Wu[1], Lan Chen[1], Ameya Gondhalekar[1], Michael Scharf[2], Catherine Hill[1]

[1]Purdue University, West Lafayette, IN, United States, [2]University of Florida, Gainesville, FL, United States

Natural products (NPs) represent diverse chemical structures and, potentially, modes of action of vector control importance. NPs have inspired the development of multiple synthetic insecticides, suggesting the discovery of novel NPs for the development of highly effective insecticides needed to control insecticide-resistant vector populations. Here, we report two interdependent studies performed to identify novel mosquito-active insecticide leads with modes of action distinct from existing insecticides used in mosquito control programs. In the first study, we performed a high-content larval phenotypic screen using first instar larvae of Aedes aegypti against 3,680 compounds from the AnalytiCon MEGx Natural Product Libraries and a screening platform developed, as reported previously. Screening revealed five chemistries that caused larval mortality, including rotenone, the detection of which confirmed the ability of the screen to detect mosquito-active NP chemistries. 140 chemistries that caused atypical larval phenotypes, including cuticular pigmentation and morphometric changes relative to negative controls, were also identified by the screen. Some of these chemistries may act via disruption of pathways regulating mosquito melanization, growth and development, including potentially unique targets in the insect nervous systems, thus representing important opportunities for novel insecticide development. In the second study, we performed electrophysiological recordings using the suction electrode technique and ganglia of Blattella germanica to investigate the mode of action and impact on the insect nervous systems of metergoline and NP-1, two chemistries identified by HTP screening. Results suggested metergoline and NP-1 may act via serotonergic pathways and one or more conserved targets in the insect nervous systems, respectively, making them potential leads for the development of new insecticides that could be used to control insecticide-resistant populations. Results will be reviewed and future lines of research proposed in the context of new insecticide development.

5224

IMPACT OF USING DIFFERENT TYPES OF MOSQUITO TRAPS TO ASSESS ENTOMOLOGICAL EFFICACY OF DUAL-ACTIVE INGREDIENT LONG-LASTING INSECTICIDAL NETS (LLINS) IN BENIN

Boulais Yovogan[1], Arthur Sovi[2], Constantin Adoha[1], Bruno Akinro[1], Manfred Accrombessi[2], Razaki Ossè[1], Gil Padonou[1], Louisa Messenger[3], Armel Djènontin[1], Clément Agbangla[4], Corine Ngufor[2], Jackie Cook[2], Natacha Protopopoff[2], Martin Akogbéto[1]

[1]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]School of Public Health, University of Nevada, Las Vegas, NV, United States, [4]Faculté des Sciences et Techniques de l'Université d'Abomey-Calavi, Abomey-Calavi, Benin

Selection of mosquito sampling traps is of crucial importance to evaluate impact of vector control tools on entomological outcomes. During a cluster randomised control trial evaluating the relative efficacy of two dual-active ingredient (a.i.) nets compared to pyrethroid only nets, we assessed performance of different mosquito trap types: Human Landing Catch (HLC), CDC light traps, and Pyrethrum Spray Catch (PSC). Anopheles mosquitoes were collected with the three trap types in 4 houses in each of the 60 trial clusters at baseline and every quarter for 24 months using PSC and HLC, while CDC light traps were performed during two quarters only. The density of An. gambiae s.l and its Plasmodium falciparum sporozoite infection were assessed. Mean density of vectors collected per trap per night was the highest with HLC (15.9), followed by CDC light trap (6.8), with the PSC (1.1) collecting 10 times less mosquitoes than HLC. All three trap types showed that the lowest mosquitoes density was collected in the Interceptor G2® dual a.i. arm compared to the other arms, although only HLC and PSC demonstrated strong evidence of this due to a greater number of collection rounds than CDC light traps. Furthermore, CDC light traps and PSC measured similar reductions in SR and EIR* (*CDC light trap only) as compared to HLC between study arms. The broadly similar results between trap types suggest that the more ethically acceptable, cheaper and logistically simpler methods such as CDC light traps could be prioritised for use in large community trials for measuring efficacy of vector control tools.

5225

EFFICACY OF PYRETHROID-PYRIPROXYFEN AND PYRETHROID-CHLORFENAPYR LONG-LASTING IMPREGNATED NETS (LLINS) FOR THE CONTROL OF NON-ANOPHELES MOSQUITOES: SECONDARY ANALYSIS FROM A CLUSTER RANDOMIZED CONTROLLED TRIAL

Constantin J. Adoha[1], Arthur Sovi[2], Boulais Yovogan[1], Bruno Akinro[1], Manfred Accrombessi[2], Edouard Dangbénon[1], Gil G. Padonou[1], Louisa A. Messenger[3], Clément Agbangla[4], Corine Ngufor[2], Jackie Cook[2], Natacha Protopopoff[2], Martin C. Akogbéto[1]

[1]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University of Nevada, Las Vegas, NV, United States, [4]Université d'Abomey-Calavi, Abomey-Calavi, Benin

Failure to control nuisance of mosquitoes may potentially affect adherence to vector control tools. The present study compares the vector density of Culex spp and Mansonia spp across the two dual a.i. LLINs and the standard pyrethroid-only LLIN arms, and assessing the seasonality of these mosquito species. 85,723 Culex spp and 144,025 Mansonia spp were caught over the study period. The density of Culex and Mansonia reduced in all three arms over the study period. There was no evidence of a significant reduction of the indoor or outdoor density of Culex spp in either dual a.i. long lasting net arms as compared to the standard pyrethroid only net arm [(indoor DR=0.9 (95% CI: 0.4-2.4), p=0.8817 for the alphacypermethrin-pyriproxyfen LLIN, indoor DR=0.6 (95% CI: 0.2-1.5) p=0.2793 for the alphacypermethrin-chlorfenapyr LLIN]. No evidence for differential reductions between arms was observed for Mansonia spp. A high density of Culex spp was found both in rainy and dry seasons, while for Mansonia spp this was mainly observed during the rainy season. These results suggest that the novel insecticides on the dual a.i. LLIN did not have additional impact on these species, and that pyrethroids might still be effective on them. Further work is required to determine whether these species of mosquitoes have resistance to the insecticides tested in this trial.

5226

EFFICACY OF PIRIKOOL® 300 CS USED FOR INDOOR RESIDUAL SPRAYING ON THREE DIFFERENT SUBSTRATES IN SEMI-FIELD EXPERIMENTAL CONDITIONS

Behi Kouadio Fodjo

Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire

Vector control using insecticides is a key prevention strategy against malaria. Unfortunately, insecticide resistance in mosquitoes threatens all progress in malaria control. In the perspective of managing this resistance, new insecticide formulations are being urged to improve the effectiveness of vector control tools. The efficacy and residual activity of Pirikool® 300CS was evaluated in comparison with Actellic® 300CS in experimental huts at the Tiassalé experimental station on three substrates including cement wood and mud. The mortality, blood-feeding inhibition, exiting behaviour and deterrency of free-flying wild mosquitoes was evaluated. Bioassay cone assays with susceptible and resistant mosquito strains were conducted in the huts to determine residual efficacy. A total of 20505 mosquitoes of which 10979 (53.5%) wild female Anopheles gambiae were collected for 112 nights. Residual efficacy obtained from monthly cone bioassay was higher than 80% with the susceptible, laboratory-maintained Anopheles gambiae Kisumu strain from the first to the tenth study period on all three types of treated substrate for both Actellic® 300CS and Pirikool® 300CS. This residual efficacy on the wild Tiassalé strain was over 80% until the 4th month of study on all Pirikool® 300CS and Actellic® 300CS treated substrates. Overall 24-hour mortalities of wild free-flying An. gambiae s.l. which entered the experimental huts over the 8-months trial on Pirikool® 300CS treatment was 50.5%, 75.9% and 52.7% respectively on cement wall, wood wall and mud wall. The positive reference product Actellic® 300CS treatment induced mortalities of 42.0%, 51.8% and 41.8% on cement wall, wood wall and mud wall. Pirikool® 300CS has performed against resistant strains of An. gambiae s.l. using indoor residual spraying in experimental huts. It could be an alternative product for indoor residual spraying in response to the vectors' resistance to insecticides.

5227

MEASUREMENT OF OOCYST AND SPOROZOITE INFECTION RATES IN ANOPHELES GAMBIAE S.L. UNDER NATURAL CONDITIONS IN BANCOUMANA, MALI

The dynamics of mosquito infections play a central role in Plasmodium falciparum transmission and human infection rates, and can be considered as an endpoint in trials of transmission-interruption interventions like vaccines. Here we measured natural oocyst and sporozoite infection rates in wild-caught Anopheles gambiae s.l. Every month (Mar 2018-Jul 2019), a team collected mosquitoes in 63 households comprising 503 rooms, for 7,435 collections total (372-494 collections per month). Live mosquito collections using mouth aspiration were followed by pyrethrum spray collections of killed mosquitoes. Live Anopheles mosquitoes with recent bloodmeal were separated from unfed mosquitoes and kept seven days; midguts were dissected and oocyst infections were counted. Killed Anopheles mosquitoes were preserved in 80% ethanol and retained for ELISA-CSP (sporozoite infection rates) and PCR (Anopheles speciations). Collections yielded 4,089 live female Anopheles with an average density of 0.55 (SD = 0.84) per hut; 3,164 (77.4%) mosquitoes survived to dissection, oof which 84 (2.7%) were infected (2.7%) with mean of 2.1 oocysts [range 0-15]. Among 3,143 killed mosquitoes identified morphologically as An. gambiae s.l (mean 0.42 mosquitoes per hut), 25 (0.79%) were positive for CSP infection by ELISA. As expected, the highest number of infected mosquitoes (n=21) were collected during peak transmission season (Aug-Oct). A subset of mosquitoes underwent PCR analysis that identified two predominant species, An. coluzzii and An. arabiensis, at frequencies of 61.5% and 8.6% respectively. These large-scale collections provide an estimate of the incidence of malaria infection in circulating mosquito populations and can be a valuable tool to measure the impact of any malaria control measures tested or implemented in communities.

5228

EVALUATING MOSQUITO BEHAVIOR DURING EXPOSURE TO DIFFERENT INSECTICIDE-TREATED NETS (ITNS) USING VIDEO CONE TEST

Aaron Adjin Lartey[1], Jewelna Efua Birago Akorli[2], Abigail Serwaa Akoto Bawua[1], Godwin Kwame Amlalo[2], Samuel Sowah Akporh[2], Rebecca Pwalia[2], Ibrahim Kwaku Gyimah[2], Samuel Opoku Darkwah[2], Joannitta Joannides[2], Dominic Acquah-Baidoo[2], Akua Obenewaa Yirenkyi Danquah[2], Eleanore Sternberg[3], Samuel Kweku Dadzie[2]

[1]School of Public Health, University of Ghana, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [3]Tropical Health, Liverpool, United Kingdom

The increasing resistance of mosquitoes to the active ingredients in Insecticide treated Nets (ITNs) has created a need for the development of effective vector control methods and testing protocols. The Video Cone Test (VCT) builds on the World Health Organization (WHO) cone bioassay by incorporating a behavioural record of mosquito interactions with ITNs. The objective of this study is to assess the behavoioural traits of mosquitoes when exposed to various types of ITNs. To achieve this objective, the study involved exposing 2-5 day old Anopheles gambiae mosquitoes to different ITNs (PermaNet® 2.0, PermaNet® 3.0, and Olyset®) for varying lengths of time (1, 2, 3, 4, 5, and 6-minutes) using the WHO cone bioassay. During the process, mosquito behaviour was recorded using a smartphone, and the activities or movements of mosquitoes in different regions of the cone (Region-0, Region-1, Region-2 and Region-3) were depicted. After exposure, the mosquitoes were given a 10% sugar solution, and mortality was recorded 24 hours later. The study found significant differences in the number of activities observed in each cone region between the two mosquito strains ($p<0.05$), with Region-1 recording the highest activity in both strains. Olyset® did not exhibit any variation between the two strains in any of the regions ($p>0.05$), while PermaNet® 2.0 and PermaNet® 3.0 showed variations between the strains in Regions 1, 2 and 3 ($p<0.05$). Mortality was strongly associated with all regions of the cone ($p<0.00$), with Regions 2 and 3 showing the strongest associations (coefficients = 1.661457 and 1.35458, respectively). These results indicate that different types of ITNs have varying effects on mosquito behaviour. Furthermore, the WHO cone bioassay, with the addition of a camera component can provide valuable insights into mosquito behaviour.

5229

KEY ENTOMOLOGICAL AND MALARIA INDICATORS DURING THE PERIODS OF INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS-METHYL AND CLOTHIANIDIN-BASED PRODUCTS IN ZAMBIA

Mohamed Nabie Bayoh[1], Rabecca Ngwira[1], Chakulunta Nkweto[1], Nduka Iwuchukwu[1], Willy Ngulube[2], Reuben Zulu[2], Allison Belemvire[3], Paul Psychas[4], Daniel Impoinvil[5], Sameer Desale[6], Kelley Ambrose[6], Aklilu Seyoum[6]

[1]PMI VectorLink Project, Abt Associates, Lusaka, Zambia, [2]National Malaria Elimination Program, Lusaka, Zambia, [3]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [5]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]PMI VectorLink Project, Abt Associates, Rockville, MD, United States

Zambia deployed pirimiphos-methyl for IRS from 2013 -2018, before switching to clothianidin products from 2019 -2022, given its duration of efficacy was found to be >10 months compared to 4 -5 months for pirimiphos-methyl. The trends in entomological and malaria indicators were reviewed from 2015 -2018 and from 2019 -2022. This analysis investigates whether pirimiphos-methyl should be reintroduced for IRS in Zambia. We analyzed two available and complete entomological indicators—indoor density (ID) and human biting rate (HBR)—collected in 10 sentinel sites from 2015 -2022, as well as annual malaria incidence rates in 116 districts from 2013 -2022. Only one out of the 10 sites had entomological monitoring

data covering the deployment periods of both insecticides; the rest of the sites covered only one of the periods. Mixed effect models were used with random intercept per site and insecticide as fixed effect controlling for the month of collection and rainfall. We found no significant differences in ID and HBR between the pirimiphos-methyl versus clothianidin periods for either An. gambiae s.l. (ID 0.45 vs 0.53, p=0.8141, HBR indoor 1.31 vs 3.81 p=0.8686, HBR outdoor 1.71 vs 3.37 p=0.1612) or An. funestus s.l. (ID 2.70 vs 2.84 p=0.9817, HBR indoor 11.29 vs 19.09 p=0.7912, HBR Outdoor 8.37 vs 9.93 p=0.9664). The malaria incidence rate was significantly lower for pirimiphos-methyl (496.6 per 1,000) compared to clothianidin (613.2 per 1,000) (p<0.0001). This preliminary investigation indicates that the change from pirimiphos-methyl to clothianidin products did not result in a reduction in vector numbers despite the difference in duration of efficacy while malaria incidence rates increased during the period of clothianidin deployment. While these results suggest that pirimiphos-methyl could be safely reintroduced into the IRS insecticide rotation with no significant adverse effect on program outcomes, more analyses controlling for other confounders are still needed.

5230

MOSQUITO TRAPPING BEDNET (T-NET) FOR INSECTICIDE RESISTANCE MANAGEMENT AND MALARIA CONTROL

Chouaibou S. Mouhamadou

CSRS, Abidjan, Côte D'Ivoire

Malaria burden is increasing. An estimated 241 million de cases and 627 000 deaths occurred worldwide in 2020. About 228 million cases were recorded in 2018 while in 2017, the WHO reported 219 million cases and 435,000 related deaths comparing to 216 million cases reported in 2016, which had already increased about 5 million cases over 2015. This situation is problematic and highlights the urgent need to develop new malaria control strategies. The widespread insecticide resistance in malaria vectors is considered as the principal reason why the LLINs along with IRS which have been critical to malaria prevention, are now failing to control the disease. To overcome this problem, we have developed a mosquito trapping bednet, the so-called T-Net which has the particularity to trap and kill mosquitoes regardless of their insecticide resistance status. Field testing in WHO-recommended experimental huts in Africa showed a 4.3-fold greater trap-kill rate of insecticide-free T-Net compared to Permanet 2.0, the most common bednet in Africa. A T-Net population model developed from field data to predict community-level mosquito control showed that the insecticide-free T-Net under field conditions against pyrethroid resistant mosquitoes was 12.7-fold more efficacious than single chemical, pyrethroid-treated nets. The current presentation covers recent findings (currently ongoing studies) in experimental huts comparing the efficacy of treated and untreated T-Nets versus PBO bednets considered by the WHO as reference for vector control and the prevention of malaria in insecticide-resistant areas.

5231

VALIDATION OF A METHOD FOR DRY PRESERVATION AND REHYDRATION OF ANOPHELES GAMBIAE SENSE LATO FOR PARITY ANALYSIS TO ASSESS IMPACT OF VECTOR CONTROL MEASURES IN THE FIELD

Elizabeth Pretorius, Mojca Kristen, John Bradley, James G. Logan, Anna Last, Robert Jones

London School of Hygiene and Tropical Medicine, London, United Kingdom

The control of malaria is still heavily dependent on mosquito control interventions. With progress in malaria control stalling in recent years, it is essential to understand the impact of interventions on vector populations. Age grading is a valuable method for determining whether interventions alter the age structure of target mosquito populations, but current methodologies are logistically challenging to incorporate into clinical trials and routine surveillance. We validated a method for dry preserving mosquitoes using silica gel and rehydrating prior to parity assessment using the ovarian tracheation method. Lab-reared Anopheles coluzzii mosquitoes with known parity-status were dry-preserved in silica gel for 1, 2, 6, 9 and 12 weeks, and rehydrated prior to parity assessment. Results were compared to parity results from freshly-killed mosquitoes from the same colony. Following lab validation, field-caught An. gambiae s.l. from the Bijagós Archipelago, Guinea-Bissau, were assessed by three different assessors who were blinded to each other's scores. Inter-rater reliability (IRR) was calculated for all assessor-pairings, and an overall index of agreement was calculated using the arithmetic mean of these IRRs. The impact of time preserved was investigated using a one-way ANOVA to look for differences in assessor agreement over three timeframes; (1) 16-70 days (2) 71-90 days and (3) 91-110 days. When dry-preserved and rehydrated, the parity status of 90.1% of insectary-reared An. coluzzii were correctly identified compared to 97.8% in freshly-killed mosquitoes. IRR of freshly-killed An. coluzzii was highest (0.94). Results at all time points showed excellent strength of agreement between assessors. For field-caught An. gambiae s.l., the overall index of agreement between all three assessors was 0.86 (95% CIs 0.78-0.93) indicating an almost perfect agreement. Dry preserving and rehydrating Anopheles mosquitoes to assess the efficacy of a control intervention provides an excellent and feasible alternative to using freshly-killed mosquitoes in remote settings where standard methodologies are logistically infeasible.

5232

IN SILICO DESIGN OF MOLECULAR MODEL TO STUDY THE SIFAMIDE GENE FUNCTION IN ANOPHELES GAMBIAE OLFACTORY SYSTEM, IN A PERSPECTIVE OF GENETIC CONTROL OF THE VECTOR

Achaz-Achim Mawugnon Agolinou[1], Aboulaye Diabaté[1], Tony Nolan[2], Andrew Hammond[3], Roberto Galizi[4], Diego Giraldo[5]

[1]Institut de Recherche en Sciences de la Santé, Direction Régionale de l'Ouest (IRSS-DRO), Bobo Dioulasso, Burkina Faso, [2]Liverpool School of Tropical Medicine (LSTM), Liverpool, United Kingdom, [3]Imperial College London, Liverpool, United Kingdom, [4]Keele University, Newcastle-under-Lyme, Staffordshire, United Kingdom, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Despite decades of control effort, malaria still cause a public health problem. Fortunately, the main vector of the disease Anopheles gambiae has a weakness: it uses its sense of olfaction to target the human host on which feed. Several genes including SIFamide regulate this behaviour in the vector. The overall objective of this study is to develop in silico strategies to access the function of the SIFamide in An. gambiae. For this purpose, the EnsemblMetazoa database was used to identify the orthologue in the mosquito. Then, tools such as BLAST-NCBI, CD-Search, FlyAtlas2 and MozAtlas was used to confirmed this orthologue using Drosophila melanogaster as reference. Also, a knockout model was generated in silico for the orthologue by using CRISPR-Cas9 technology with the CHOPCHOP and Benchling tools. The orthologue identified is AGAP007056. The similarity and identity percentages between the protein and nucleotide sequences, demonstrate the conservation of the gene in insects. Similar expression pattern of the gene was found in An. gambiae and Drosophila melanogaster tissues but appears to be more expressed in the male than female. This could be explained by the fact that the male feeds exclusively on nectar and needs a regular supply of sugar for its survival. Otherwise, the absence of a protein domain could be due to a lack of annotation or that the gene really doesn't have a domain that has remained conserved through evolution. For the knockout technology, the gRNA has 20 bp in size and an efficiency score of 66.62%. It targets a conserved region of exon 2 and [%GC] = 65. The plasmid used for homology repair contains basis features such as a green fluorescent protein flanked by homology arms (1500 bp) immediately upstream and downstream of the Cas 9 cleavage site. Our constructions shown a good efficiency as demonstrate by the e-values less than 0.05. Better understand the phenotype associated to SIFamide expression will allow us to select this trait in a gene drive approach or other strategies targeting the same process in the vector.

5233

A SEMI-FIELD EVALUATION OF THE USE OF HUMAN LANDING CATCHES VS HUMAN-BAITED DOUBLE NET TRAPS FOR ASSESSING THE IMPACT OF A VOLATILE PYRETHROID SPATIAL REPELLENT AND PYRETHROID-TREATED CLOTHING ON ANOPHELES MINIMUS LANDING

Elodie Vajda[1], Manop Saeung[2], Amanda Ross[3], David McIver[1], Allison Tatarsky[1], Sarah J. Moore[4], Neil F. Lobo[5], Theeraphap Chareonviriyaphap[2]

[1]University of Califonia, San Francisco, San Francisco, CA, United States, [2]Kasetsart University, Bangkok, Thailand, [3]University of Basel/Swiss TPH, Basel, Switzerland, [4]Ifakara Health Institute, Bagamoyo, Tanzania, United Republic of, [5]University of Notre Dame/University of Califonia, San Francisco, Notre Dame, IN, United States

The mosquito landing rate measured by human landing catches (HLC) is the conventional endpoint used to evaluate the impact of vector control interventions on human-vector exposure. Non-exposure based alternatives to the HLC are desirable to minimize the risk of accidental mosquito bites during evaluations. One such alternative is the human-baited double net trap (HDN), but the estimated personal protection of interventions using the HDN has not been compared to the efficacy estimated using HLC. This study evaluates the performance of the HLC and the HDN for estimating the effect on mosquito landing rates of two intervention types characterized by contrasting modes of action, a volatile pyrethroid spatial repellent (VSPR) and insecticide-treated clothing (ITC). Experiments were performed to estimate the impact of both interventions on mosquito landing using the two methods. A block randomized cross-over design was carried out over 32 nights with both the HLC and HDN. Eight replicates per combination of collection method and intervention or control arm were conducted. For each replicate, 100 Anopheles minimus were released and were collected for 6 hours. For the VPSR, the estimated effect was similar for both methods; when measured by HLC (OR 0.007 95% CI (0.005, 0.01) p<0.001) and by HDN (OR 8.72e14 (0, Inf) p = 0.99), and no mosquitoes were recaptured by HDN. For the ITC, the protective efficacy was measured by HLC (OR 0.30 (0.23, 0.40) p<0.001), but there was no evidence of protection when measured by HDN (OR 1.04 (0.85, 1.27) p=0.69). Interplay between mosquitoes, bite prevention tools, and the sampling method result in vector behaviour changes which may impact the estimated protective efficacy. Consequently, sampling method must be considered when evaluating these interventions. The HDN is a valid alternative trapping method (relative to the HLC) for evaluating the impact of bite prevention methods that affect mosquito behaviour at a distance (e.g., VPSR), but not for interventions that operate through tarsal contact (e.g., ITC).

5234

FIRST EVIDENCE OF THE PRESENCE OF THE WOLBACHIA AND MICROSPORIDIES MBITA IN NATURALS POPULATIONS OF ANOPHELES GAMBIAE IN SOUTH OF BENIN

Anas Sidick[1], Juvenal Ahouandjinou[1], Wilfrid Sewade[1], Razaki Osse[2]

[1]Institut de Recherche pour le Developpement, Cotonou, Benin, [2]CREC, Cotonou, Benin

The Wolbachia endosymbiont can have major effects on the reproductive capacity and vectorial capacity of host insects and can be tools to control mosquito-borne pathogens. Anopheles gambiae sl is the main vector of malaria in Africa, but the use of Wolbachia in this species has been limited by difficulties in establishing stable transinfected lines and uncertainty surrounding native infections. The presence of Wolbachia and microsporidia have never been reported in An. gambiae sl in Benin. For this study, we searched for the presence of Wolbachia and Mbita(MB) microsporidia in natural samples of An. gambiae sl. infected or not with plasmodium falciparum collected in southern Benin (Cotonou, Porto-Novo, Calavi) over a period of 6 years. Our results showed that Wolbachia is present at a low prevalence in the natural population of An. gambiae sl. Of 8435 samples analyzed, only 29 were positive for Wolbachia by nested PCR representing 0.34% prevalence. No positive samples were found with regular PCR. However, MB microsporidia were present at a high proportion of 20.62% or 1740 positives out of 8435. The results also showed a very low prevalence of Wolbachia and microsporidia on samples positive for Plasmodium falciparum, respectively 0.33% (1/296) and 1.68% (5/296). The absence of a positive sample with regular PCR is encouraging for applications using Wolbachia-transinfected mosquitoes for malaria control. These results will also enable the National Malaria Control Program to diversify the methods of combating malaria.

5235

LABORATORY AND SEMI-FIELD EVALUATION OF BIO-EFFICACY AND PHYSICAL INTEGRITY OF OLYSET PLUS AND INTERCEPTOR G2 NETS AFTER THREE YEARS OF FIELD USE IN TANZANIA

Salum Azizi[1], Njelembo Mbewe[2], Baltazari Manunda[1], Amandus Joram[1], Natacha Protoppopof[2], Jackline Martin[2], Franklin Mosha[1], Johnson Matowo[1]

[1]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Long-lasting insecticidal nets (LLINs) provide protection against malaria vectors by its residual insecticidal activity even when its fabric is torn. Usage and washes during the LLIN's lifetime could result into loss of insecticidal component to an extent where users can be subjected to high risk of malaria transmission. To sustain gains in malaria control, LLINs should maintain high bio-efficacy and fabric strength for at least 3 years post distribution. Mortality and blood feeding inhibition (BFI) induced by 3 years old used Interceptor G2 (IG2) and Olyset plus (OP) LLINs were assessed following WHO guidelines at both laboratory and semi-field experimental hut trial. Both IG2 and OP LLINs were able to induce significant mortality and BFI to mosquitoes compared to the untreated LLIN (negative control). In cone bioassay, mortality induced by OP nets decreased significantly (50%, 46.3%) with washes and community usage respectively against susceptible Kisumu strain, compared to IG2 (10%, 11.25%). Higher mortality and BFI were induced by IG2 LLIN than OP LLIN in laboratory tunnel tests (against Kisumu strain and pyrethroid resistant Anopheles gambiae Muleba-Kis), and semi-field experimental hut trial against pyrethroid-resistant An. arabiensis. However, the difference was not statistically significant. Similarly the bursting and tensile strengths, mesh size and fabric weight of the IG2 LLIN were higher than that of the OP LLIN with a decreasing trend from unwashed, laboratory washed to community usage. In general bio efficacy and fabric strength of IG2 LLIN was higher than that of OP LLIN. National malaria control programs should consider both bio-efficacy and fabric integrity of different types LLINs prior to LLINs procurement and LLIN replacement.

5236

CRYOPRESERVATION AND THE OPTIMIZATION OF THE DEVELOPMENT OF WOLBACHIA IN THE CULEX PIPIENS MOSQUITO CELLS

Bryan King, Cheolho Sim

Baylor University, Waco, TX, United States

Wolbachia is common in insects and is an intracellular, maternally transmitted bacterium symbiont. These endosymbiotic bacteria can be mutualistic by, for example, enhancing their host's nutrition and modifying immune responses to improve survival rates. Wolbachia can also act as a parasite by taking resources from their host to boost survival or by influencing host reproduction to increase their potential to proliferate in the host population. Wolbachia has recently been utilized to sterilize male mosquitoes for population control, but little is known about how it interacts with certain traits like diapause. An essential biotechnological tool for both fundamental and practical research is the insect cell culture system. This work's goal was to demonstrate the usage of a Culex cell line for multiplying

Wolbachia and developing a cryopreservation process to increase the number of Wolbachia to be utilized for diapause research and storing for prolonged use.

HOST-FEEDING PREFERENCES AND TEMPERATURE SHAPE THE DYNAMICS OF WEST NILE VIRUS: A MATHEMATICAL MODEL ENDEAVOR

Suman Bhowmick, Dr. Rebecca Lee Smith

Department of Pathobiology, UIUC, Urbana-Champaign, IL, United States

Host-feeding preferences and temperature shape the dynamics of West Nile virus: a mathematical model endeavour Suman Bhowmick1, Rebecca Lee Smith11,2,31 1 Department of Pathobiology, University of Illinois, Urbana-Champaign, Urbana,I llinois, USAsumanb@illinois.edu2. Carl R. Woese Institute for Genomic Biology, University of Illinois, Urbana-Champaign, Urbana, Illinois, USA 3. Carle Illinois College of Medicine, University of Illinois, Urbana-Champaign, Urbana, Illinois, USA

West Nile virus (WNV) is the leading cause of mosquito-borne disease in the United States. It is most commonly spread to people by the bite of an infected mosquito. The impact of WNV on human health is widely predicted to increase in coming years as the temperature warms, since mosquito biology and disease ecology are strongly linked to environmental conditions. However, direct evidence linking these changes to the traits of mosquito and the ecological mechanisms that may underpin such changes are poorly understood topics. Transmission of WNV within the host community primarily is predicted by the relative abilities of the host to maintain and disseminate the virus and different eco-environmental factors. Related to that ability, there is an increase of evidence that shows strong preferences by mosquitoes for certain host species can dictate the dynamics of WNV and potentially govern the spill-over into mammals, such as humans, horses, and dogs. We have developed a mechanistic transmission model for WNV in one vector species (Culex pipiens) and preferred avian hosts based weather driven mosquito traits. Sensitivity analysis has revealed that feeding preference is one of the most influential parameters on intensity and timing of peak WNV infection. Our studies show that heterogeneous contact rates induced by host preference are a key factor in the WNV epizootics in multi-species host communities.

5238

CHARACTERIZATION OF ANOPHELINE SWARMS DURING THE DRY SEASON ALONG THE NIGER RIVER, MALI

Moussa Keita, Nafomon Sogoba, Ibrahim Sissoko, Alassane Dit Assitoun, Daouda Ouologuem, Mahamadou Diakite, Seydou Doumbia

Malaria Research and Training Center(MRTC), Bamako, Mali

Previous studies in Mali have implicated riverbeds as malaria hotspots during the prolonged dry season. These Anopheline populations found on riverbeds sustain malaria transmission throughout the dry season. They also serve as inoculums for both the transmission and the spread of insecticide resistance in surrounding areas at the onset of the rainy season. Mosquito swarm physical destruction is an alternative control intervention to reduce insecticide-resistant vector population density. This study aims to characterize the swarming behavior of Anopheline populations during the dry season. This is in the prelude to their physical destruction as a control intervention along the Niger River in Mali. We conducted an active search for Anopheline swarms, starting 30 minutes before sunset during 3 successive days in and around each fishing hamlet located along the Niger River. For each detected swarm, the following characteristics were recorded: type of marker, height, size, and coordinates of the markers. In the fishing hamlets along the river, there were 84 swarming places. The main type of swarm markers was related to anthropogenic activities and included bundles of wood for cooking (30.8%), bare ground (29.1%), piles of garbage (12.8%), walls (12.8%), latrines (5.1%), and brick (4.3%). The mean number of Anopheles specimens per swarm was 31.5 (Min = 5; Max = 120). Most of the swarms were located outside human settlements. The mean height of swarming was 2.0 meters (Min = 1m, Max = 3.5m) above the ground. This study showed that most of the swarming markers were created by anthropogenic activities and were located outside of human dwellings making them easily accessible for destruction.

5239

PREVALENCE OF BORRELIA BURGDORFERI SENSU LATO-INFECTED IXODES SCAPULARIS TICKS IN THE UNITED STATES AND CANADA: A COMPREHENSIVE REVIEW

Patrick H. Kelly[1], Ye Tan[2], Qi Yan[2], Julie Davis[3], James H. Stark[4]

[1]Pfizer, New York City, NY, United States, [2]Pfizer, Collegeville, PA, United States, [3]Clarivate, Cambridge, MA, United States, [4]Pfizer, Cambridge, MA, United States

Increasing densities and geographic expansion of Ixodes scapularis, the primary vector of Borrelia burgdorferi sensu lato (Bbsl), poses new risks for Lyme disease (LD). The objective of this review was to summarize tick surveillance data reported in high LD endemic areas in the US and Canada with a focus on the prevalence of Bbsl-infection in I. scapularis ticks. We conducted a literature search in PubMed from 2006 to 2023 to identify studies reporting on Bbsl-infection prevalence in questing I. scapularis ticks. Data were excluded if they were from low endemic regions (western and southern US, and western Canada), larvae, non-I. scapularis species, and studies collecting less than 50 ticks. Bbsl-infection prevalence was calculated as the number of ticks infected divided by the number of ticks tested. Descriptive analyses were performed to estimate the prevalence of Bbsl-infected I. scapularis ticks, stratified by country, surveillance type, tick life stage, and region. Of 3169 articles identified, 76 met inclusion criteria. A total of 239,161 ticks (n=156,107 in US; n=83,054 in Canada) collected between 1998-2019 were included in the analyses from 81 datasets (US=48; Canada=33). Overall, the mean prevalence of Bb-infected questing ticks was higher in the US than Canada (25.4% vs 22.3%; p<0.0001). Comparing regions and tick life stages, the mean prevalence of Bbsl-infected questing nymphs (21.1%) and adults (50.2%) in the US Northeast were significantly higher compared to those in the US Midwest (nymphs=17.7%; adults=34.7%) or Canada (nymphs=10.7%; adults=32.0%) (nymphs p=0.013; adults p=0.001). Increasing trends in the prevalence of Bbsl-infected questing ticks were observed from longitudinal data in both countries. Overall, the data reveal that the prevalence of Bbsl-infected I. scapularis ticks is high throughout high-endemic LD areas in the US and Canada. Regular assessment of densities of Bbsl-infected ticks in these areas is useful to understand the changing trends of tick infection prevalence and increasing LD incidence.

5240

THE POSSIBLE MICROBIAL ETIOLOGY OF ALZHEIMER'S DISEASE AND RELATED DEMENTIA

Remi L. Landry, Monica E. Embers

Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Neurocognitive disorders are sporadic, age-related, and hereditary conditions that can lead to multiple outcomes such as progressive cognitive impairment, psychiatric and behavioral disorders, and declines in daily life functions. Observational, epidemiological, experimental, and pathological studies have generated evidence for the possible polymicrobial causality in dementia-inducing diseases. The microbial hypothesis states that pathogens and microbes act as triggers, interacting with genetic factors to initiate the accumulation of beta-amyloid plaques, hyperphosphorylated tau protein, immunosuppression, and inflammation in the brain. Evidence indicates that Borrelia spp., HSV-1, treponemal spp., Chlamydophila pneumoniae, Candida albicans, and others can lead to cytokine dysregulation, alterations in brain biochemistry and neurotransmission, neuronal degeneration, and neural death. These effects, usually manifested during aging, accumulate over time and ultimately result in neurodegeneration and dementia. In the present study, we aim to

test the possibility that polymicrobial infections exist in post-mortem brain tissue samples from patients with Alzheimer's disease using overlapping molecular methods. To establish a link between neurocognitive disorders and microbial or polymicrobial infections, autopsy samples will be examined with immunohistochemistry, highly sensitive polymerase chain reaction, and RNA in situ hybridization. The aforementioned methods were used to successfully detect Borrelia burgdorferi, Bartonella henselae, Treponema denticola, and Candida albicans in neural tissue. These findings further indicate that microbes should be considered in the etiology of neurocognitive disease. Though the etiopathogenesis of Alzheimer's disease remains controversial, this study seeks to better elucidate the multifactorial neuropathology associated with dementia-inducing disorders as well as provide compelling evidence for the existence of persistent infection in brain tissue.

5241

EXAMINING THE ROLE OF NYMPHAL IXODES IN THE TRANSMISSION OF BORRELIA BURGDORFERI TO DOGS

Amy Schwartz, Angela Toepp, Kurayi Mahachi, Christine Petersen
University of Iowa, Iowa City, IA, United States

In the United States, Lyme disease (LD) is the most commonly reported vector-borne disease among humans. LD is caused by Borrelia burgdorferi which is transmitted to mammals through the bite of infected Ixodes ticks. Nymphal Ixodes, which quest in late spring and early summer, are responsible for the majority of transmission to humans; adult ticks are responsible for a subtler peak of cases in the fall. B. burgdorferi seroprevalence among dogs has been used to estimate LD risk among humans; however, past research has suggested that dogs are less susceptible to infection from nymphal Ixodes, possibly indicating a different host preference between dogs and humans for these different life stages. To evaluate this, we reviewed LD serology results from serially tested dogs over a 9-month period to better understand timing of seroconversion and frequency of transmission by Ixodes nymphs versus adults ticks to canine hosts. In 2016, blood was collected from 215 dogs at 3 timepoints (February, August, and November). In February, blood was tested by SNAP 4Dx Plus Test and Borrelia burgdorferi C6 ELISA. Testing was limited to C6 ELISA for later timepoints. Dogs were considered serologically positive for LD if they were positive by SNAP 4Dx Plus Test or Borrelia burgdorferi C6 ELISA. Of 161 dogs serologically negative for B. burgdorferi in February, 4 seroconverted by August. All 4 dogs resided in the East region. Of 146 dogs that were serologically negative in August, 15 seroconverted by November; dogs resided in the East (10), Mid-west (3), South (1) and West (1) regions. Although the majority of canine incident cases as indicated via seroconversion occurred during adult tick season, results indicate that four dogs became infected prior to adult tick season. Future studies may be warranted to better understand the role of nymphal Ixodes ticks and B. burgdorferi transmission in dogs. Nymphal transmission of B. burgdorferi to dogs has important implications for dog-owners, veterinarians and researchers studying LD among dogs, especially in circumstances where dogs are used as proxies for human risk.

MULTI-DRUG THERAPY IS REQUIRED TO EFFECTIVELY TREAT BARTONELLA INFECTION IN DIFFERENT ENVIRONMENTS

Emily Olsen, Monica Embers
Tulane National Primate Research Center, Covington, LA, United States

Bartonella is a gram negative, facultative intracellular bacterium that manifests as different clinical syndromes collectively known as bartonellosis. The well-known diseases caused by these bacteria are cat scratch disease (B. henselae), trench fever (B. quintana) and Carrion's disease (B. bacilliformis). Excluding B. bacilliformis, which is evolutionarily more distinct than the 30+ other species, Bartonella infections result in self-limiting disease that is often undiagnosed and untreated. However, individuals with compromised immune systems may experience clinical manifestations, which can become life threatening and need to be treated with effective antibiotics. To date, there is no standard treatment course for these infections and many doctors prescribe antibiotics based on limited case studies. It has been shown that Bartonella can grow extracellularly, intracellularly, and in biofilms. To determine an effective antibiotic strategy, it is important to understand Bartonella susceptibility in each of these growth conditions. We hypothesize that combination antibiotic treatments are required to effectively eliminate B. quintana and B. henselae growth, particularly in biofilm and intracellular environments. In previous studies, B. henselae treatment with single antibiotics in different media, as well as in DH82 canine macrophages, was ineffective in preventing growth. We plan to expand this work with different antibiotics supported by case reports, as well as double and triple combination therapy in erythrocytes and biofilms. Antibiotics tested were the following: doxycycline, gentamicin, azithromycin, azlocillin, rifampin, and clarithromycin. The effectiveness of combination therapy supports the notion that Bartonella species utilize target cells and biofilms as an antibiotic evasion strategy in the treatment of bartonellosis.

DIVERSITY AND DNA BARCODING OF IXODIDAE AND ARGASIDAE TICKS IN THE US-MEXICO BORDER REGION OF THE MUNICIPALITY OF JUAREZ, CHIHUAHUA

Javier A. Garza-Hernandez[1], Stephanie V. Laredo-Tiscareño[1], Jaime R. Adame-Gallegos[2], Carlos A. Rodríguez-Alarcón[1], Ezequiel Rubio-Tabarez[1], Erick de Jesús De Luna-Santillana[3], Diana M. Beristain-Ruíz[1], Alejandro Martínez-Martínez[1], Alejandra Rivera-Martínez[1], Elisa Díaz-Trejo[1], Angela N. Polanco-Leyva[1], Angela G. Sanchez-Rosales[1], Angel R. Ceballos-Chavéz[4], Rodolfo González-Peña[5], Luis M. Hernández-Triana[6]
[1]Universidad Autonoma de Ciudad Juárez, Ciudad Juarez, Mexico, [2]Universidad Autonoma de Chihuahua, Ciudad Juarez, Mexico, [3]Instituto Politécnico Nacional, Reynosa, Mexico, [4]Universidad Tecnólogica de la Tarahumara, Guachochi, Mexico, [5]Universidad Autonoma de Yucatán, Ciudad Juarez, Mexico, [6]Animal and Plant Health Agency, Addlestone, United Kingdom

Ticks are the most important arachnids for human and animal health because they are vectors of a plethora of disease-causal agents, including bacteria and arboviruses. In the border municipality of Juarez, Chihuahua, severe cases of human rickettsiosis and a high prevalence of bacteria transmitted by ticks in domestic animals have been reported in recent years. Inadequate morphological identification due to similarity between morphospecies or identification of juvenile stages is a common problem of the prevention and control programs. As a result, DNA barcode technology is a reliable support tool for completing the morphological identification of ticks at the border between Mexico and the United States. This study reports the diversity and DNA barcode of Ixodidae (hard) and Argasidae (soft) ticks collected between 2018-2022 along this Mexican border municipality. Based on morphology and confirmed species identity using DNA barcoding, 3245 ticks belonging to four species were collected along Juarez municipality in Chihuahua, state. Ticks were identified as Rhipicephalus sanguineus, Dermacentor albipictus, Otobius megnini, and Argas persicus. A Bayesian analysis was constructed with a sample of 65 Cytochrome Oxidase subunit I mitochondrial sequences of the ticks collected. The topology of Bayesian tree displayed tree groups of R. sanguineus, whereas the clades of other species were well-defined. The Markov model of nucleotide substitution for distance estimation show a mean (±SE) of 18 (±1.0) %. The intraspecific distance ranged between 0 to 0.02 %, whereas the interspecific distance was reached 11.9 to 29.5 %. Dogs were the major host of Rh. sanguineus, whereas O. megnini were predominant mostly on cows and horses. A. persicus were collected on soil, and D. albipictus were collected only on one deer. Finally, the public health importance of these species from the perspective of the public health of transboundary United States-Mexico region is also discussed.

5244

KNOWLEDGE, ATTITUDES, AND PRACTICES OF PARA-VETS ABOUT TICKS AND TICK-BORNE DISEASES IN PAKISTAN

Abrar Hussain, Dr. Rebecca Lee Smith

Department of Pathobiology, College of Veterinary Medicine, University of Illinois Urbana Champaign, Urbana, IL, United States

Recent global changes have accelerated the spread of ticks and tick-borne diseases, affecting animals and humans. According to a livestock survey in Pakistan, there are 41.2 million buffaloes, 49.6 million cattle, 78.2 million goats, and 30.9 million sheep. Among this massive population of ruminants, a tick infestation prevalence of 34.83% (buffalo), 57.11% (cattle), 51.97% (sheep), and 46.94% (goats) has been reported. Most livestock farmers rely on para-veterinary workers (whose training level resembles veterinary technicians in the US but can vary in quality and depth) for assistance with any animal health problem. However, little is known about the knowledge and practices of these para-veterinary workers regarding tick control and management. The objective of this study is to fill this gap using an epidemiological survey that can evaluate their knowledge and practices regarding tick-borne diseases in different regions of Pakistan. We designed a web-based knowledge, attitudes, and practices survey about ticks and tick-borne diseases. We will disseminate the questionnaire between March 2023 and June 2023 among para-veterinary workers of Pakistan to assess their awareness and response toward tick-borne disease management in animals. We will then analyze the survey to identify areas of low knowledge or ineffective practice in smallholder livestock settings. The survey has been designed and approved for dissemination, but most recruitment will be centered in May. We will use the results of this survey to design outreach and education materials for para-veterinary workers to improve their understanding and practices for managing and controlling tick-borne diseases.

5245

BODY LICE PATHOGEN SURVEILLANCE AMONG INDIVIDUALS EXPERIENCING HOMELESSNESS IN WINNIPEG, CANADA 2020-2021

Carl Boodman[1], Robbin L. Lindsay[2], Antonia Dibernardo[2], Kathy Kisil[3], Amila Heendeniya[4], John Schellenberg[4], Yoav Keynan[4]

[1]University of Manitoba (Canada)/ Institute of Tropical Medicine (Belgium), Antwerp, Belgium, [2]Public Health Agency of Canada, Winnipeg, MB, Canada, [3]Winnipeg Regional Health Authority, Winnipeg, MB, Canada, [4]University of Manitoba (Canada), Winnipeg, MB, Canada

In 2020, Canada's largest cluster of Bartonella quintana endocarditis was described among individuals experiencing homelessness in Winnipeg, Canada. The aim of this study was to analyze ectoparasites collected from individuals experiencing homelessness in Winnipeg to confirm vector species and identify B. quintana and other pathogens. This study, Canada's first on body lice, correlates B. quintana gene cycle threshold (Ct) with louse instar and sex. Ectoparasites were collected among consenting adults seeking medical care in Winnipeg. Ectoparasites were collected from discarded infested clothing and separated into pools based on instar and sex. Ectoparasite pools were decontaminated and homogenized. DNA was extracted. Vector species, louse ecotype and pathogens were identified using real-time PCR. Louse species and ecotype were identified using the louse mitochondrial cytochrome b (cytB) and Phum_PHUM540560 genes, respectively. Pathogens were identified using the following targets: ITS3 (B. genus), yopP and fabB (B. quintana), ompB (Rickettsia prowazekii) and IS1111a (Coxiella burnetii). 7 individuals submitted ectoparasites. All ectoparasites were confirmed to be Pediculus humanus corporis using real-time PCR. Lice from one individual (14%) demonstrated B. quintana positivity: ITS3, yopP and fabB. Lice from all individuals were negative for R. prowazekii and C. burnetii. Average B. quintana Ct (combined average of ITS3, YopP and FabB) decreased from 1st and 2nd instar pools to 3rd instar pools by 6.5. Average B. quintana Ct decreased from 3rd instar pools to 4th instar pools by 1.2. Pools from female adult louse pools demonstrated lower Ct values than male pools. A minority of body lice collected from individuals experiencing homelessness in Winnipeg demonstrated molecular positivity for B. quintana. Body lice in Winnipeg do not appear be significant vectors for R. prowazekii or C. burnettii. Ct on B. quintana genes decreases with each advancing instar. Manitoban individuals with pediculosis should be evaluated for B. quintana infection.

5246

TICK AND TICK-BORNE DISEASE KNOWLEDGE ACROSS FRONTLINE GROUPS: A KNOWLEDGE, ATTITUDES, AND PRACTICES META-COMPARISON

Rebecca L. Smith

University of Illinois Urbana-Champaign, Urbana, IL, United States

Prevention of tick bites and tick-borne diseases (TBDs) is reliant on individual-level protection measures, such as use of repellants and frequent tick checks in high-risk areas. However, these require knowledge of local spatiotemporal risk, awareness of basic prevention measures, and concern sufficient to implement protection measures. Since 2018, we have conducted Knowledge, Attitudes, and Practices surveys within multiple populations for which ticks and TBDs are a concern in the state of Illinois, USA. These populations include employees of local public health departments (n=42), veterinary professionals (n=72), and medical professionals (n=346). We will compare knowledge scores, subscores and TBD concern levels among these different populations, and compare their responses to existing tick presence and abundance and TBD prevalence data at the county and regional level. For instance, medical professionals had a higher median tick knowledge score (69%) than veterinarians (59%) or public health officials (52%), but veterinarians had a higher median disease score (47%) than the other two groups (30%). These scores varied significantly by time since last training for both veterinarians and medical professionals. These findings can serve as the basis of a One Health approach to tick prevention outreach and training for those at the front lines of TBD prevention.

IDENTIFICATION OF PULEX IRRITANS VERTEBRATE HOSTS IN PLAGUE-ENDEMIC AREAS OF MADAGASCAR USING MULTIPLEX POLYMERASE CHAIN REACTION

Annick O. Raveloson[1], Nick An[2], Stephen G. Mugel[2], Andry Andriamiadanarivo[3], Romain Girod[1], Thomas R. Gillespie[2], Adélaïde Miarinjara[2]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Emory University, Atlanta, GA, United States, [3]Centre ValBio Ranomafana, Ranomafana, Madagascar

Plague is a zoonotic disease, transmitted to humans by flea bites infected with the Yersinia pestis bacterium. The plague transmission cycle is complex and can involve several mammal hosts with various susceptibilities to the disease, including humans. Fleas acquire the infection while feeding on the septicemic host and transmit it upon the next feeding. Thus, host specificity and preference determine the flea's role in pathogen transmission, for the host blood can affect the flea's ability to transmit Y. pestis. Pulex irritans, the "human flea," is one of the probable vectors in Madagascar where plague is endemic. Previous investigations demonstrated that P. irritans is the most abundant species in households and it has been found infected with Y. pestis during epidemics. Identifying P. irritans host blood source will give a new insight into better understanding the plague transmission cycle in Madagascar. Here we report the preliminary results from a study aiming to identify the host blood source of P. irritans collected from households in a plague-endemic area of Madagascar. The DNA of individual blood-engorged P. irritans was extracted and amplified using conventional multiplex PCR, with a primer set that can amplify DNA from humans, birds, and non-human mammals DNA. The amplified DNA was visualized using gel electrophoresis to identify which P. irritans samples were positive for the three types of hosts. Our results showed that from 376 individual P. irritans, 79.25% fed on human hosts, 6% fed on avian hosts, and 1% fed on

non-human mammal hosts. All avian DNA-positive samples were positive with human DNA, and all non-human mammal-positive samples were positive with human and avian DNA. We could not detect host DNA from the remaining 20.75% of the fleas. We demonstrated that although this flea species is mostly anthropophilic, it can also feed on other hosts such as birds and mammals in Madagascar. Our finding raises concern about plague transmission, especially if P. irritans would take a blood meal from rodents, the main reservoir of plague in Madagascar. Our next step will be to identify the species involved for each non-human host.

5248

SPATIAL DISTRIBUTION AND MOLECULAR DETECTION OF RICKETTSIA SPP. IN RAT FLEAS IN MADAGASCAR

Soanandrasana Rahelinirina[1], Rado Jean Luc Rakotonanahary[1], Marcela Espinaze[2], Sandra Telfer[2], Minoarisoa Rajerison[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]University of Aberdeen, Aberdeen, United Kingdom

Rickettsioses are infectious diseases caused by bacteria of the genus Rickettsia and are mainly transmitted by arthropod vectors. Most of them are transmitted by ticks but R. typhi (murine typhus) and R. felis (flea-borne spotted fever) are transmitted by fleas and can cause severe illness and death. The aim of this study was to detect Rickettsia spp. from the fleas infesting small mammals in areas with different bioclimatic in Madagascar. The study was conducted in 28 districts across Madagascar. Urban and rural areas are randomly chosen for each district and small mammal traps were set across different habitats including house, vegetation, field, market and abattoir. Fleas were collected from small mammals and identified. The presence of Rickettsia spp. was assessed by qPCR specific for R. typhi and R. felis. A total of 3694 fleas belonging to Xenopsylla cheopis (97.0%) and an endemic flea Synopsyllus fonquerniei (3.0%) were collected from 2046 small mammals captured from 56 localities. Rattus rattus represented 71.3% of the total animals captured and R. norvegicus had high flea infestation of X. cheopis (61.2%). In this study, 1323 oriental fleas X. cheopis and 100 endemic fleas S. fonquerniei were randomly tested. Rickettsia spp. was identified in 16,4% of X. cheopis (217/1323) and 5% of S. fonquerniei (5/100). For Rickettsia species, 5.6% and 3.9% of X. cheopis were positive for R. typhi and R. felis respectively. For the endemic flea S. fonquerniei, 4% were positif for R. felis and none for R. typhi. Coinfection was found in 2 small mammals. Sixteen districts of the 28 were found infested with Rickettsia spp.. Infected fleas were found in all habitats mainly inside houses and in market place and the prevalence was higher in urban areas. Although no clinical case has been described in Madagascar, R. typhi was detected in naturally infected fleas from rats in Madagascar. The geographic distribution of the pathogen emphasizes the potential risk of flea-transmitted infections and the risk is high when animal carries many fleas. Investigations are needed to further understand the ecology of Rickettsia in fleas and their implications for human health.

5249

STATUS EPILEPTICUS AND MULTIORGAN INJURY IN A PATIENT WITH MURINE TYPHUS

Camille Spears, Divya Chandramohan, Gregory Anstead, James Saca

UTHSCSA, San Antonio, TX, United States

A 40 year old man with a history of epilepsy, well controlled on valproic acid for over a decade, presented with 2 weeks of fevers, headaches, and cough. Initial lab results showed leukocytosis, thrombocytopenia, and elevated transaminase, alkaline phosphatase, and creatinine levels. The patient developed generalized tonic-clonic seizures in the emergency room that progressed to status epilepticus, necessitating intubation and mechanical ventilation. A lumbar puncture (LP) was performed, showing an elevated opening pressure, a decreased cerebrospinal fluid (CSF) glucose level, elevated CSF protein, and an elevated CSF pleocytosis with neutrophil predominance. CSF cytologic exam showed plasma cells and plasmacytoid lymphocytes. MRI brain and CT chest returned unremarkable. CT abdomen showed hepatosplenomegaly and wall thickening of the distal ileum and ascending colon. The patient initially received vancomycin, ceftriaxone, doxycycline, acyclovir, and antiepileptic drugs. Rickettsia typhi IgM and IgG titers both returned elevated at 1:1024. Therapy was narrowed to doxycycline, and fevers and seizures resolved. A repeat LP showed improved opening pressure and cell counts, and after extubation, the patient was alert and oriented with a persistent headache but no focal neurologic deficits. He reported two dogs and one cat at home (not on flea prevention). He also had traveled to Panama and Colombia 4 weeks prior to symptom onset and spent time outdoors without insect repellant. Flea-borne typhus (FBT), caused by Rickettsia typhi, can often cause a headache as a primary symptom but encephalitis and status epilepticus are rare presentations. Our patient, fortunately, made a full recovery, but the complications of FBT encephalitis can be devastating, with one study showing mortality or neurologic sequelae at 27%. Case numbers of FBT and geographic ranges in Texas and California are expanding, so it is increasingly urgent to study rare presentations of this infection and recognize them promptly to reduce morbidity and mortality.

5250

MOLECULAR DETECTION, CYTOLOGICAL CHARACTERIZATION, AND GENETIC HETEROGENEITY OF 16S RDNA OF HEMOTROPIC MYCOPLASMAS IN POPULATIONS OF SMALL MAMMALS IN TWO STATES OF BRAZIL

Maristela Peckle Peixoto[1], Eduarda de Oliveira Machado[1], Bernardo Rodrigues Teixeira[2], Tatiana Padua de Freitas[2], Lais da Silva de Oliveira[1], Huarrisson Azevedo Santos[1], Carlos Luiz Massard[1]

[1]Federal Rural University of Rio de Janeiro, Seropedica, Rio de Janeiro, Brazil, [2]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Hemotropic mycoplasmas are pleomorphic, non-cultivable bacteria attached to the red blood cell surface. They have been detected in human patients with immunodeficiency conditions or co-infected with other infectious agents. New species and genotypes have been described in wild animals. This study aimed to perform molecular detection, cytological characterization, and genetic heterogeneity of 16S rDNA of hemotropic mycoplasmas in small mammals from Rio de Janeiro and Parana, Brazil. A total of 258 small mammals were captured. The cytological analysis was performed using a blood smear stained with Giemsa solution. Molecular detection of agents from the Family Mycoplasmataceae was based on the 16S rRNA gene. The products amplified in the polymerase chain reaction (PCR) were selected and purified for subsequent sequencing and construction of the phylogenetic tree. There were 11 Mycoplasma spp. of small wild mammals from this study. They were joined to another 32 sequences, with Mycoplasmoides fastidiosum as an outgroup, in a dataset of 1050 positions. Among the 258 samples of small wild mammals analyzed, 23.2% (n=60) presented structures compatible with Mycoplasma sp. in erythrocytes. 33.7% (n=87) samples amplified Mycoplasma sp. in conventional PCR. The region with the highest frequency of positivity was Cruz Machado (46.15%, n = 24/52), followed by Ponta Grossa (43.10%, n=25/58), Nova Friburgo (30.56%, n= 33/108), and Lidianopolis (12.50%, n=5/40). Oligoryzomys had the highest percentage of positivity (78.05%), statistically differing from Oxymycterus spp. (42.11%), Akodon spp. (27.59%) and Sooretamys (9.09%). Males were more frequently parasitized with Mycoplasma spp. than females ($p<0.001$). Regarding the phylogenetic analysis, Mycoplasma spp. from this study grouped together with Oligoryzomys nigripes from São Paulo and Minas Gerais, forming a clade with these sequences. This study revealed the morphological, eco-epidemiological, and phylogenetic aspects of Mycoplasma spp. in small non-flying wild mammals in regions of the states of Parana and Rio de Janeiro, Brazil.

5251

VIRAL AND BACTERIAL SEQUENCING OF FEBRILE PATIENT PLASMA REVEALS HIGH PREVALENCE OF TICK-BORNE BACTERIAL PATHOGENS IN THIÈS, SENEGAL

Zoe Levine[1], Aita Sene[2], Mouhamad Sy[2], Awa Deme[3], Amy Gaye[2], Tolla Ndiaye[2], Pardis Sabeti[1], Katherine Siddle[4], Daouda Ndiaye[2]

[1]Broad Institute, Cambridge, MA, United States, [2]CIGASS, Dakar, Senegal, [3]CIAGSS, Dakar, Senegal, [4]Brown University, Providence, RI, United States

While the incidence of malaria infection in Senegal has decreased rapidly in recent years, febrile disease continues to be a major cause of morbidity and mortality. In order to better understand causes of non-malarial febrile illness (NMFI) in Thiès, Senegal, we collected plasma samples and clinical metadata from febrile patients (n = 563) and healthy controls (n = 500) across both dry and rainy seasons from 2018-2019. We optimized amplicon sequencing of the 16S rRNA V1-2 region to screen for bacterial pathogens and unbiased RNA sequencing to screen for viral pathogens. Unbiased RNA sequencing detected Dengue virus, Hepatitis B virus, and Parvovirus B 19 infections in our cohort. 16S sequencing revealed a high prevalence of Borrelia spp. and Rickettsia spp. in febrile patients, but not in controls. As compared to qPCR, 16S sequencing was sensitive and specific for detection of bacterial infections. Patients infected with Borrelia spp. experienced a range of symptoms, many of which overlapped with common symptoms of malaria, and had a unique immune response, characterized by decreased lymphocyte count and increased granulocyte count. These data demonstrate that 16S sequencing is a useful tool for detecting bacterial pathogens across a large number of plasma samples and could be employed for future surveillance. Further, the results indicate that arthropod-borne bacterial pathogens are a significant contributor to NMFI in Senegal, suggesting the need for improved diagnostics, increased access to treatment, and vector control efforts in the region.

5252

SPOTLIGHT REPORT: HISTORIC TICK SURVEILLANCE OF SIERRA LEONE

Graham Matulis[1], Abigail Lilak[1], David B. Pecor[2], Alexander M. Potter[2], Dustin Rodriguez[3], Regina M. Jobson[1], Michael E. von Fricken[1], Yvonne-Marie Linton[2]

[1]George Mason University, College of Public Health, Fairfax, VA, United States, [2]Walter Reed Biosystematics Unit (WRBU), Smithsonian Institution Museum Support Center, Suitland, MD, United States, [3]James Madison University, Harrisonburg, VA, United States

Using a systematic review, the goal of this study was to better characterize the distribution of ticks and the microbial species they carry within Sierra Leone. Nineteen search terms, and their corresponding MeSH terms, were used to compile scientific literature from the PubMed, Scopus, and WOS search engines published between 1901–2022, resulting in an initial capture of 109 articles. These results were screened for relevance according to title and abstract, after which only six articles met the final inclusion criteria. Two additional articles were captured from searches of the reference sections of included articles as well as from the search results of another West African country, for a total of eight articles selected for data extraction. Information captured during the data extraction process included tick species, collection locality, collection host, and pathogen detections. A total of seven genera of ticks were reported from the articles, including Amblyomma (5 species/subspecies), Dermacentor (1), Haemaphysalis (4), Hyalomma (1), Ixodes (2), Ornithodoros (1), and Rhipicephalus (9). Most ticks were collected feeding on host animals, of which 66.2% (51/77) were collected from domestic animals. Wildlife hosts included African buffalo, ball pythons, bush elephants, chimpanzee, duikers, pangolins, and mongoose. Of note, no pathogen testing was conducted in any of the ticks collected in these studies. These results identify major gaps in tick surveillance information within Sierra Leone, with much more tick surveying needed from the environment and wildlife. Findings from this study emphasize the need for future studies to assess the prevalence of tick-borne pathogens within the tick populations of Sierra Leone.

5253

SARS-CO-V2 INFECTION AND RISK FACTORS AMONG HEALTH WORKERS IN BAMAKO, MALI: A LONGITUDINAL STUDY

Drissa Konate[1], Saidou Balam[1], Amadou Kone[1], Bourama Traore[1], Housseini Dolo[1], Dramane Diallo[1], Abdouramane Traore[1], Salimata Kante[1], Mariam Sidibe[1], Bourama Keita[1], Aminatou Coulibaly[1], Fatoumata Kasse[1], Karamoko Tangara[1], Issoufi Y Maiga[1], Merepen dite Agnes Guindo[1], Mama Sy Konake[2], Marietou Traore[2], Abdoul RA Dicko[2], Naman Keita[2], Ousmane Diamoutene[2], Diakaridia Kone[2], Yaya Ibrahim Coulibaly[3], Ousmane Faye[3], Mahamadou Diakite[1], Seydou Doumbia[1]

[1]USTTB, Bamako, Mali, [2]MoH, Bamako, Mali, [3]Dermatology hospital of Bamako, Bamako, Mali

Health workers (HW) on the front lines of the COVID-19 pandemic control are at high risk of SARS-Co-V2 infection and could contribute to its spread at the community level. This study aimed to estimate the prevalence of SARS-Co-V2 infection and associated factors among HWs to strengthen the prevention measures. A longitudinal study was conducted from November 2021 to February 2023 in six health districts and two university hospitals of Bamako, the capital city of Mali and epicenter of the pandemic. Sociodemographic characteristics, clinical data and nasopharyngeal swabs were collected during four rounds. RT-PCR was used to determine SARS CoV 2 infection. Mixed-effects Cox regression models were used to estimate the risk of SARS CoV 2 infection with a threshold at 5%. A total of 1098 participants were enrolled with 63.5% female and 36.5% male. The nurses (34.7%) and administrative staff (20.5%) were common. Over the study period, 9.8% of participants declared to have had a contact with COVID 19 patients and 20.7% with the COVID-19 samples. The prevalence of SARS-Co-V2 infection was 3.4%, 0%, 1.3% and 5.1% in Round 1, Round 2, Round 3 and Round 4, respectively. Chronic diseases (AOR=2.08, 95%CI [1.20 3.61]), contacts with COVID-19 samples (AOR=1.72, 95%CI [1.10 2.68]) or with COVID 19 patients (AOR=2,95%CI [1.16 3.44]), and participation to indoor events with more than 10 people (AOR=1.66, 95%CI [1.02 2.70]), were associated with higher risk to develop COVID 19 symptoms. COVID-19 vaccines seem to reduce confirmed cases, but the change was not statistically significant (AOR=0.68, 95%CI [0.28 1.68]). In conclusion, the study showed a high prevalence of SARS CoV 2 infection during Rounds 1 (at inclusion) and 4 and identified some factors associated to COVID 19. No protective effect of COVID-19 vaccines was observed. Further studies are needed to assess the effectiveness of COVID 19 vaccines and how to strengthen COVID 19 prevention measures in Mali.

5254

IMMUNE CROSSED REACTIVITY BETWEEN SARS-CO-V2 AND PLASMODIUM FALCIPARUM ANTIGENS IN SERA FROM COVID-19 PATIENTS AND PRE-COVID-19 DONORS IN MALI WEST AFRICA

Abdouramane Traore[1], Saidou Balam[1], Drissa Konate[1], Bourama Traore[1], Merepen Agnès Guindo[1], Karamoko Tangara[1], Salimata Kante[1], Issoufi Maiga[1], Seidina Aboubacar Samba Diakite[1], Fatoumata Kasse[1], Yaya Ibrahim Coulibaly[2], Ousmane Faye[2], Giampietro Corradin[3], Mahamadou Diakite[1]

[1]USTTB, Bamako, Mali, [2]DHB, Bamako, Mali, [3]UNIL, Lausanne, Switzerland

While Western countries suffered severely of the COVID-19 pandemic, Sub-Saharan Africa countries registered low cases of the disease. In malaria endemic areas, cross-immunity betweenSARS-CoV-2 and Plasmodium is thought to exist. In 2022, we reported a significant cross-reactionof three SARS-CoV-2 proteins to pre-COVID-19 sera (asymptomatic malaria) including Spike(21.9%), RBD (6.7%), and peptide RBM (8.8%) proteins. Here, we have determined the cross-reactivity between the three SARS-CoV-2 proteins (Spike, RBD, RBM) and P. falciparum bloodstages antigens (Pf27 and LR253) in sera from COVID-19 patients and pre-COVID-19 volunteersin Mali. COVID-19 samples were collected in 2020 amongst

COVID-19 patients (n = 188) at the Dermatology Hospital of Bamako. Pre-COVID-19 sera from Nioro du Sahel (clinical malariacases, n = 51) and Dangassa (asymptomatic and healthy donors, n = 157), were collected in 2013and 2018, respectively, before the onset of COVID-19 in Mali. Samples were tested using ELISAassay to assess IgG antibodies level against each antigen. Overall, seroprevalence was higher inclinical malaria samples compared to COVID-19 samples for Spike (65.9% vs 53.19%, p = 0.01),RBD (61.1% vs 23.9%, p = 0.001), RBM (29.1% vs 37.5%, p = 0.08), LR253 (71.1% vs 32.4, p =0.001), and Pf27 (38.5% vs 28.2, p = 0.03). A significant low correlation was found betweenantibodies anti-P27 and anti-Spike (r = 0.27, p = 0.002), anti-P27 and ant-RBD (r = 0.34, p =0.001), anti-P27 and RBM (r = 0.26, p = 0.001) in pre-COVID-19 samples. The highseroprevalence of antibodies against SARS-CoV-2 proteins in malaria endemic areas may suggestcross-reactivity with malaria parasite and further investigation is needed to better understand therole of Plasmodium in COVID-19 spreading in these areas.

DEVELOPMENT OF A DIAGNOSTIC IGM-ANTIBODY CAPTURE ELISA FOR DETECTION OF ANTI-CACHE VALLEY VIRUS HUMAN IGM

Amanda E. Calvert[1], Sierra R. Mikula[1], Jordan R. Powers[1], Holly R. Hughes[1], Brad J. Biggerstaff[1], Kelly Fitzpatrick[1], Amanda J. Panella[1], Carlos Machain-Williams[2], SeungHwan Lee[3], Christin Goodman[1]

[1]U.S. Centers for Disease Control and Prevention, Fort Collins, CO, United States, [2]Laboratory of Arbovirology, Regional Research Center "Dr. Hideyo Noguchi" Universidad Autónoma de Yucatán, Merida, Mexico, [3]Seoul National University, Seoul, Korea, Republic of

Cache Valley virus (CVV) is a mosquito-borne virus in the genus Orthobunyavirus, family Peribunyaviridae that has been identified as a teratogen in ruminants causing fetal death and severe malformations during epizootics in the United States. CVV has recently emerged as a potential viral pathogen causing severe disease in humans. Limited information exists on its potential as a human teratogen. The only serological diagnostic assay available to detect recent CVV infections is the plaque reduction neutralization test (PRNT) which requires the use of live virus in biosafety level 2 (BSL-2) biocontainment. In order to expand human serological diagnostic capacity for CVV we have developed an immunoglobulin M (IgM)-antibody capture enzyme-linked immunosorbent assay (MAC-ELISA) for detection of anti-CVV human IgM in diagnostic specimens. In conjunction, a HEK-293 cell line constitutively expressing a human-murine chimeric antibody with the variable regions of murine monoclonal antibody (MAb) CVV17 and the constant regions of the human IgM was developed to overcome the lack of human positive sera used as controls in the assay. The new cell line produced antibody with higher reactivity (≥3-fold) in the assay compared to a human serum sample positive for anti-CVV IgM. Previously collected human diagnostic specimens from the United States and Mexico from patients with acute febrile illness with no known etiologic agent will be tested in MAC-ELISA and PRNT to determine the utility of the assay in CVV-serodiagnostics. These results will be summarized and discussed.

USING REGIONAL SERO-EPIDEMIOLOGY SARS-COV-2 ANTI-S ANTIBODIES IN THE DOMINICAN REPUBLIC TO INFORM TARGETED PUBLIC HEALTH RESPONSE

Beatris Mario Martin[1], Angela Cadavid[1], Helen Mayfield[1], Cecilia Then Paulino[2], Micheal de St. Aubin[3], William Duke[4], Petr Jarolim[3], Emily Zielinski Gutiérrez[5], Ronald Skewes Ramm[2], Devan Dumas[3], Salome Garnier[3], Maria Carolina Etienne[3], Farah Peña[2], Gabriela Abidalla[3], Lucia de la Cruz[2], Bernerda Henriquez[2], Margaret Baldwin[3], Adam Kucharski[6], Eric J. Nilles[3], Colleen L. Lau[1]

[1]The University of Queensland, Brisbane, Australia, [2]Ministry of Health and Social Assistance, Santo Domingo, Dominican Republic, [3]Brigham and Women's Hospital, Boston, MA, United States, [4]Pedro Henriquez Urena National University, Santo Domingo, Dominican Republic, [5]Centers for Disease Control and Prevention, Central America Regional Office, Guatemala City, Guatemala, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

Higher incidence of COVID-19 has been associated with sociodemographic factors such as living in an urban setting, high population density, and household crowding. In this study, we investigated variations in SARS-CoV-2 seroprevalence at regional and cluster levels in the Dominican Republic (DR) and assessed potential sociodemographic factors influencing the geographical distribution of COVID-19 at the regional level. Data were collected in a three-stage cross-sectional national serosurvey conducted in the DR from June to October 2021. Seroprevalence of antibodies against the SARS-CoV-2 spike protein (anti-S) was estimated and adjusted for selection probability, age, and sex. Multilevel logistic regression was used to estimate the effect of covariates on seropositivity for anti-S and correlates of 80% protection against symptomatic infection (PT80) for ancestral and Delta strains. A total of 6,683 participants from 134 clusters in all 10 administrative regions of the DR were enrolled in the survey. The adjusted anti-S prevalence ranged from 80.5% (95%CI 78.1-82.9) to 89.8% (95%CI 88.8-93.8) between regions, and from 25.7% (95%CI 24.3-27.1) to 100% (95%CI 91.2-100.0) between clusters. At the national level, Enriquillo and El Valle had the highest odds ratios (OR) for anti-S positivity (OR of 1.86 for both with 95%CI 1.24-2.80 and 1.14-3.10, respectively). Also, receiving three doses of COVID-19 vaccine was associated with anti-S positivity (OR of 121.56, 95%CI 16.85-876.60), PT80 for ancestral (OR of 15.76, 95%CI 10.12-24.26) and Delta strains (OR of 19.59, 95%CI 14.22-27.01). At the regional level, models identified that associations between covariates and outcomes varied between regions. However, vaccination was consistently associated with highest odds of seropositivity and correlates of protection in most regions. Our results can help inform more targeted regional-level public health response such as strategies to increase vaccination coverage in areas with low population immunity.

5257

DENGUE FEVER OUTBREAK AT THE KENYAN SOUTH COAST INVOLVING SEROTYPE 3, GENOTYPES III AND V

Eric Muthanje[1], Gathii Kimita[1], Josphat Nyataya[1], Beth Mutai[1], Sarah Kituyi[2], John Waitumbi[1]

[1]US-Army Medical Research Directorate-Africa, Kisumu, Kenya, [2]University of Embu, Embu, Kenya

Dengue fever (DF), caused by four distinct serotypes of dengue virus (DENV-1-4) is transmitted by the Aedes mosquito. There have been increasing reports of DF outbreaks in Africa, including Kenya, yet very little information is available on the virus, for instance diversity of circulating genotypes. The study aimed at characterizing DENV-3 strains from the March 2019 DF outbreak at the Kenyan south Coast. RNA was isolated from 37 human plasma samples and screened for the presence of DENV serotypes by RT-PCR. Only DENV-3 was identified. RNA from DENV-3 positive samples was used for cDNA synthesis using sequence-independent single-primer amplification (SISPA). Libraries were prepared using the NexteraXT kit, and sequenced on the Miseq. Quality filtering, sequence assembly and annotation was done using CLC Genomics v.8.5, while phylogenetic analysis was conducted in MEGA v10. A targeted sequencing approach for envelop gene was used on samples that failed to yield complete genomes. 21/37 samples tested positive for DENV-3. On sequencing, 4 samples produced complete genome (10,173 bp) and 3 had partial sequences with complete env genes (1479 bp). Partial sequences with incomplete env genes were generated from 14 samples which were re-sequenced by targeted amplification. This approach produced ten complete env genes (1439-1479 bp). Maximum likelihood analysis of the 4 complete genomes and the 17 env genes confirmed DENV-3 (GIII=15 and V=2) as the cause of the March 2019. The estimated time-to-most-common recent ancestor for the two genotypes was in 2015. Genotype III's origin was estimated to have been introduced from Pakistan. The origin of genotype V could not be ascertained due to rarity of these sequences globally, but was related to 2006 Brazilian isolate. Unlike genotype III that has been described in East and West Africa multiple times, this was the

second description of genotype V in Kenya. The generated data adds DENV-3 genome sequences to the GenBank, thus remedying the scarcity of African DENV sequences in public database. Lastly, the study will contribute to the understanding of the cyclical transmission of DENV at the Kenya coast.

5258

DEVELOPMENT OF A DNA HYBRIDIZATION PROBE-BASED SURVEILLANCE ASSAY FOR DETECTION OF ARBOVIRUSES IN ARTHROPOD POOLS

Marisa Foster, Linda Kothera, Emily Davis, Joanie Kenney
Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States

Vector-borne pathogens continue to burden public health, thus advanced detection and surveillance methods are needed. Sensitivity and specificity constraints have limited development of multi-pathogen detection assays. Metagenomic sequencing has been used for microbial detection, but often lacks sensitivity for detection of low-abundance nucleic acid species. Here we present Comprehensive Molecular Entomological Surveillance (CMES)-viral, a method for enhanced detection of nucleic acids through probe-based enrichment. DNA hybridization probes were designed to cover full genomes and account for genetic diversity of 24 arboviruses of concern in CONUS. We developed a method for next generation sequencing detection of low quantity viral nucleic acids from arthropod pools. We optimized library preparation protocols and probe panel design using spiked arthropod pools for each target virus and assessed sensitivity compared with qRT-PCR and plaque titration. Additional efforts focused on creation of a simplified and standardized pipeline using the free and publicly available genetic data analysis platform, Galaxy. CMES-viral demonstrated higher sensitivity than viral titration and could detect viral genetic diversity. This assay demonstrates the ability to use NGS as a method of surveillance to successfully detect multiple arboviruses within vector samples in a single run. This approach supports the goal of reducing the global burden of arboviruses by providing an additional tool for comprehensive surveillance of arboviral vectors.

5259

COLORIMETRIC RT-LAMP ASSAY FOR DETECTION OF LA CROSSE VIRUS IN ARTHROPOD POOLS

Joanie Kenney, Nathaniel Byers
Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States

La Crosse virus (LACV) is the leading cause of arboviral pediatric encephalitis and is likely underdiagnosed. Due to the nonspecific symptoms early diagnosis is lacking, as are available treatments. The virus is primarily transmitted by Aedes triseriatus; though invasive container inhabiting mosquitoes, Ae. japonicus and Ae. albopictus, are also recognized vectors. Due to focal circulation of this virus, surveillance in mosquitoes is not consistently performed across the geographic range of LACV. Technical expertise and funding required for qRT-PCR testing is often not available in locales where transmission foci exist. To bridge the gap between field personnel collecting vector mosquitoes and state health departments with the capacity for qRT-PCR testing, we developed a reverse transcription loop-mediated isothermal amplification assay (RT-LAMP) for detection of LACV using a colorimetric indicator. Five sets of four primers were designed to the LACV S segment utilizing the NEB® LAMP Primer Design Tool and initial analysis in silico indicated two of the five sets to be ideal candidates. Primer sets were assessed for sensitivity and specificity in comparison to qRT-PCR utilizing multiple LACV strains and other orthobunyavirids spiked into mosquito pools. In summary, we developed a sensitive colorimetric assay that requires minimal technical experience or advanced machinery and can be easily deployed in local settings for arthropod surveillance of LACV. By making surveillance more accessible, these transferable assays have the potential to improve early recognition of circulating LACV and improve human health outcomes.

5260

HIGH TRANSMISSION OF ENDEMIC HUMAN CORONAVIRUSES DURING THE COVID-19 PANDEMIC IN ADOLESCENTS IN CEBU, PHILIPPINES

Ogeneitsega Janet Joseph[1], Michelle Ylade[2], Jedas Veronica Daag[2], Rosemary Aogo[1], Maria Vinna Crisostomo[2], Kristal-An Agrupis[2], Patrick Mpingabo[1], Lakshamane Premkumar[3], Jacqueline Deen[2], Leah Katzelnick[1]
[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines-Manila, Manila, Philippines, [3]Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States

SARS-CoV-2, the causative agent of COVID-19, is a betacoronavirus closely related to human endemic coronaviruses (hCoVs) OC43 and HKU1 and more distantly related to alphacoronaviruses 229E and NL63. For other pandemic respiratory pathogens, the emergence of novel subtypes leads to the extinction of others; it is unknown whether the same phenomenon may occur for hCoVs. We evaluated if pre-pandemic hCoV immunity affected the risk of contracting SARS-CoV-2 and whether SARS-CoV-2 infection affected the transmission of hCoVs among adolescents in the Philippines participating in a longitudinal dengue cohort study. We tested a random set of 499 out of 2035 study participants for positivity to SARS-CoV-2 receptor binding domain (RBD) by enzyme-linked immunosorbent assay (ELISA) in 2021. From this group, we randomly selected n=120 SARS-CoV-2 RBD negative and positive individuals for further study. ELISAs were used to measure binding antibodies (optical densities, OD) to RBD and spike proteins for all four hCoVs and SARS-CoV-2 for samples collected before the COVID-19 pandemic and after the spread of COVID-19 but before vaccination. We observed 79 to 91% seropositivity to the four hCoVs before the pandemic. ELISA ODs increased with age for 229E and OC43, suggesting endemic circulation, while immunity was flat across ages for HKU1 and NL63. High alphacoronavirus immunity at baseline correlated with an increased probability of SARS-CoV-2 infection, possibly indicating greater exposure to coronaviruses in general. Antibodies increased significantly to the RBDs of OC43, NL63, and 229E and spikes of all four hCoVs in both SARS-CoV-2 negative and positive adolescents. Those aged 13-15 years old in 2021 had higher antibodies to RBD and spike of OC43, NL63, and 229E than children the same age in 2019, further indicating intense transmission. Overall, we observe a limited effect of the COVID-19 pandemic or SARS-CoV-2 infection on endemic hCoV transmission. This study provides insight into the co-circulation of hCoVs as SARS-CoV-2 becomes an endemic pathogen.

5261

IDENTIFICATION OF IMMUNODOMINANT B AND T-CELL EPITOPES OF KYASANUR FOREST DISEASE VIRUS AND THEIR EXPRESSION FOR DEVELOPING RAPID DIAGNOSTICS AND POTENT SUBUNIT VACCINE

Rajeshwara Achur[1], Sayad Hafeez[2], Kiran S.K[3], Thippeswamy N.B[2]
[1]Department of Biochemistry, Kuvempu University, Shivamogga, India, [2]Department of Microbiology, Kuvempu University, Shivamogga, India, [3]Department of Health and Family Welfare, Shivamogga, Karnataka, India

The Kyasanur Forest Disease (KFD), which is also known as 'Monkey Fever' is caused by KFD Virus (KFDV) that belongs to the family Flaviviridae. KFD is a highly neglected and emerging tropical disease endemic to Western Ghat region of Karnataka, India, which is fatal with a mortality rate of 2-10%. Recently, KFD has been alarmingly spreading from its epicenter to neighboring districts and states also. The current ELISA based KFD diagnosis involves the detection of antibody in the patient's blood which is relevant only after the development of antibody following the infection and is non-specific due to cross-reactivity with other flaviviruses. Further, currently available formalin-inactivated vaccine developed in the 1970s has now been found to be less effective leading to increased disease susceptibility and

severity. To address these, the present study was aimed at identification of specific B and T-cell epitopes of KFDV immunogenic marker antigens using diverse computational tools to develop precise diagnosis and a potent subunit vaccine. Here, we have chosen E, NS1 and NS5 proteins as markers of KFDV by taking into account of their differential and non-overlapping sequences with selected arboviruses. Based on the linear and nonlinear epitope prediction tools and distinct biophysical parameters, we have identified three potential linear and ten nonlinear B-cell epitopes. Soon after the infection, NS1 protein is secreted heavily into the blood and protein E is expressed on the host cell surface. These two proteins have been expressed in bacteria and the antibody has been produced successfully in rabbit. For developing vaccine, the molecular docking and molecular dynamics simulation analysis has identified six different TH-cell epitopes based on the distribution frequency of MHC-II haplotypes in the human population and one TC-cell epitope from NS5 protein that has maximum interaction with class-I MHC. By using all these data, we are developing a precise and rapid KFD diagnostic tool and a potent subunit vaccine.

5262

A COHORT-BASED PILOT STUDY OF DETECTION OF LASSA VIRUS INTO THE ODONTOGENIC FIBROUS TUMOR IN KINSHASA, DEMOCRATIC REPUBLIC OF CONGO

Marco de Feo[1], Frédéric T. Dilu[2], **Anguy M. Makaka**[3], Gracia M. Kashitu[3], Opiyo S. Odong[4], Chiara Castellani[5], Patrick I. Mpingabo[3], Steve M. Ahuka[3], Silvia Di Agostino[6]

[1]Saint Mary's Hospital Lacor, Gulu, Uganda, [2]Maxillo-facial surgery and stomatology Unit, Department of General surgery, Kinshasa University Hospital, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [3]Department of Medical Biology, Kinshasa University Hospital, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [4]Gulu Regional Referral Hospital, Gulu, Uganda, [5]School of Medicine, University of Bandundu, Bandundu, Congo, Democratic Republic of the, [6]Department of Health Sciences, Magna Græcia University of Catanzaro, Catanzaro, Italy

Lassa virus (LASV) belongs to the arenavirus genus and Arenaviridae family. It is highly pathogenic to humans, causing hemorrhagic fever. LASV has been reported to be endemic in several sub-Saharan countries where various tumors such as Odontogenic tumors (OTs) are also prevalent. A recent study has documented the presence of an arenavirus-like virus in human OT-like, odontogenic fibromyoma in a snake captive-bred red-tail boa (Boa constrictor). However, the association between OTs and LASV has not been established in humans yet. Here, we investigate the presence of LASV in tumor tissue samples from pilot cohort patients with OTs in Kinshasa. Tissue samples were collected from enrolled participants (n=29) and were tested for the detection of LASV using RT-qPCR. 83% (24/29) of analyzed tissue samples were LASV-positive. Furthermore, we found that not only the ameloblastoma was LASV positive, but also the bone close to the tumor and the oral mucosa lining the tumor This result is the first report of the presence of LASV in human OT tissues and highlights the potential contribution of LASV in the etiopathogenesis of human odontogenic tumors. Thus, deep molecular, immunological, and histological studies in the large cohorts are ongoing to characterize this cooccurrence of LASV and OTs.

5263

SEVERE FEVER WITH THROMBOCYTOPENIA SYNDROME VIRUS: AN UNDIAGNOSED EMERGING VIRAL INFECTION IN THAILAND

Pakpoom Phoompoung[1], Wilawan Thipmonthree[2], Julie Julie[3], Sonja Weiss[3], Michael G. Berg[3], Francisco Averhoff[3], Gavin A. Cloherty[3], **Yupin Suputtamongkol**[1]

[1]Siriraj Hospital, Bangkok, Thailand, [2]Maharat Nakhon Ratchasima Hospital, Nakhon Ratchasima, Thailand, [3]Abbott Laboratories, Chicago, IL, United States

Severe fever with thrombocytopenia syndrome virus (SFTSV) is an emerging tick-borne viral infection in China and other Asian countries. Due to its high fatality rate and its pandemic potential, SFTSV is listed among the top 10 priority infectious diseases requiring urgent research by the World Health Organization. Four cases of SFTSV were recently reported in Thailand. We performed unbiased metagenomic next generation sequencing (mNGS) coupled to viral target enrichment to identify known and novel viruses from 1,000 patients with undiagnosed, acute undifferentiated febrile illness (AUFI), hospitalized between 2014 and 2021 at Siriraj Hospital, Bangkok, Thailand. Three patients with SFTSV were detected, including a 61 -year female, 75 -year male and 77- year male with durations of illness of 7, 6 and 7 days, respectively. They presented with non-specific symptoms such as fever, myalgia, and their complete blood count (CBC) revealed marked leukopenia and thrombocytopenia. The initial diagnosis was dengue hemorrhagic fever in two individuals and sepsis with septic encephalopathy in the other who also presented with alteration of consciousness. Dengue NS1, IgM, IgG markers and antibodies against Rickettsia typhi and Orientia tsutsugamushi were not detected. All cases were treated with empirical ceftriaxone and azithromycin for 7 days. Two of them developed severe complications, including gastrointestinal bleeding, acute kidney injury and hospital acquired pneumonia. Their WBC count and platelets were normal prior to discharge. All cases of SFTSV (4 cases previously reported and 3 cases in this study) in Thailand were diagnosed between 2019 and 2020. We are conducting additional studies with AUFI specimens from as early as 2001 to determine if there has been an earlier introduction of SFTSV into Thailand. Our findings reinforce the need for rapid and accurate laboratory tests for the diagnosis of SFTVS in Thailand among febrile patients presenting with thrombocytopenia after dengue infection has been excluded.

5264

SPATIO TEMPORAL DYNAMICS OF MEASLES IN THE PROVINCE OF WESTERN KASAI IN DEMOCRATIC REPUBLIC OF CONGO FROM 2000 TO 2014

Divine Dilubenzi Suami, Didier Bompangue Nkoko, Rosine Bigirinama

URF/University of Kinshasa/INRB, Kinshasa, Congo, Democratic Republic of the

Despite immunization efforts since 2000, measles remains a major public health problem in the DRC. The upsurge of outbreaks throughout the country in general and in the province of the western Kasaï especially motivated the realization of this study.To start understanding of recurrence of these outbreaks.Measles cases and deaths reported in Kasai Occidental between 2000 and 2014 were used to calculate the attack rate and develop thematic maps for possible spatial heterogeneities. The outbreaks occurred during the period were analyzed together with an assessment of measles surveillance system.A total of 33,126 cases 3.82% deaths have been reported on all that ZS Luebo, Mweka and Benaleka were more at risk. Children less than 5 years unvaccinated 65.8% were more affected and no difference in sex.The identification of the epicenter formed of the 3 ZS opens a perspective to lead the studies to the scale of health areas in order to search for the factors explaining these heterogeneities.

5265

CLINICAL PRESENTATION AND LABORATORY ABNORMALITIES AMONG DENGUE SEROPOSITIVE AND SERONEGATIVE FEBRILE NIGERIAN ADULTS

Juliet Ijeoma Mmerem, Michael O. Iroezindu, Uche Unigwe, Chinedu Michael Chukwubike

University of Nigeria Teaching Hospital, Enugu, Nigeria

Dengue is a neglected tropical disease with outbreak potentials and a low index of suspicion. We compared the clinical and laboratory abnormalities between dengue seropositive and seronegative febrile adults at the Federal Medical Centre, Owerri, South-East Nigeria. This was a cross-sectional study of 90 febrile adults aged ≥18 years recruited consecutively between 1st February and 30th September 2020. Epidemiological, clinical, and laboratory data including dengue IgM and IgG antibodies (by ELISA), dengue non-structural protein 1 (NS1) antigen by two-step chromatography, complete blood count, liver enzymes, bilirubin, and prothrombin time were

obtained. Dengue seropositivity was defined as a positive IgM, IgG, or NS1. The mean age of the participants was 39.3 ± 16.4 and 48/90 (53.3%) were females. Dengue seropositivity was observed in 65⁄90 (72.2%) participants. The pattern of positivity for dengue markers comprised IgG only (38.9%), IgM only (10%), IgG and IgM, (23.3%), and IgM and NS1 (1.1%). There was no statistically significant difference in the frequently reported symptoms/signs between dengue seropositive and seronegative febrile adults: headache (71.9% vs.28.1%), muscle pain (73.7% vs. 26.3%), nausea/vomiting (68.4% vs. 31.6%), joint pain (73.5% vs. 26.5%), fatigue (88.9% vs. 11.1%), pallor (66.7% vs. 33.3%) and abdominal tenderness (75.0% vs. 25.0%), all p>0.05. Dengue seropositive and seronegative febrile adults had comparable laboratory parameters. The proportion of seropositive adults with hematological abnormalities compared to seronegative were: anemia (66.7% vs. 33.3%), leucopenia (73.7% vs. 26.3%), and thrombocytopenia (69.6% vs. 30.4%), all p>0.05. We found a high prevalence of dengue seropositivity in this febrile population. Constitutional symptoms and laboratory investigations were comparable between dengue seropositive and seronegative participants Our findings suggest the limited value of clinical and ancillary laboratory parameters in dengue surveillance which justifies a call for improved access to dengue diagnostic assays in endemic regions.

5266

OROPOUCHE VIRUS AS AN EMERGING CAUSE OF ACUTE FEBRILE ILLNESS IN COLOMBIA

Jorge Osorio[1], Karl A. Ciuoderis[2], Michael Berg[3], Lester J. Perez[4], Abbas Hadji[3], Laura S. Perez-Restrepo[5], Leidi Carvajal Aristizabal[6], Kenn Forberg[7], Julie Yamaguchi[7], Andres Cardona[8], Sonja Weiss[7], Xiaoxing Qiu[7], Juan Pablo Hernandez-Ortiz[5], Francisco Averhoff[7], Gavin A. Cloherty[7]

[1]University of Wisconsin, Madison, WI, United States, [2]Colombia/Wisconsin One Health Consortium (CWOHC), Universidad Nacional de Colombia, Medellin, Colombia., Medellin, Colombia, [3]Abbott Diagnostics, Abbott Park, IL, United States, [4]Abbott Diagnostics, Abbott PArk, IL, United States, [5]Colombia/Wisconsin One Health Consortium (CWOHC), Universidad Nacional de Colombia, Medellin, Colombia, [6]Colombia/Wisconsin One Health Consortium (CWOHC), Universidad Nacional de Colombia,, Medellin, Colombia, [7]Abbott Labs, Abbott Park, IL, United States, [8]Colombia/Wisconsin One Health Consortium (CWOHC), Universidad Nacional de, Medellin, Colombia

Arbovirus infections are frequent causes of acute febrile illness (AFI) in tropical countries. We conducted health facility based AFI surveillance at four sites in Colombia (Cucuta, Cali, Villavicencio, Leticia) during 2019-2022. Demographic, clinical and risk factor data were collected from persons with AFI that consented to participate in the study (n=2,967). Serologic specimens were obtained and tested for multiple pathogens by RT-PCR and rapid test (Antigen/IgM), with 20.7% identified as dengue positive from combined testing. Oropouche virus (OROV) was initially detected in serum by metagenomic next generation sequencing(mNGS) and virus target capture in a patient from Cúcuta. Three additional infections from Leticia were confirmed by conventional PCR, sequenced, and isolated in tissue culture. Phylogenetic analysis determined there have been at least two independent OROV introductions into Colombia. To assess OROV spread, a RT-qPCR dual-target assay was developed which identified 87/791 (10.9%) viremic cases in AFI specimens from Cali (3/53), Cucuta (3/19), Villavicencio (38/566), and Leticia (43/153). In parallel, an automated anti-nucleocapsid antibody assay detected IgM in 27/503 (5.4%) and IgG in 92/568 (16.2%) patients screened, for which 24/68 (35.3%) of PCR positives had antibodies. Dengue was found primarily in children (<18 yr) and linked to several clinical manifestations (weakness, skin rash and petechiae), whereas Oropouche cases were associated with the location, climate phase, and odynophagia symptom. Our results confirm OROV as an emerging pathogen and recommend increased surveillance to determine its burden as a cause of AFI in Colombia.

5267

IMPACT OF SARS-COV-2 VARIANTS AND VIRAL LOAD DYNAMICS ON SEVERE COVID-19 AND MORTALITY IN HOSPITALIZED KENYAN ADULT PATIENTS

Evans Raballah[1], Samuel B. Anyona[2], Clinton O. Onyango[2], Qiuying Cheng[3], Elly O. Munde[4], Ivy Hurwitz[5], Philip D. Seidenberg[6], Samuel O. Oyola[7], Collins Ouma[2], Kristan A. Schneider[8], Douglas J. Perkins[3]

[1]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [2]Maseno University, Kisumu, Kenya, [3]University of New Mexico, Center for Global Health, Department of Internal Medicine, Albuquerque, NM, United States, [4]Kirinyaga University School of Health Sciences, Department of Clinical Medicine, Kirinyaga, Kenya, [5]University of New Mexico, Center for Global Health, Department of Internal Medicine, Kakamega, NM, United States, [6]University of New Mexico, Department of Emergency Medicine, Albuquerque, NM, United States, [7]International Livestock Research Institute, Nairobi, Kenya, [8]Department of Applied Computer and Biosciences, University of Applied Sciences Mittweida, Technikumplatz, Mittweida, Germany

While there are a plethora of studies examining factors associated with severe COVID-19 from the Global North, few studies exist for low- and medium-income countries, particularly in sub-Saharan Africa. Such studies are important in the context of differing demographics, co-morbidities, co-infections, and limited pharmaceutical (i.e., remdesivir) and non-pharmaceutical (e.g., mechanical ventilation) interventions. As such, we are conducting a prospective observational study on hospitalized COVID-19 patients (n=246, PCR-confirmed) at Siaya County Referral Hospital, Kenya (6/2020 to present): a high-burden infectious disease region (i.e., malaria, HIV&AIDS, tuberculosis, bacterial infections, etc.). Complete demographic, laboratory, and clinical variables were obtained. Viral load (VL) measurements (log10 copies/1,000 cells) were determined for upper respiratory tract (URT) and peripheral blood (PB) samples on days 0, 3, 6, and 9 (n=193 to present) using RT-qPCR with N1 and RNase P primers and probes. SARS-CoV-2 variants were determined through sequencing and temporal imputation. Disease severity was defined as: severe (SpO2≤90% and/or death), moderate (90%<SpO2≤95%/survival), and mild (95%<SpO2/survival). Mean URT VL was highest for the Omicron variant (P=1.0x10-8), while mean PB VL was highest for the Delta variant (P=1.03x10-6). AIC-based logistic-regression model selection with demographic, clinical, viral variants, and co-morbidities as covariates revealed that PB VL was the strongest predictor of external oxygen requirements (OR=1.58, P=2.16x10-3), severe disease (OR=3.33, P=4.96x10-3), and mortality (OR=1.43, P=0.032). Collectively, these results identify PB VL as the most significant factor associated with adverse outcomes. Interventions aimed at reducing/preventing the SARS-CoV-2 burden in blood, therefore, offer a viable therapeutic option for improved clinical outcomes in this population.

5268

DEVELOPMENT OF A FULLY AUTOMATED PCR ASSAY FOR THE DETECTION OF MPOX VIRUS

Mark Charles Anderson[1], Austin Hodges[1], Kenn Forberg[1], Ana Olivo[1], Ka-Cheung Luk[1], Carolyn Strobel[1], Stanley Piotrowski[1], Peter Wiebe[1], Todd Meyer[1], Danijela Lucic[2], Mary Rodgers[1], Gavin Cloherty[1]

[1]Abbott Diagnostics Division, Abbott Park, IL, United States, [2]Abbott Molecular Diagnostics, Des Plaines, IL, United States

In May of 2022 an outbreak of Clade IIb mpox Virus spread to multiple countries around the world and on July 23rd the WHO declared mpox a public health emergency of international concern due to its spreading to more than 70 non-endemic countries. Due to the rapid and global spread of the disease it became important to rapidly develop high throughput molecular diagnostic assays. Here we report the development of a Research Use Only (RUO) molecular assay (MPXV+) for the detection of mpox virus from lesion swabs and saliva. The MPXV+ assay was developed for the Abbott Molecular m2000 automated platform and employs a dual-target approach in E9L and B6R genes, with internal and external

controls to ensure expected extraction and amplification efficiency. In silico analysis of the MPXV+ oligos predicted 100% sensitivity for both mpox clades and detection of smallpox and vaccinia viruses. Exclusivity analysis at the time of writing predicted no cross-reactivity for 60 other organisms. Two commercially available mpox cultures (NR-2500 and NR-27, BEI) were serially diluted and tested in triplicate to estimate assay limits of detection in pfu/mL and TCID50/mL. Virus cultures were spiked into either UTM or a 1:1 mixture of UTM:saliva to confirm matrix inclusivity. UTM samples from lesions of 35 US CDC confirmed cases and a commercially available longitudinal mpox lesion panel (SLR) were diluted in UTM and tested to assess assay performance against known positive patient samples. Molecular detection of virus culture dilutions showed comparable performance of the MPXV+ assay in both UTM and UTM:saliva. Assay sensitivity was determined to be 1 TCID50/mL suggesting infectious levels of virus are detected. 1:50 dilutions of 35 CDC confirmed mpox lesion swab samples were detected and 1:100 dilutions of commercially sourced samples were detected with the MPXV+ assay. Here we demonstrated the development of a fully automated assay for the detection of mpox virus with sufficient sensitivity to detect infectious levels of virus and 100% concordance to CDC confirmed infections, confirming robust assay performance.

THE ECONOMIC BURDEN OF ILLNESS OF THE GLOBALLY SPREADING CHIKUNGUNYA VIRUS (CHIKV): A SYSTEMATIC LITERATURE REVIEW

Giorgia Tiozzo[1], Gabriel Gurgel[2], Gerard T. Vondeling[3], **Adrianne de Roo**[3]

[1]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands, [2]Asc Academics, Groningen, Netherlands, [3]Valneva, Vienna, Austria

Chikungunya is a disease caused by the arbovirus Chikungunya Virus (CHIKV), which is transmitted to humans by the mosquito species Aedes albopictus and Ae. aegypti. Over the last decades, the geographic spread of these vectors, and therefore the dissemination of CHIKV, has increased due to climate change-related factors. The clinical development of chikungunya has been shown to heavily impact the life quality of the patients, which has led to raised public health concerns. An SLR was performed to identify the evidence of the costs and resource use associated with chikungunya as the impact of the disease remains unclear. The search was conducted on the electronic databases Medline and Embase, and congress abstract repositories. Of the 1,140 records identified, 33 studies reporting outcomes from eleven world regions were included. The most reported study sites were Reunion Island, Colombia, and India. Estimated costs for chikungunya's direct and indirect effects varied greatly between studies and countries. Consultation costs, followed by hospitalization expenditures, were found to constitute the largest proportion of the total direct chikungunya costs. The frequency and duration of hospitalization also ranged significantly across studies. Indirect costs were primarily linked to absenteeism: The highest reported absenteeism rate for a CHIKV-positive population was 62.9%, with the longest median number of days patients were absent from work being 35. In conclusion, chikungunya was found to be associated with a substantial economic burden when considering the costs and frequency of inpatient and outpatient care—as well as absenteeism—for patients reporting symptoms of acute and chronic chikungunya. Moreover, misdiagnosis and mistreatment were identified as confounders to measure the economic disease burden. This highlights the need for more standardized approaches to diagnosing and treating chikungunya.

DEVELOPMENT OF AN INTERDISCIPLINARY, MULTIAGENCY COLLABORATION TO COORDINATE LOCAL RAPID RESPONSES TO DENGUE CASE CLUSTERS IDENTIFIED AND MONITORED THROUGH UNIFIED VECTOR AND HUMAN SURVEILLANCE — PUERTO RICO, JANUARY 2021-2023

Joshua M. Wong[1], Forrest K. Jones[2], Velma K. Lopez[1], Hannah R. Volkman[1], Kyle R. Ryff[3], Roberto K. Barrera[1], Gabriela Paz-Bailey[1], Grayson C. Brown[4], Julieanne Miranda[4], Joanelis Medina Quintana[4], Nexilliane Borrero[4], Jomil Torres-Aponte[5], Mayra Toro Tirado[5], Melissa Marzan[5], Laura E. Adams[1]

[1]Dengue Branch, Division of Vector-Borne Diseases, National Center for Emerging and Zoonotic Infectious Diseases, CDC, San Juan, PR, United States, [2]Epidemic Intelligence Service, Atlanta, GA, United States, [3]Career Epidemiology Field Officers Program, Division of State and Local Readiness, Center for Preparedness and Response, CDC, San Juan, PR, United States, [4]Puerto Rico Vector Control Unit, San Juan, PR, United States, [5]Puerto Rico Department of Health, San Juan, PR, United States

In 2021, the Puerto Rico Dep of Health (PRDH), the Puerto Rico Vector Control Unit, and the CDC Dengue Branch established a collaborative process for identifying and mapping dengue case clusters in Puerto Rico (PR) to develop coordinated local responses aimed at interrupting transmission before an outbreak occured. This group identified clusters based on confirmed or probable dengue cases (2015 CSTE case definition) reported to PRDH or mosquito pools positive by RT-PCR for dengue virus (DENV) 1-4. We defined clusters as 3 DENV detections (including ≥1 case) with disease onset or trap collection date within 21 days and located within 500 meters. Clusters were inactivated when no new detections occurred 6 weeks after the last detection. An analysis of January 2021-2023 identified 63 clusters comprising 409 cases and 97 positive pools. Twenty-six clusters (41%) started in 2021 and 37 (59%) in 2022, with 47 (75%) beginning during June-December. The median size and duration were 5 persons or mosquito pools (IQR 3-8) and 23 days (IQR 13-62). Fifteen clusters (24%) occurred in high-density public housing. Of 78 municipalities, 15 (19%) had ≥1 cluster. As cluster frequency increased during peak months, the group reached a consensus on prioritizing clusters based on size, newly circulating serotypes, public housing, minimal reporting delay, locations with historically high cases, and high-risk neighboring communities. Interventions developed and piloted included placement of autocidal gravid ovitraps, wide-area larvicide spraying, debris clean-up, home inspections, removal of mosquito egg-laying sites, and risk messaging to local authorities. Twenty-seven (43%) clusters received ≥1 intervention. Analyses of mosquito populations in intervention clusters are ongoing and will be included at the time of presentation. This collaboration facilitated rapid response to dengue clusters and highlights the disproportionate burden in public housing. Next steps include automating cluster identification and reporting, standardizing interventions, and critically evaluating unified surveillance and integrated intervention effectiveness.

5271

CORRELATION OF DENGUE TRENDS BETWEEN SENTINEL AND PASSIVE SURVEILLANCE SYSTEMS IN PUERTO RICO, 2012 - 2022

Alfonso C. Hernandez-Romieu[1], Mark Delorey[2], Hannah Volkman[1], Vanessa Rivera-Amil[3], Diego Sainz[4], Jorge Beltran[5], Veronica M. Frsaqueri-Quintana[3], Jomil Torres[6], Melissa Marzan-Rodriguez[6], Aidsa Rivera[1], Olga Lorenzi[1], Carla Espinet-Crespo[1], Yashira Maldonado[1], Roberta Lugo Robles[1], Jorge Munoz[1], Liliana Sánchez-González[1], Gabriela Paz-Bailey[1], Laura Adams[1]

[1]Centers for Disease Control and Prevention, San Juan, PR, United States, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [3]Ponce Health Sciences University, Ponce, PR, United States,

[4]Hospital Auxilio Mutuo, San Juan, PR, United States, [5]Hospital San Lucas, Ponce, PR, United States, [6]Puerto Rico Department of Health, San Juan, PR, United States

The Sentinel Enhanced Dengue Surveillance System (SEDSS) is an ongoing hospital-based active surveillance program for acute febrile illness implemented in 2012 in Southern Puerto Rico and 2019 in the San Juan metropolitan area; however, the representativeness of sentinel surveillance for broader trends is often unknown. We compared laboratory-confirmed dengue cases identified in SEDSS to those reported in the passive arboviral disease surveillance system (PADSS) to determine whether SEDSS could serve as an early warning system and whether dengue trends were similar for both surveillance systems. We analyzed data from dengue epidemic (2012-2014) and non-epidemic (2019-2021) periods to determine the utility of SEDSS under different transmission scenarios. To assess the utility of SEDSS as an early warning system we 1) tested whether the distribution of SEDSS cases was shifted earlier in time relative to PADSS using Cramer-von Mises tests of equality (CvM), and 2) used cross-correlations of lagged SEDSS data relative to PADSS to examine whether cases reported to SEDSS could anticipate those reported to PADSS. During the epidemic period, 738 SEDSS and 10,592 PADSS laboratory-confirmed dengue cases were reported. We observed a trend towards earlier reporting in SEDSS compared to PADSS (CvM p=0.06). The highest cross-correlations in case counts between the two systems were at SEDSS lags of -2, -1, and 0 weeks. During the non-epidemic period, 179 and 1,348 laboratory-confirmed dengue cases were reported to SEDSS and PADSS, respectively. The cumulative distribution of cases in SEDSS was reported earlier compared to PADSS (CvM p=0.02). The highest cross-correlations between counts were at SEDSS lags of -2, -1, and 0 weeks. Plotted together, SEDSS and PADSS followed the same peaks and troughs in dengue cases in both study periods. During epidemic and non-epidemic periods, dengue trends in SEDSS were representative of island-wide trends. SEDSS may serve as an early warning system by detecting increases in incidence up to two weeks before passive surveillance.

5272

COMMUNITY-BASED SERO-PREVALENCE OF CHIKUNGUNYA AND YELLOW FEVER IN THE SOUTH OMO VALLEY OF SOUTHERN ETHIOPIA

Adugna Endale Woldegiorgis

Dire Dawa University, Dire Dawa, Ethiopia

Chikungunya (CHIK) and yellow fever (YF) are becoming major public health threats in East African countries including Ethiopia. This study aimed to assess a community-based sero-prevalence of CHIK and YF in the South Omo Valley of Ethiopia, an endemic area for YF. Between February and June 2018, blood samples were collected from study participants and screened for IgG antibody against CHIK virus (CHIKV) and YF virus (YFV) infections using ELISA. Data were computerized using Epi Data Software v.3.1 and analyzed using SPSS. A total of 360 participants (51.7% males, age range from 6 to 80) participated in this study. The overall sero-prevalence of IgG antibody was 43.6% (157/360) against CHIKV, while it was 49.5% (155/313) against YFV. There was a significant positive correlation between IgG antibodies to CHIKV and YFV (sr = 0.82; P<0.01). Residency in the Debub Ari district (AOR = 8.47; 95% CI: 1.50, 47.74) and travel history to sylvatic areas (AOR = 2.21; 95% CI: 1.02, 4.81) were significantly and positively associated with high sero-prevalence of IgG antibody to CHIKV and YFV, respectively. High sero-prevalence of IgG antibody to CHIKV shows circulation of the virus in the present study area. A low sero-prevalence of IgG antibody to YFV in YF vaccine received individuals is highly concerning from a public health point of view as waning of immune response to YFV infection could result in a periodic outbreak of YF in endemic areas. Nevertheless, the present study has not investigated for possible cross-reactivity of antibody to CHIKV with other alphaviruses and YFV with other flaviviruses and these warrants further studies in the present study area.

5273

SUPERSPREADING OF SARS-COV-2: A SYSTEMATIC REVIEW AND META-ANALYSIS

Clifton D. McKee[1], Emma X. Yu[1], Andrés Garcia[1], Jules Jackson[1], Aybüke Koyuncu[1], Sophie Rose[1], Andrew S. Azman[1], Katie Lobner[2], Emma Sacks[1], Maria Van Kerkhove[3], Emily S. Gurley[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Welch Medical Library, Johns Hopkins School of Medicine, Baltimore, MD, United States, [3]World Health Organization, Geneva, Switzerland

Superspreading events have been a prominent driver of the COVID-19 pandemic, contributing to rapid spread and outbreaks of SARS-CoV-2. Superspreading occurs in settings where transmission is highly efficient and/or when an individual infects many others. We have limited knowledge on the epidemiological contexts and individual-level factors that contribute to SARS-CoV-2 superspreading. To better quantify heterogeneity in SARS-CoV-2 transmission, we performed a systematic review and meta-analysis of transmission events with data on secondary attack rates or contact tracing data for individual index cases published before 9 September 2021, prior to the emergence of variants of concern and widespread vaccination. We reviewed 592 distinct events and 9,883 index cases from 491 papers. “Superspreaders” were identified as index cases causing more than five secondary cases. Meta-analysis of secondary attack rates identified substantial variation across 12 event types/settings: the highest rates were estimated for co-living situations including congregate housing (35%), households (29%), and nursing homes (25%); the lowest rates were estimated for schools (9%), hospital/healthcare (8%), and shopping (1%). There was also substantial variation in attack rates within event types. Among index cases, 67% produced zero secondary cases, 17% had one, and only 3% (287) were superspreaders. Characteristics of index cases were scarce: only 46% reported age, 48% gender, 10% presence/absence of symptoms, and 2% had Ct value. Compared to non-superspreaders, superspreaders were more likely to be adults; only 2 out of 91 superspreaders with data available were aged 12-18 years and none were under 12 years. Extreme heterogeneity in SARS-CoV-2 transmission exists, including between individuals, which remains largely unexplained. Enhanced reporting on transmission events and contact tracing in the literature could help explain some of these differences, but additional research is necessary to gain further insight on the causes of superspreading.

5274

VIRAL ETIOLOGY OF LOWER RESPIRATORY TRACT INFECTIONS IN CHILDREN <5 YEARS OF AGE IN ETHIOPIA: A PROSPECTIVE CASE-CONTROL STUDY

Fiseha Wadilo Wada

Armauer Hansen Research Institute, Addis Ababa, Ethiopia

Lower respiratory tract infections (LRTIs) are a major cause of morbidity and mortality in children worldwide and disproportionally affects Sub-Saharan Africa. Despite the heaviest burden of LRIs in Ethiopia, to date, we have found no published studies reporting comprehensive viral etiology of LRTIs among children in Ethiopia. The objective of this study is to estimate the etiological contribution of respiratory viruses for LRTIs in < 5 years children in Ethiopia. A hospital based prospective case-control study was conducted from September 2019 to May 2022. A one-step Multiplex real-time PCR (Allplex™ Respiratory Panel Assays 1-3) was done to detect respiratory viruses from Naso/Oropharyngeal (NP/OP) swab samples. STATA software version 17 was used for the data analysis. We perform Odds ratio (OR), Attributable fraction among exposed (AFE) and population attributable fraction (PAF) analysis to measure the association of the detected viruses with LRTIs. A total of 210 LRTIs cases and 210 non-LRTI controls were included in the study. The likelihood of detecting one or more viruses from NP/OP was higher among cases than controls (83.8% vs. 50.3%). The multivariate logistic regression showed significantly higher detection rate for RSV A (OR: 14.6, 95% CI: 4.1-52.3), RSV B (OR: 8.1, 95% CI: 2.3-29.1), influenza A virus (OR: 5.8, 95% CI: 1.5-22.9), and PIV 1 (OR:

4.3, 95% CI: 1.1-16.4), among cases when compared with controls. The overall AFE and PAF for RSV A were (93.2% and 17.3%), RSV B (87.7% and 10.4%) and Influenza A virus (82.8% and 6.3%), respectively. Only 2 children were positive for SARS-CoV-2. The mean CT values were lower for all the viruses detected in the cases group with the exception of corona viruses and human rhino viruses. In conclusion, based on our finding, 27.7% LRTIs could be eliminated from children in Ethiopia if RSV were eliminated. Regarding SARS-CoV-2, Children are less likely to get infected by it; therefore in resource limited countries like Ethiopia, the cost-benefit balance of vaccinating under 5 years children against SARS-CoV-2 should be carefully done before launching a vaccination campaign.

5275

SEROPREVALENCE OF DENGUE, CHIKUNGUNYA AND ZIKA AT THE EPICENTER OF THE CONGENITAL MICROCEPHALY EPIDEMIC IN NORTHEAST BRAZIL: A POPULATION-BASED SURVEY

Cynthia Braga[1], Celina M.T. Martelli[1], Wayner V. Souza[1], Carlos F. Luna[1], Maria de Fatima P.M. Albuquerque[1], Carolline A. Mariz[1], Clarice N.L. Morais[1], Carlos A.A. Brito[2], Carlos Frederico C.A. Melo[3], Roberto D. Lins[1], Jan F. Drexler[4], Thomas Jaenisch[5], Ernesto T. A. Marques[6], Isabelle F.T. Viana[1]

[1]Aggeu Magalhães Institute, Oswaldo Cruz Foundation, Recife, Brazil, [2]Federal University of Pernambuco, Recife, Brazil, [3]Pan American Health Organization, Washington D. C., DC, United States, [4]Charité—Universitätsmedizin Berlin; German Centre for Infection Research (DZIF), Berlin, Germany, [5]University of Colorado; Heidelberg University Hospital, DZIF, Denver, CO, United States, [6]Universirty of Pittsburgh, Aggeu Magalhães Institute, Oswaldo Cruz Foundation, Pittsburgh, PA, United States

The Dengue viruses (DENV) serotypes 1, 2, 3 and 4 were re-introduced in the Northeast Brazil one by one from the 1980's until 2010's. Zika (ZIKV) and Chikungunya (CHIKV) viruses were introduced early 2010's and caused large outbreaks in 2015 and 2016. However, the extent of the ZIKV and CHIV outbreaks and the risk factors associated with exposure remains vague. We conducted a stratified multistage household serosurvey among residents aged between 5 and 65 years, in the city of Recife, Northeastern Brazil, from August 2018 to February 2019. The city neighborhoods were stratified according to high, intermediate, and low socioeconomic strata (SES). Previous infections (ZIKV, DENV and CHIKV IgG) were detected by enzyme linked immunosorbent assay (ELISA). Recent ZIKV and CHIKV infections were assessed through IgG3 and IgM ELISA, respectively. Design-adjusted seroprevalence were estimated by age group, sex, and SES. The ZIKV seroprevalences were adjusted according to the accuracy of the tests. Individual and household-related risk factors were analyzed through regression models to calculate the force of infection . Odds Ratio (OR) were estimated as measure of effect. A total of 2,070 residents were investigated. The forces of infection for high SES were lower for all three viruses as compared to intermediary and low SES. Overall DENV seroprevalence was 88.7%. The overall adjusted Zika seroprevalence was 35.6%, 47.4% in the low SES and 23.4% in the high. The overall CHIKV seroprevalence was 35.7 %, with the low SES with a seroprevalence of 38.6% and the high SES with 22.3%. ZIKV seroprevalence increases fast with age while CHIV seroprevalence almost constant through all ages. The serological markers of recent infections for ZIKV and CHIKV were 5% and 3.5 % respectively. In conclusion, our results confirmed continued DENV transmission and intense ZIKV and CHIKV transmission during the 2015/2016 epidemics followed by continued baseline transmission. The study also shows that there is a significant proportion of the population that still susceptible to infections by ZIKV and CHIKV in the region.

5276

INVESTIGATION OF THE MEASLES OUTBREAK IN DJIBOUTI

Warsama Abdi Daher, Houssein Youssouf Darar

National Institute of Public Health, Djibouti, Djibouti

Measles is one of the vaccine-preventable diseases. There are an estimated 9,484,000 cases with 128,000 deaths worldwide in 2021 of which nearly half have been reported in Africa. In addition to this morbidity and mortality, the total cost of a measles epidemic is estimated on average between $9862 and $1,063,936 per outbreak, thus constituting a significant economic burden. The aim of our study was therefore to describe the outbreak of cases and to analyse the epidemiological and spatio-temporal characteristics in order to be able to propose recommendations for measles surveillance and prevention. We therefore undertook a retrospective descriptive study that was conducted on data from measles cases investigated in Djibouti during the period February 2022 to December 2022. A total of 603 cases have been reported throughout Djibouti, of which 326 have been investigated. Of these 326, 204 (63.1%) were biologically confirmed by IgM serology and 2 (0.6%) cases by epidemiological link. The annual incidence of the disease was 171 cases per 1,000,000 population. The sex ratio was 0.91 with mean age of cases of 3 years and 9 months and extremes ranging from 3 months to 50 years. The most represented age group was 1-4 years with 110 (54.2%) cases, and children under 5 years of age accounted for 81.8% of cases. The most observed clinical signs were fever in 98.5% of cases, maculo-papular rash in 98.5% of cases and cough in 92.2% of cases. Among vaccine-age cases, 107 (61.1%) cases were unvaccinated, of which the most represented were 1-4 years of age with 72 (67.3%) cases. One death was reported during this period. In sum, the country's immunization coverage needs to be improved to prevent potential measles outbreaks with a strengthened surveillance system based on systematic early reporting and biological confirmation of all cases.

5277

MOLECULAR EPIDEMIOLOGY OF ACUTE DENGUE AND CHIKUNGUNYA INFECTIONS AMONG FEBRILE PATIENTS VISITING FOUR HOSPITALS IN BOTH URBAN (YAOUNDÉ) AND RURAL (DIZANGUE) SETTINGS FROM CAMEROON

Stella Mariette Nana Ndjangwo[1], Borel Djiappi-Tchamen[2], Ruth Mony[1], Maurice Demanou[3], Joyce Keumezeu-Tsafack[4], Roland Bamou[2], Parfait Awono-Ambene[5], Charles Félix Bilong Bilong[1], Christophe Antonio-Nkondjio[6]

Box 288, Yaoundé, Cameroon., Yaoundé, Cameroon

Dengue and chikungunya are widely distributed in Cameroon but there information on their prevalence in different epidemiological settings are still lacking. This study was undertaken to assess dengue and chikungunya prevalence among febrile patients in urban and rural settings. From December 2019 to September 2021, willing febrile (axillary temperature >38°C) outpatients visiting 4 healthcare facilities in the cities of Yaoundé and Dizangué were screened for malaria, dengue and chikungunya. Patients' clinical symptoms were recorded and their blood samples collected in EDTA tubes were centrifuged at 2000rpm for 10 min in order to obtain plasma, then analyzed using CDC-real-time PCR protocols. A Giemsa-stained tick blood smear was formed for malaria microscopy. Odds ratios were

used to determine the level of association between socio-demographic factors, clinical features and the infection status. Overall, 301 patients were recruited: 198 in Yaoundé and 103 in Dizangue. For dengue, 110 patients were positive 90 (45.45%) in Yaoundé and 20 (19.42%) in Dizangué and the disease' prevalence was higher in urban compared to rural setting. Important prevalence (n= 50, 16.61%) of dengue-malaria co-infection was recorded. For chikungunya, one (0.5 %) patient (Yaoundé) was tested positive after rtRT-PCR. Abdominal and retro-orbital pains were significantly associated to acute dengue infection. All the four dengue serotypes were recorded with a predominance of DENV-3 (35.45%) and DENV-4 (25.45%), with DENV-4 reported for the first time in Cameroon as well as Central Africa Region. In conclusion, this study further confirms endemicity of both dengue and chikungunya in Yaoundé and Dizangue. These data stress the need for active surveillance of cases to prevent outbreaks occurrence across the country.

5278

SEROPREVALENCE OF SARS-COV-2 NEUTRALISING ANTIBODIES AMONG TRAVELERS ENTERING GHANA THROUGH THE MAJOR LAND BORDERS, 2022

Irene Owusu Donkor[1], Elvis S. Lomotey[1], Daniel A. Odumang[1], Ivy A. Asante[1], Cecelia Takyi[1], Ama Nyansema Sekyi -Yorke[1], Emmanuel Frimpong Gyekye[1], Abdul Gafaru Mohammed[2], Emma E. Kploanyi[2], Charles L. Noora[2], Adolphina Addo-Lartey[2], Yvonne Affram[2], Joseph A. Frimpong[3], Magdalene A. Odikro[2], Ernest Kenu[2]

[1]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Ghana, [2]School of Public Health, University of Ghana, Legon, Ghana, [3]School Of Public Health, University of Ghana, Legon, Ghana

High mortality, morbidity, and transmission of circulating SARS-CoV-2 variants have been reported worldwide. The progression of the pandemic in Africa differs based on the pattern of death and the relative contagiousness of the virus. SARS-CoV-2 was introduced into Ghana by travellers followed by subsequent community transmission. Lockdown of air and land borders were two key control strategies. Timely interventions to test and control air border users were implemented, however, land borders remained closed. This cross-sectional study aimed to determine the seroprevalence of SARS-CoV-2 amongst travellers entering Ghana through 10 approved land borders. Persons aged ≥ 18 years into this study. Truck drivers using the land borders and providing goods and services during the pandemic were the main focus in phase one of the study. Sampling later expanded to include all individuals aged ≥ 18 years using the land borders. A questionnaire was administered to each consenting participant and blood samples collected were processed to obtain serum for detection of neutralising antibodies using the WANTAI ELISA kit. Overall seroprevalence was 92.26% (4172/4522). This however varied across the different POEs with the highest in Oseikojokrom (13.74%) and the lowest in Hamile (2.11%). Students and people whose businesses required direct contact with others had 1.84 and 1.16 times higher odds of seropositivity respectively (aOR 1.84: 95% CI 1.04 - 3.24, p= 0.04 and aOR 1.64: 95% CI 1.16-2.32, p=0.005). The odds of seropositivity were 2.19 times higher among vaccinated compared to unvaccinated travellers (aOR 2.19: 95% CI 1.69-2.78, p<0.001). The high neutralising antibodies detected indicates that the majority of persons entering Ghana through the land borders pose little to no risk of community spread. Nearly half of the travellers had received the COIVD-19 vaccination irrespective of which vaccine was administered and travellers' occupation and POE used influenced the seropositivity rates. These findings supported information on the opening of the land borders in Ghana.

ELIMINATION OF HEPATITIS B VIRUS USING ANTIVIRAL PROPHYLAXIS AND VACCINATION IN REMOTE SETTINGS THROUGH LOCALLY ADAPTED, INTEGRATED SERVICES: A MATHEMATICAL MODEL

Belaynew Wasie Taye[1], Patricia C. Valery[2], Sudhamshu K[3], Ananta Shrestha[4], Paul J. Clark[5]

[1]Telethon Kids Institute, Perth, Australia, [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]National Academy of Medical Sciences, Kathmandu, Nepal, [4]Liver Foundation Nepal, Kathmandu, Nepal, [5]University of Queensland, Brisbane, Australia

The Dolpa district of Nepal, has remote geographic landscape, low vaccination coverage, and high prevalence of hepatitis B (HBV) in pregnant women, which creates a condition for perpetuation of high mother to child transmission of the virus. This modeling study assessed the impact of vaccination and third-trimester tenofovir disoproxil fumarate (TDF) prophylaxis on HBV burden and elimination in Dolpa district. This deterministic compartmental model used four possible treatment scenarios: baseline 50% vaccination coverage (scenario I), 50% TDF and baseline vaccination coverage (scenario II), 90% TDF plus baseline vaccination (scenario III), and 90% TDF and birth-dose plus 95% vaccination coverage (scenario IV). The main outcomes for the study were burden of HBV, incidence of HBV, and time to elimination. The study highlights that HBV elimination may not be achieved in Dolpa district by 2100 using the baseline interventions. The use of 90% TDF coverage with the baseline vaccination significantly reduces HBV prevalence and HBV-related mortality and elimination is possible in less than 60 years. Combined implementation and scale-up of 90% TDF and birth-dose and 95% infant HBV vaccination leads to HBV elimination by 2047. In the setting of geographical inaccessibility, a micro-elimination approach for HBV in the remote Dolpa district of Nepal using third-trimester TDF is an effective and equitable approach. This approach is likely to significantly reduce HBV burden and HBV-related mortality even before achieving elimination and partly avoids challenges from the need for cold chain and unaffordable cost of immunoprophylaxis.

5280

THE EPIDEMIOLOGY OF INFLUENZA B VIRUS IN GHANA, 2017 TO 2021

Stephen O. Nyarko[1], Ivy A. Asante[1], Mildred A. Adusei-Poku[1], Nana A. Asante Ntim[1], Richard A. Obeng[1], Esinam A. Amenuvor[1], Jennnifer Wutsika[1], Samuel Ago[1], Roberta Tackie[1], Vanessa Magnusen[1], Linda Boatemaa[1], Gifty Mawuli[1], Joseph A. Nyarko[1], **Ama N. Sekyi-Yorke[1]**, Joseph A. Quarcoo[1], Lorretta Kwasah[1], Yaw Awuku-Larbi[1], Edward O. Nyarko[2], William Asiedu[2], Daniel Mingle[2], Shirley Nimo-Paintsil[3], Naiki Attram[3], Sanders Terrel[3], William K. Ampofo[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]37 Military Hospital, Accra, Ghana, [3]U.S. Naval Medical Research Unit No. 3, Ghana Detachment, Accra, Ghana

Influenza B is characterized by two antigenic lineages: B/Victoria and B/Yamagata. These lineages circulate together with influenza A during seasonal flu epidemics with variation of the year-to-year incidence rates and geographic distribution. This study described the epidemiologic trends of influenza B in Ghana from 2017 to 2021 using surveillance data from the Ghana National Influenza Centre (NIC) sentinel sites. Demographic and laboratory-confirmed influenza data from influenza-like-illness (ILI) cases in Ghana between 2017 and 2021 was obtained from the Ghana NIC. Data was analyzed as detection rates, trends, and regional distribution. The Ghana NIC confirmed 21,539 influenza cases. The detection rate of influenza B was 2,935 per 100,000 (632/21539) and was highest in age groups 0-to-5 years-old and 6-to-15 years-old. Over this five-year period, the detection rate of influenza B was highest in the years 2018 and 2019. However, the years 2017, 2020 and 2021 were below the average rate of 16,028 per 100,000 population (p-value <0.0001). The trend analysis showed that influenza B cases increased from epidemiological week 35

(in the month September) for the years under review. In 2017 and 2018, both influenza B lineages were co-circulating, but from 2019 to 2020, the B/Victoria lineage dominated. Few influenza B infections (Victoria=1; Yamagata=1) were detected in 2021. Influenza B infections were sporadic with variable geographic (regional) distribution in Ghana. Secondary analysis of data from this five-year period helped better understand the frequency and distribution of influenza B in Ghana. Additionally, information from this five-year period was shared with the World Health Organization (WHO) Global Influenza Surveillance and Response System (GISRS) and contributed to recommendations for which influenza strains were incorporated into the southern hemisphere seasonal influenza vaccine. Findings from this surveillance activity highlight the importance for ongoing influenza surveillance and monitoring of the antigenic strains in circulation

A PROPOSAL FOR UTILIZATION OF PREGNANCY AS AN OPPORTUNITY FOR HCV ELIMINATION AND ERADICATION

Sarah Boudova, Danielle Tholey, Jonathan Fenkel, Richard Derman, Rupsa Boelig

Thomas Jefferson University, Philadelphia, PA, United States

Hepatitis C Virus (HCV) is a major cause of morbidity and mortality globally. Since the development of highly effective direct acting antivirals, the WHO has set a goal of HCV elimination by 2030. Key to this strategy are increased screening and treatment for HCV. Pregnancy and the postpartum period represent a unique time when underserved populations globally have increased contact with the healthcare system. We propose a model in which antenatal care is used to maximize case identification, treatment, and prevention. Pregnant individuals are an ideal sentinel population for HCV surveillance. Contact with the healthcare system is driven by the pregnancy, rather than disease, and thus asymptomatic carriers can be identified. The population is well distributed geographically and socioeconomically, reducing potential sampling bias. Additionally, the infrastructure already exists, as antenatal centers routinely screen for other diseases like HIV. Universal screening in pregnancy can provide data on population level disease exposure and be used to identify geographic hot spots. Once cases are identified, we argue that pregnancy presents an opportunity for intervention. While treatment during pregnancy is not currently WHO approved, clinical trials are underway examining the safety of the direct acting antivirals antepartum. In the interim, identification of infection during pregnancy allows for optimization of the treatment cascade postpartum. It also ensures the exposed newborn and other close contacts can be identified and connected with HCV screening. Finally, we propose that pregnancy can be used as a time for prevention measures, connecting patients to needle exchanges, counseling on risk reduction and providing education on the disease. As new technologies are developed, it may also represent an ideal time to perform vaccination. Taking advantage of patient engagement and existing infrastructure, pregnancy presents a unique opportunity to intervene in the fight for HCV eradication.

ASSESSING JAPANESE ENCEPHALITIS VIRUS RISK IN ASIA USING HIGH-RESOLUTION REMOTELY SENSED DATA AND MACHINE LEARNING

Alan Costello, Sean M. Moore

University of Notre Dame, Notre Dame, IN, United States

Japanese encephalitis virus (JEV) is a mosquito-borne virus endemic to large parts of Asia and the western Pacific and is the predominant cause of vaccine-preventable encephalitis in the region. JEV is estimated to have caused more than 20,000 deaths in 2019, but fewer than 1% of infections result in symptomatic disease. Occurrence data is sparse despite acute encephalitis syndrome (AES) surveillance in most countries, as cases are not always laboratory confirmed and spatially detailed data is typically not published. To enhance our understanding of the prevalence and distribution of JEV in Asia we conducted a literature review of available occurrence data and compiled all records which could be geocoded. We use this occurrence data with high-resolution remotely sensed covariates and a convolutional neural network (CNN)-based approach to model probability of occurrence at significantly improved resolution and scale over past research. The CNN method has been demonstrated to excel in similar spatial prediction tasks with sparse data and allows us to predict probability of occurrence at 100m x 100m resolution, a first for the region. Our 13 covariates include climatic and population data, as well as land use, vector habitat, and animal density rasters. Preliminary results are promising, with a 0.72 probability of occurrence predicted for the validation dataset, which contains 15% of total JEV observations withheld from model training and testing. These preliminary outputs focus on a subset of the region including the Indian subcontinent and surrounding area, successfully predicting higher probability in Uttar Pradesh, Bihar, and Bangladesh where we have high density of occurrence records, but also in Andhra Pradesh, Telangana, and parts of Myanmar where data is severely lacking. We expect further improvement in model accuracy as we incorporate more data and further develop the model. Our approach provides a more detailed view of the spatial distribution of JEV and has the potential to inform targeted intervention and control strategies for the disease, ultimately helping to reduce the burden of Japanese Encephalitis in these endemic regions.

INVESTIGATION OF SEVERE DENGUE OUTBREAK IN MAUMERE, EAST NUSA TENGGARA, INDONESIA IN 2020: CLINICAL, SEROLOGY, AND VIROLOGICAL FEATURES

Marsha Santoso[1], R Tedjo Sasmono[2]

[1]Exeins Health Initiative, Jakarta, Indonesia, [2]Eijkman Center for Molecular Biology, Cibinong, West Java, Indonesia

Dengue, an acute febrile disease caused by dengue virus (DENV) infection, is endemic to Indonesia. The country continues to see cyclical outbreaks throughout the years. During early 2020, outbreak of severe dengue occurred in Maumere, Sikka district, East Nusa Tenggara province. Investigation was conducted to understand the cause and characteristics of the outbreak. During the outbreak from February to June 2020, dengue patients were recruited in TC Hillers Hospital, Maumere and sera were collected. Clinical and hematological data were acquired from the patients and DENV infection was confirmed using NS1 antigen and/or RT-PCR detection. The patients' serological status was determined using IgG/IgM ELISA and plaque reduction neutralization test (PRNT). DENV serotyping and Envelope gene sequencing were performed to identify the serotype and genotype of the viruses causing outbreak. Dengue infections were virologically confirmed in 96 (72.2%) out of 133 patients enrolled. Most patients (88.7%) were children under the age of 18 years. Most cases were dengue hemorrhagic fever/dengue shock syndrome while only 5.8% were dengue fever. A majority (92.6%) of these cases were secondary infections. The dominant serotype was DENV-3 (87.3%), followed by DENV-4 (7.0%), DENV-1 (2.8%), and DENV-2 (2.8%). PRNT on DENV-3 secondary infections patients detected the presence of DENV-2 and DENV-4 neutralizing antibodies. Phylogenetic analysis revealed close evolutionary relationship of Maumere DENV to viruses from other Indonesian regions, especially Bali and Kupang. The presence of anti-dengue antibodies for multiple serotypes suggests a history of dengue transmission, with the serotype shift, likely from introduction through travel, as a possible contributor to this outbreak. The high proportion of anti-dengue IgG in young children also demonstrates a high infection rate in the area which may contribute to disease severity. The severe dengue outbreak in Maumere is caused by DENV-3 which were introduced from nearby islands. The secondary infection of this serotype most likely contributes to the severity of the disease during the outbreak.

5284

PREVALENCE OF ANTI-VZV AMONG SAMPLE OF MEDICAL UNDERGRADUATES IN SRI LANKA: EXPLORING THE VALUE OF 'RECALLED HISTORY OF CHICKENPOX' AS AN INDICATOR OF IMMUNITY

Nayani Weerasinghe[1], Gaya Wijayaratne[1], Ajith Nagahawatte[1], Subodha Wickramasinghe[1], Harshani Thabrew[1], Gayani Tillekeratne[2], Sunethra Gunasena[1]

[1]Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, [2]Duke Global Health Institute, Durham, NC, United States

Immunity to varicella zoster virus (VZV) is indicated by the presence of antibody to VZV (anti-VZV). Chickenpox vaccine is not included in the National Immunization Program of Sri Lanka and immunity to VZV usually develops following natural infection, unless an individual receives vaccination in the private sector. Recalled history of chickenpox is often used as an indicator of immunity when deciding post-exposure prophylaxis. The objective of this study was to determine the performance of 'Recalled history of chickenpox' as an indicator of immunity. A cross-sectional study was carried out with convenient sampling involving medical undergraduates at a state university in Sri Lanka from August to October 2020. Epidemiological data and blood sample for anti-VZV (by anti-VZV IgG ELISA, Euroimmune, Germany) was collected. Total of 142 undergraduates participated in the study. Median age was 22 years (IQR 22 -23). Almost half (45.1%, 64/142) gave history of chickenpox without history of vaccination. Another 7% (10/142) undergraduates who had no history of illness had taken chickenpox vaccination, with 60% (6/10) of them getting a single dose of vaccine. The balance 47.9% (68/142) had neither history of chickenpox nor vaccination. Of the 64 undergraduates who had chickenpox, 43.8% (28/64) had it at the age < 10 years, 18.8% (12/64) at 10 to 15 years and 34.4% (22/64) at > 15 years. Anti-VZV was detected in 48.6% (69/142) indicating immunity to chickenpox, including 91.3% (63/69) with history of chickenpox and 7.2% (5/69) with history of vaccination. Anti-VZV was detected in one (1.4%) who had no history of chickenpox or vaccination. Positive recalled history of chickenpox had a sensitivity 98.4%, specificity 98.5%, positive predictive value 98.4% and negative predictive value 98.5% for the presence of anti-VZV. Immunity to VZV is detected in less than 50% of the medical undergraduates at a state university in Sri Lanka, in majority following natural infection. Positive recalled history of chickenpox has a good predictive value of immunity and recalled history of chickenpox can be used in deciding the post exposure prophylaxis.

5285

HIGH RISK OF DENGUE AND CHIKUNGUNYA VIRUS FOUND AMONGST CHILDREN LIVING IN INFORMAL URBAN SETTLEMENTS IN MAKASSAR, INDONESIA

Joelle I. Rosser[1], John J. Openshaw[2], Audrie Lin[3], Fiona Barker[4], Nursehang Tamodding[5], Murni Amiruddin[5], Nurul Pausi Emelia Abdullah[5], Ansariadi Ansariadi[5], Karin Leder[1], Isra Wahid[5], Stephen Luby[1]

[1]Stanford University, Stanford, CA, United States, [2]University of Vermont, Burlington, VT, United States, [3]Penn State, Philadelphia, PA, United States, [4]Monash University, Melbourne, Australia, [5]Universitas Hasanuddin, Makassar, Indonesia

Increases in dengue (DENV) and chikungunya (CHIKV), viruses transmitted by Aedes aegypti and Aedes albopictus, have been highlighted as one of the most alarming health impacts of climate change. Increasing temperatures are ideal for Aedes life stages and extreme weather events, such as droughts and floods, increase water insecurity and promote Aedes breeding habitats. Additionally, the built environment and under-resourced water and trash management systems in informal settlements likely play critical roles in mediating the risk of Aedes-transmitted arboviruses. However, dengue and chikungunya risk in informal settlements with these dual risks from the built environment and climate vulnerability have not been well studied. In 12 informal settlements in Makassar, Indonesia, we conducted annual testing for prior dengue and chikungunya infection by Abcam IgG ELISA in children under 5 years old. We then calculated annual incidence using the catalytic formula with age stratified seropositivity rates and using the seroconversion rate in children tested both years. Amongst 154 children tested during at least one of two testing campaigns in 2019 and 2020, seropositivity was 32% for dengue and 3% for chikungunya. We estimated the dengue annual incidence to be approximately 10-18%. We also found that children living in houses made of porous wall or floor materials were less likely to have evidence of a past dengue or chikungunya infection (OR=0.5; p<0.05). Additionally, children living in households with trash collection were less likely to be seropositive (OR=0.4; p<0.05) compared to those that disposed of their household trash locally in the settlement Changes in house construction and trash disposal practices offer opportunities for interventions to reduce dengue and chikungunya transmission in this highly vulnerable population.

GENOMIC CHARACTERIZATION OF SARS-COV-2 FROM AN INDIGENOUS RESERVE IN MATO GROSSO DO SUL, BRAZIL

Izabela Mauricio de Rezende[1], Vinicius Navarini[2], Lais Albuquerque de Oliveira[2], Silvana Beutinger Marchioro[3], Alex Jose Leite Torres[3], Julio Croda[4], Crhistinne Cavalheiro Maymone Gonçalves[5], Mariana Garcia Croda[2], Luiz Henrique Ferraz Demarchi[6], Joilson Xavier[7], Emerson de Castro Barbosa[8], Mauricio Lima[8], Vagner Fonseca[9], Felipe Campos de Melo Iani[8], Talita Adelino[8], Flávia Figueira Aburjaile[10], Marta Giovanetti[11], Luiz Alcantara[12], Simone Simionatto[2]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Universidade Federal da Grande Dourados, Dourados, Brazil, [3]Universidade Federal da Bahia, Bahia, Brazil, [4]Universidade Federal do Mato Grosso do Sul, Campo Grande, Brazil, [5]Secretaria Estadual de Saúde do Mato Grosso do Sul, Campo Grande, Brazil, [6]Laboratório Central de Saúde Pública de Mato Grosso do Sul, Campo Grande, Brazil, [7]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [8]Fundação Ezequiel Dias, Belo Horizonte, Brazil, [9]Pan American Health Organization - PAHO, Brasília, Brazil, [10]Secretaria de Estado do Mato Grosso do Sul, Campo Grande, Brazil, [11]Rene Rachou, Fundação Oswaldo Cruz and Sciences and Technologies for Sustainable Development and One Health, University of Campus Bio-Medico, Belo Horizonte and Rome (Italy), Brazil, [12]Rene Rachou, Fundação Oswaldo Cruz, Belo Horizonte, Brazil

The COVID-19 pandemic had a major impact on indigenous populations. Understanding the viral dynamics within this population is essential to create targeted protection measures. A total of 204 SARS-CoV-2 positive samples collected between May 2020 and November 2021 from an indigenous area in Mato Grosso do Sul (MS), Midwestern Brazil, were screened. Samples were submitted to whole genome sequencing using the Nanopore sequencing platform. Clinical, demographic, and phylogenetic data were analyzed. We found the co-circulation of six main SARS-CoV-2 lineages in the indigenous population, with the Zeta lineage being the most prevalent, followed by B.1.1 (an ancestral strain), Gamma, and Delta. The estimated indigenous population mortality rate was 1.47%. Our results revealed that multiple independent SARS-CoV-2 introduction events had occurred over time, probably due to indigenous mobility since the villages studied here are close to urban areas in MS, and people are in constant movement between both areas. The mortality rate was slightly below the estimation for the state in the period studied, which we believe could be related to the low number of samples evaluated, the underreporting of cases and deaths among the indigenous population, and the inconsistency of secondary data available for this stud. In this study, we showed the circulation of multiple SARS-CoV-2 variants in the indigenous population, which should be isolated and protected as they belong to the most fragile group due to their socioeconomic and cultural disparities. We reinforce the need for constant genomic surveillance to monitor and prevent the spread of new emerging viruses and to better understand the viral dynamics in these populations, making it possible to direct specific actions.

METAGENOMIC SEQUENCING REVEALS EXTENSIVE DIVERSITY OF RNA VIRUSES IN WESTERN AUSTRALIAN MOSQUITOES

Binit Lamichhane[1], Mang Shi[2], Craig Brockway[3], Kimberly Evasco[3], Jay Nicholson[3], Peter Neville[3], Andrew Jardine[3], Chisha Sikazwe[4], Avram Levy[4], John Mackenzie[5], David Smith[4], Allison Imrie[1]

[1]The University of Western Australia, Perth, Australia, [2]Sun Yat-sen University, Guangzhou, China, [3]Department of Health, Perth, Australia, [4]PathWest Laboratory Medicine, Perth, Australia, [5]Curtin University, Perth, Australia

Mosquitoes harbour a wide diversity of microorganisms, including insect-specific viruses and viruses of public health importance. In recent years, metagenomic approaches have enhanced the study of these widely diverse and complex virus populations in field-collected mosquitoes. We used metagenomics to characterize the infectome in mosquitoes trapped as part of the Western Australia (WA) arbovirus surveillance program. Firstly, we performed high-resolution metagenomic sequencing on six mosquito species associated with medically important viruses: Aedes vigilax, Culex annulirostris, Cx. australicus, Cx. globocoxitus, Cx. molestus and Cx. quinquefasciatus. We identified 41 RNA and one DNA viral species from 19 families, including 13 novel viruses. Culex mosquitoes exhibited a significantly higher diversity of viruses than Aedes; no virus was shared between the two genera. We observed heterogeneous distribution of viruses between geographical regions and between closely related species suggesting the possible role of geography and host species in shaping virome composition. Wolbachia bacteria were detected in three members of the C. pipiens complex, excluding C. globocoxitus. Secondly, we characterized viruses from cytopathic effect (CPE)-positive tissue culture supernatants obtained by inoculation of mosquito homogenate, in which flaviviruses and alphaviruses were excluded via fixed-cell ELISA using virus-specific monoclonal antibodies. We characterized whole genomes of 91 RNA viruses belonging to 11 species from five viral families. The viruses included Gan Gan virus, associated with mild human disease, and Batai, Wallal and Warrego viruses, known to cause animal disease. We also identified one Murray Valley encephalitis virus and a Ross River virus, both known to cause human disease and a possible limitation of the screening ELISA. Follow-up epidemiological investigations are needed to determine whether the other identified viruses infect humans or other animals. In summary, we have used an unbiased approach to expand and understand the diversity of RNA viruses and other microorganisms in WA mosquitoes.

5288

GENETIC CHARACTERIZATION OF INFLUENZA AND SARS-COV-2 IN DOD BENEFICIARIES DURING THE 2021-2022 SEASON

WILLIAM GRUNER, ANTHONY FRIES, DEANNA MUEHLEMAN, CAROL GARRETT, JENNIFER MEYER, KELSEY LANTER, PADRAIC FANNING, JAMES HANSON, PETER WASIK, ELIZABETH MACIAS

DCPH-DAYTON, WRIGHT-PATTERSON AFB, OH, UNITED STATES

The Department of Defense (DoD) Global Respiratory Pathogen Surveillance Program conducts testing on respiratory specimens from a worldwide network of sentinel sites using PCR-based assays and next-generation sequencing (NGS) to detect and characterize respiratory pathogens. Analyses aid in the annual selection of influenza vaccine strains and help define the impact of influenza and SARS-CoV-2 in the DoD. The program collects respiratory specimens and metadata from DoD active duty and beneficiaries with influenza-like or COVID-19-like illness symptoms across 100+ global sentinel sites. PCR confirmed influenza and SARS-CoV-2 positive specimens are further characterized by NGS. In combination with partner laboratory data, phylogenetic analyses and lineage determinations are performed to assess the genetic changes occurring in these viruses. 1,348 influenza viruses were analyzed, with 1,337 A(H3N2), 10 A(H1N1) pdm09, and one B/Yamagata. Among A(H3N2) viruses, one was clade 3C.2a1b.1a and the rest were clade 3C.2a1b.2a2, with 963 sharing D53G, 309 sharing D53N, 23 sharing E50K, 24 sharing S205F, and 17 with no further subgrouping. Two of the A(H1N1)pdm09 viruses were clade 6B.1A.5a1 and 8 were clade 6B.1A.5a2. The B/Yamagata virus was clade Y3. For SARS-CoV-2, lineages were determined for 10,381 sequences, including 1 Alpha, 1,864 Delta, 3,794 BA.1, 1,950 BA.2, 622 BA.2.12.1, 18 BA.3, 259 BA.4, 65 BA.4.6, 1,802 BA.5, and 6 recombinant viruses. Influenza activity during the 2021-2022 season was elevated from the previous season but lower than seasons before that. Strains for the 2022-2023 Northern Hemisphere vaccine include a clade 3C.2a1b.2a2 virus for A(H3N2), a clade 6B.1A.5a2 virus for A(H1N1)pdm09, a clade V1A.3a1 virus for B/Victoria, and a clade Y3 virus for B/Yamagata. 99.9% of A(H3N2) viruses, 80% of A(H1N1)pdm09 viruses, and the one B/Yamagata virus were the same clade as these vaccine strains. Many A(H3N2) clade 3C.2a1b.2a2 subgroups emerged. Predominance of SARS-CoV-2 variants throughout the season shifted from Delta to BA.1 to BA.2 to BA.5, with most of the circulation and diversity falling within the Omicron lineage.

5289

A UNIQUE AMPLICON SEQUENCING TECHNOLOGY FOR INFECTIOUS DISEASE: LONG AND SHORT-READ SOLUTIONS

Andrea Spencer, Tiffany Stedtfeld, Cayley Higbee, Mollie Schubert, Jessica Woodley, Shengyao Chen, Thomas Osborne, Jordan RoseFigura, Laurie Kurihara

Integrated DNA Technologies, Ann Arbor, MI, United States

The COVID-19 pandemic demonstrated that accurate, rapid, and sensitive viral genome sequencing is critical to directing the global response to disease and pandemics. IDT's xGen™ Amplicon technology allows over 3,500 target specific primers in a single multiplexed PCR reaction. This design can generate super-amplicons that maintain target coverage when a primer drop-out occurs due to novel viral mutations. Super-amplicons form when amplicon primers produce 2X or greater sized amplicons. A single Wuhan-1-based panel design for SARS-CoV-2 provided complete coverage for all known SARS-CoV-2 variants. The xGen Amplicon technology was initially developed for short read sequencing (PE-150) with Illumina platforms. Here we show that the xGen Amplicon technology also provides sequencing solutions with long read sequencing (up to 4kb read length) using the Oxford Nanopore MinIon (ONT). For HIV we developed an xGen Amplicon panel using the reference genome HXB2. We tested five variants with 91-94.3% identity to HXB2. Coverage for the short read panel ranged from 77-90%. Gaps in coverage were mainly in the env region. We hypothesized that super-amplicons are produced but are too long for Illumina sequencing. To confirm this, HIV amplicon products of the multiplex PCR were subjected to fragmentation and library prep followed by Illumina sequencing. Coverage was improved to greater than 96% for all variants; however a significant drop in viral mapping resulted. To circumvent the low mapping rate, an xGen Amplicon ONT panel for HIV was designed using the same panel design described above. Long read sequencing with the MinIon generated coverage greater than 90% for the four HIV variants that were tested, while a high viral mapping rate was maintained. This demonstrates the ability of the panel to generate amplicons that can be used to sequence highly divergent regions of rapidly evolving viruses even when regions of the genome diverge significantly from the design genome. We are continuing with this approach for a number of other viruses, including Chikungunya, Zika, and Dengue.

RE-EMERGENCE OF COSMOPOLITAN GENOTYPE OF DENGUE VIRUS SEROTYPE 2 IN SOUTHERN VIETNAM

VI THUY TRAN1, RHYS P. D. INWARD2, BERNARDO GUTIERREZ GRANJA2, NGUYET MINH NGUYEN1, PHONG THANH NGUYEN3, TAM THI CAO3, MORITZ U. G. KRAEMER2, KIEN THI HUE DUONG1, SOPHIE YACOUB1

1OXFORD UNIVERSITY CLINICAL RESEARCH UNIT, HCM, VIET NAM, 2DEPARTMENT OF BIOLOGY, UNIVERSITY OF OXFORD, OXFORD, UNITED KINGDOM, 3HOSPITAL FOR TROPICAL DISEASES, HCM, VIET NAM

Dengue is a mosquito-borne viral infection caused by one of the four dengue serotypes (DENV1-4). Each serotype is subdivided into several genotypes. Asian 1 of dengue virus serotype-2 (DENV-2), has been the dominant genotype in southern Vietnam for the last decade. In this study, we have identified new DENV-2 lineages of cosmopolitan genotype in Ho Chi Minh City, not previously detected in Vietnam before (samples from 2017-2022). We infer the likely transmission routes of these new DENV-2 lineages into Vietnam from other South and Southeast Asian countries and when these events occurred. Of 45 DENV-2 samples, taken between 2017 and 2022, we identified 28 (62%) were Cosmopolitan genotype and 17 (37.7%) were Asian I genotype. The full DENV-2 phylogeny analysis will be presented, including the probable route of introduction of these viruses into Ho Chi Minh City and surrounding areas, the approximate timing of these events, and current outbreak dynamics. This re-emergence of the Cosmopolitan genotype, with new lineages, prompts an urgent need to update dengue serotyping techniques for surveillance in the region as well as set up studies on evolution, and transmission dynamics of this virus.

5291

DENGUESEQ: DEVELOPMENT AND VALIDATION OF A PAN-SEROTYPE WHOLE GENOME AMPLICON SEQUENCING APPROACH FOR DENGUE VIRUS

Chantal B.F. Vogels[1], Chrispin Chaguza[1], Mallery I. Breban[1], Lauren Paul[2], Verity Hill[1], Afeez Sodeinde[1], Emma Taylor-Salmon[3], Isabel M. Ott[4], Mary E. Petrone[5], Abigail J. Porzucek[1], Sylvia Bunch[6], Natalia Cano[6], Rayah Jaber[6], Charles Panzera[6], Ian Stryker[6], Julieta Vergara[6], Rebecca Zimler[7], Edgar Kopp[6], Lea Heberlein[6], Andrea Morrison[7], Scott Michael[2], Nathan D. Grubaugh[1]

[1]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [2]Department of Biological Sciences, Florida Gulf Coast University, Fort Myers, FL, United States, [3]Department of Pediatrics, Yale School of Medicine, New Haven, CT, United States, [4]Department of Immunobiology, Yale School of Medicine, New Haven, CT, United States, [5]Sydney Institute for Infectious Diseases, School of Medical Sciences, The University of Sydney, Sydney, Australia, [6]Bureau of Public Health Laboratories, Division of Disease Control and Health Protection, Florida Department of Health, Tampa, FL, United States, [7]Bureau of Epidemiology, Division of Disease Control and Health Protection, Florida Department of Health, Tallahassee, FL, United States

Amplicon-based sequencing (PrimalSeq) was developed in response to the Zika virus epidemic due to difficulties generating complete genomes using metagenomic approaches. Later this approach was adapted as the primary sequencing method for SARS-CoV-2 (i.e. the "ARTIC" protocol). Investments in global genomic infrastructure resulted in a significant increase in amplicon sequencing capacity that can be utilized beyond SARS-COV-2, by swapping out virus-specific components such as primer schemes. Increased genomic surveillance of other viruses of public health concern, such as dengue virus, is needed to reduce the future burden of disease. Particularly, genomic surveillance of dengue virus can help to monitor the roll out of novel control strategies such as vaccines and release of mosquitoes carrying the virus-inhibiting Wolbachia bacterium. However, the majority of currently available sequences are partial, while complete genomes are needed to monitor and refine novel control tools. In this study, we developed and validated a pan-serotype whole genome amplicon sequencing approach for dengue virus. We sequenced a panel of virus stocks as well as clinical specimens from Florida to validate our approach with genetically diverse dengue viruses spanning the defined genotypes within each of the four serotypes. We show that the dengue primer schemes can be "plugged" into existing amplicon sequencing workflows, with high genome coverage across all four serotypes at a range of RNA titers (threshold of ~100 RNA copies/µL). The primer schemes can be either used as a serotype-specific assay (serotype known) or mixed into a unified pan-serotype assay (serotype unknown), with similar sensitivity. Our approach can help laboratories to quickly adapt their existing amplicon sequencing workflows to improve genomic surveillance of dengue virus.

5292

EVOLUTION AND CIRCULATION OF SARS-CO-V2 OMICRON SUBVARIANTS IN ODISHA STATE, INDIA, NOVEMBER 2021 TO NOVEMBER 2022

Ira Praharaj, Subhra Subhadra, Swatismita Priyadarshini, Swagatika Panda, Jyotsnamayee Sabat, S. Kombiah, Sanghamitra Pati

Indian Council of Medical Research Regional Medical Research Centre, Bhubaneswar, India

Omicron Variant of Concern (VOC) & its subvariants are characterized by immune evasion and reinfection. We present 1 year data (November 2021 to November 2022) of circulating SARS CoV2 variants in Odisha, India. We included 855 samples from SARS CoV2 positive patients by real-time RT-PCR referred to the Virus Research & Diagnostic Laboratory at the ICMR Regional Medical Research Centre, Bhubaneswar. Next-generation sequencing for SARS-CoV-2 was performed on Oxford Nanopore MinION Mk1C with Midnight protocol for library preparation. Bioinformatic pipeline included ARTIC field bioinformatics, lineage classification was done with PANGOLIN and Nextclade. Demographic data, history of vaccination & prior SARS CoV2 infection was included for analysis. Predominant circulating VOC in Odisha in November & December 2021 was B.1.617.2 in 87.3% and 58.8% respectively of sequenced samples while Omicron (B.1.1.159) VOC was detected in 3.23% of specimens in December 2021. BA.1 and BA.2 subvariants dominated between January-May 2022 and corresponded to a peak in COVID19 cases & high positivity between January-March 2022. A shorter peak in reported cases in July-August 2022 corresponded with predominance of BA.2.75 subvariant (40.3% and 60% of sequenced samples July & August 2022 respectively). BA.4, BA.5 were detected in limited samples (5% and 1% July 2022). XBB and further subvariants (XBB.1, XBB.2, XBB.3) were detected from September-November 2022 but did not correspond with increased cases or hospitalization. In cases of SARS CoV2 reinfection(N=166), the commonest subvariants were BA.2 (24.1%), BA.2.75 (24.7%) & XBB (10.8%) corresponding to the months in which these were the predominant subvariants. Reinfections were more common in ages 20-40 yrs and 40-60 yrs with few cases in >60 yrs. Primary 2-dose vaccination against SARS CoV2 was complete in all the reinfection cases, but in 39.2% of reinfections, booster 3rd dose had not been administered. In conclusion, Omicron and its evolving sub-variants are the current circulating VOC in our region in India and associated with considerable number of SARS CoV2 reinfections.

DEVELOPING A DENGUE VIRUS LINEAGE CLASSIFICATION SYSTEM TO IMPROVE GENOMIC SURVEILLANCE

Verity Hill, Chrispin Chaguza, Chantal Vogels, Nathan Grubaugh

Yale University, New Haven, CT, United States

Last year, dengue virus caused nearly three million cases in the Americas. As climate change continues and Aedes species increase their geographical range, more populations are at risk of infection, leading to an increase in the disease burden. Interventions, including Wolbachia infection and vaccinations, are likely to be impacted by viral genetic diversity but dengue virus genetic diversity is currently not well described. Dengue virus genomes are categorized as one of four serotypes, and each of those have several

genotypes. However, some sequenced dengue viruses do not cluster with the defined genotypes, and they do not capture most transmission dynamics. For example, most of the DENV1 sequences in the Americas fall into the DENV1-V genotype, and so details of how DENV1 spreads between and within countries using only the genotype designations are obscured. Further, any impact of pharmaceutical or biological interventions is not easily monitored, and both would require slower and more complex phylodynamic analyses. Following previous work on SARS-CoV-2 and Rabies virus, we proposed a hierarchical lineage classification system to address this issue. We built on the existing serotype-genotype system to maintain ties with the existing dengue virus research community; and designated all publicly available dengue virus genomes, including new genomes from the Caribbean and Florida. We have also written an accompanying software tool to enable other groups to assign new sequenced viruses for genomic surveillance programs. We then apply this lineage system to explore local and regional dengue virus transmission dynamics without the need for complex phylodynamic analyses.

5294

IDENTIFICATION OF GENES INVOLVED IN THE TYPE-I INTERFERON RESPONSE ELICITED BY THE LIVE-ATTENUATED JAPANESE ENCEPHALITIS VIRUS SA14-14-2 VACCINE

Dana L. Vanlandingham, Natalia Costa Ball, Joshua Willix
Kansas State University, Manhattan, KS, United States

Japanese encephalitis virus (JEV) is a mosquito-borne flavivirus that has both human and veterinary public health significance. The safe and highly effective SA14-14-2 live-attenuated vaccine (LAV) can elicit protective immunity with one single immunization and plays a major role in the control of human JE. To date, little is known about the mechanism(s) contributing to the high immunogenicity of JEV SA14-14-2 LAV. Such knowledge can be translated to support the development of next-generation candidate JEV LAV and has important implication for the development of candidate LAVs for encephalitic flaviviruses. We undertook the genome wide CRISPR-Cas9 knock-out screening of human A549 (GeCKO-A549) cells infected with the JEV SA14-14-2 strain, as a model system to investigate the host responses following immunization with JEV LAVs. Surviving cells were harvested, followed by the extraction of genomic DNA and next-generation sequencing analysis. Unique genes were selected based on the gene enrichment in the JEV resistant GeCKO-549 cells as compared to the control cells. There was correlation between survival of GeCKO-A549 cells and deletion of tyrosine kinase 2, interferon alpha subunit 1, interferon beta receptor subunit 2, and signal transducer and activator of transcription 1 (STAT1). All four genes are associated with type-I interferon response against JEV. Although STAT1 knockout did not result in the surviving phenotype, STAT1 gene was highly ranked. In comparison with wild-type JEV strains, the SA14-14-2 vaccine strain is capable of eliciting a broader spectrum of type-I IFN responses, providing a putative molecular basis for the high immunogenicity of the empirically developed human JE live-attenuated vaccine (LAV). The knowledge can be translated to support the rational design of second-generation candidate LAVs to control human and swine JE.

5295

DOES TIME MATTER IN EBOLAVIRUS RESURGENCE? ELUCIDATING TIMEFRAME REQUIRED FOR REACTIVATION OF EBOV WITHIN HUMAN SURVIVORS AND BATS POPULATION

Ifeanyi Omah, John T. McCrone, Áine O'toole, Andrew Rambaut
University of Edinburgh, Edinburgh, United Kingdom

Ebolaviruses (EBOV) have caused more than 40 outbreaks since its discovery in 1976, with a high case fatality rate of 50-80% per outbreak. A budding mystery in the epidemiology of EBOV is the reactivation of the virus within EVD survivors after a prolonged latency period, a phenomenon responsible for most of the recent outbreaks. However, it is unclear how long this latency period last and whether different bat species, identified as EBOV's reservoir host, experience this latency before the spillover event. To explore these questions, we assembled a genome dataset that spans the known history of EBOV outbreaks from GenBank. Based on bat surveillance in the location where EVD outbreaks have been reported, we identified several candidate bat species that tested positive for EBOV antibody, and we narrowed it down to three that tested positive for EBOV on PCR. Analysis was done by partitioning the genomes into codon regions and assigning each partition an HKY model with gamma-distributed specific rates. We set the bat's species as traits and estimated the latency process using the explicit latency model implemented in BEAST as a molecular clock. All three fruit bats species showed evidence of involvement in the transmission dynamics of the virus. Their pattern of involvement suggested that earlier EBOV outbreaks occurring between 1976 to 2000 originated from central Africa and most likely spilt over from Epomops franquetti. The subsequent epidemics from 2003 to 2021 spilt over from Hypsignathus monstrous and Myonycteris torquata. We used the estimated proportion of the latency across various branches to deduce the virus's diffusion process during quiescent stages in bat populations providing valuable insight into the virus's molecular evolution outside of human hosts. We further predicted the approximate period for the likely resurgence of EBOV in both human and nonhuman hosts, considering if the virus started off from persistent or latent EBOV. This study is crucial for devising timely follow-up strategies for EVD survivors and initiating EBOV surveillance among bat populations.

5296

MOLECULAR PHYLOGENY AND SEROTYPE DISTRIBUTION OF DENGUE VIRUS IN THE PHILIPPINES, 2015-2022

Kristine Joy Ragual Privaldos, Ava Kristy Lee, Joan Bato, Mary Ann Quinones, Carissa May Enriquez, Frances Anne Caranto, Mary Anne Joy Reyes
Research Institute for Tropical Medicine, Alabang, Muntinlupa, Philippines

Dengue is the most prevalent arboviral disease in humans and it has caused tremendous burden to the tropical and sub-tropical countries. In the Philippines, dengue is considered as a major public health problem and is probably the most well-known arboviral infection and feared tropical disease. Despite being endemic in the Philippines with all four Dengue virus (DENV) serotypes, there is a limited information available about the circulating viral serotypes and genotypes. Serum samples (n = 30,594) from dengue suspected patients for the years 2015 to 2022 were sent to the Research Institute for Tropical Medicine (RITM) to detect DENV serotype by Real-time RT-PCR. The E gene was amplified using one-step RT-PCR and followed by direct Sanger sequencing. Phylogenetic analysis was done using Maximum Likelihood and General Time-Reversible +G model with 1,000 replicates for bootstrap (1,500+nt) by MEGA 7.0 for genotype identification of positive DENV samples. Dengue RNA was detected in 15,367 samples, 1,364 of these were successfully sequenced for the whole E gene. The predominant serotypes for 2015 were DENV 1 and 2. Subsequently, a shift to DENV 3 serotype from 2016 to 2019 was observed. However, in the year 2022, DENV 1 and 2 were detected again to be the dominant serotypes. It is also notable that in the same year, DENV 4 detection have increased compared to the previous years. Phylogenetic analysis showed that the Philippine DENV samples existing genotypes were: DENV 1 (GI = 5, GIV = 490), DENV 2 (Cosmopolitan = 292), DENV 3 (GI = 474), and DENV 4 (GII = 103). The eight-year phylogenetic data suggested that the existing genotypes for DENV 1 to DENV 4 in the Philippines originated mostly from Asian countries and French Polynesia. Constant monitoring of circulating strains is vital in understanding the phylodynamic patterns of disease outbreaks. This will aid in the development of future regional vaccines with antigenic and genetic compositions based on the surveillance.

5297

PERSISTENCE OF SERUM IGM ANTIBODIES ANTI-CHIKUNGUNYA VIRUS FOR MORE THAN 24 MONTHS AFTER THE ONSET OF ACUTE SYMPTOMS

Leile Camila Jacob-Nascimento[1], Moyra Machado Portilho[1], Rosangela Oliveira Anjos[1], Patricia Sousa dos Santos Moreira[1], Viviane Machicado[2], Adriane Souza Paz[2], Lorena Gomes[1], Uriel Kitron[3], Scott Weaver[4], Mitermayer Galvão Reis[5], Guilherme Sousa Ribeiro[6]

[1]Oswaldo Cruz Foundation, Salvador, Brazil, [2]Bahiana School of Medicine and Public Health, Salvador, Brazil, [3]Emory University, Atlanta, GA, United States, [4]World Reference Center for Emerging Viruses and Arboviruses, University of Texas Medical Branch, Galveston, TX, United States, [5]Oswaldo Cruz Foundation / Federal University of Bahia / Yale University, Salvador / New Havem, Brazil, [6]Oswaldo Cruz Foundation / Federal University of Bahia, Salvador, Brazil

How long anti-chikungunya virus (CHIKV) IgM antibodies remain detectable in the bloodstream is not well established. Thus, our objective was to assess the frequency of detection of anti-CHIKV IgM antibodies over time using a commercial ELISA (CHIKjjDetect™ IgM ELISA kits; InBios International Inc., Seattle, USA) in 148 serum samples obtained sequentially from 45 patients with CHIKV infection who developed chronic joint pain. Infection was confirmed by qRT-PCR (N=43) or IgM seroconversion (N=2) during an outbreak in Salvador, Brazil, between June 2019 and February 2020. Each patient had a minimum of three and a maximum of six serum samples available for testing. Among the samples obtained within 7 or between 11-30 days post-symptoms onset (DPSO), 13.3% (6/45) and 97.5% (39/40) were positive for anti-CHIKV IgM, respectively. All the samples obtained between 31-60 (N=11), 61-90 (N=9), 91-120 (N=2), or 121-180 (N=5) DPSO were positive for anti-CHIKV IgM. Among 19, 7, and 4 samples obtained between 721-900, 901-1080, or 1081-1260 DPSO, 6 (31.5%), 1 (14.2%), and 1 (25.0%), respectively, remained CHIKV IgM-positive. Considering the 23 patients with at least one serum sample collected >720 DPSO, we found that 7 (30.4%) still had IgM detectable. These results indicate that, in contrast to the typical duration of IgM following acute viral infections of only a few months, a significant proportion of chikungunya patients that develop chronic joint pain can maintain CHIKV IgM detectable for more than two years after acute disease. Thus, the application of CHIKV IgM serological tests for diagnosis of acute illness in settings where large CHIKV epidemics occurred and endemic transmission ensued may be misleading due to detection of antibodies that may represent infections from previous years. This possibility is especially concerning if our findings are also valid for patients that do not develop chronic symptoms. Further studies should verify whether our results hold for patients without chronic symptoms and evaluate whether maintenance of anti-CHIKV IgM antibodies correlates with the duration of arthralgia, which would suggest viral persistence.

5298

CROSS-SECTIONAL EVALUATION OF ANTI-SARS-COV-2 ANTIBODY RESPONSE TO AZD1222 RECOMBINANT VACCINE DEPLOYMENT IN THE BONO REGION, GHANA

Prof Samuel Fosu Gyasi

University of Energy and Natural Resources, Sunyani, Ghana

Preliminary data across the globe shows that the AZD1222 recombinant vaccine was highly effective in preventing not only the symptoms but also the transmission of the SARS-CoV-2 virus. In Ghana, data on the immune response generated by different vaccination doses is lacking. The present study aimed to compare the anti-SARS-CoV-2 antibody response among single and double-vaccinated versus unvaccinated individuals. A case-control design was employed for this study. Seventy-nine participants (35 vaccinated, 44 unvaccinated) were recruited from the Sunyani West Municipality and screened for the presence of SARS-CoV-2 specific IgG and IgM antibodies in plasma samples using a Standard COVID IgG and IgM Combo FIA test. Data analysis was carried out with STATA (Version 21). The current study showed that mean IgG levels among vaccine groups (Group 1: Not vaccinated, Group 2: 1 dose, Group 3: 2 doses) differed significantly ($F_{2, 76}=11.457$, $p<.001$) between Group 1 and Group 3; and between Group 2 and Group 3. Participants in Group 2 and Group 3 were 4.1 and 12.5 times more likely to develop more antibody responses compared to their counterparts in Group 1 respectively.This baseline study demonstrated that in the short term, individuals who received either one or two doses of the AZD1222 recombinant vaccine generated a higher antibody response compared to individuals who did not receive any dose of the vaccine. It remains to be seen how long the generated immune response will last in this population and whether a booster shot could be a useful strategy

5299

TO MODULATE OR NOT TO MODULATE: INCREASING IMMUNOGENICITY AND REDUCING IMMUNE EVASION OF SARS-COV-2 VIA NEXT GENERATION VACCINES

Alexandria Dickson, Andreu Gazquez, Taneesh Makkena, E. Taylor Stone, Elizabeth Geerling, Amelia K. Pinto, James D. Brien

Saint Louis University, St. Louis, MO, United States

Coronaviridae is a notable family of viruses that are responsible for multiple epidemics and pandemics throughout the 20th and 21st centuries. The SARS-CoV-2 pandemic and its generation of subsequent variants have magnified the importance of researching and understanding highly pathogenic emerging viruses and forging the advancement of vaccines to combat future pandemics that are likely to occur. The vaccines developed to combat the SARS-CoV-2 pandemic have significantly reduced the likelihood of hospitalizations and death in vaccinated individuals infected with the virus, however as the virus mutates to create emerging variants that evade prior immunity, the need for a robust and efficacious vaccine is the utmost importance. The type I interferon (IFN) response plays a dichotomous role in mRNA vaccines. Type I IFN has been shown to both inhibit and enhance the mRNA vaccine-driven response. Here we provide data showing our investigation of a type I IFN antagonist on mRNA vaccine immunogenicity and protection. As a model system, we developed an mRNA vaccine that expresses stabilized pre-fusion spike protein of SARS-CoV-2 and a type I interferon antagonist for immune modulation to confer robust immunity and protection against SARS-CoV-2 variants while reducing intra-host viral diversity relative to a vaccine encoding spike protein only. We have generated and validated our mRNA vaccine in vivo, leading to the demonstration of vaccine immunogenicity and protective capacity against SARS-CoV-2. Our results indicate that type I IFN antagonists improve vaccine immunogenicity and protective capacity against lethal challenge in comparison to parental mRNA vaccine (spike only). We intend to investigate the immune-modulated vaccine's ability to alter viral population dynamics using SARS-CoV-2 barcode viruses in vaccinated mice post-infection to understand mechanisms of protection and control. Our findings on mRNA vaccine immunogenicity, vaccine efficacy through ancestral and variant challenges, and their impact on virus population dynamics will lead to advancements in the fields of virology, immunology, and evolutionary biology.

SEROPREVALENCE OF HUMAN CORONAVIRUSES IN PEDIATRIC SAMPLES COLLECTED BEFORE COVID-19 PANDEMIC IN THE PHILIPPINES AND JAPAN

Yusuke Sayama[1], Michiko Okamoto[1], Mayuko Saito[1], Mariko Saito-Obata[1], Raita Tamaki[2], Christine Dahlia Joboco[3], Socorro Lupisan[4], Hitoshi Oshitani[1]

[1]Department of Virology, Tohoku University Graduate School of Medicine, Miyagi, Japan, [2]Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, [3]Biliran Provincial Hospital, Biliran, Philippines, [4]Research Institute for Tropical Medicine, Metro Manila, Philippines

Infections of four seasonal human coronaviruses (HCoVs); 229E, NL63, HKU1, and OC43, are common in children, and COVID-19 infections in

children are generally mild. This feature might be associated with protection conferred by recent seasonal HCoVs infection. This study aimed to determine the seroprevalence of HCoVs and SARS-CoV-2 neutralizing antibodies in children less than 5 years old. A total of 419 (Philippines: 315 and Japan: 104) serum samples collected before COVID-19 pandemic period (2015—2019) were tested for IgG antibodies against four seasonal HCoVs and SARS-CoV-2 using recombinant spike ectodomain proteins by enzyme-linked immunosorbent assay (ELISA). Neutralization antibodies against SARS-CoV-2 (wild-type) were also measured for samples collected in the Philippines that were positive for anti-SARS-CoV-2 IgG. As a result, about 90% of children less than 2 months old in the Philippines had IgG antibodies against four seasonal HCoVs. Then, the antibody prevalence were less than 20-47% between 6-11 months old and reached up to 80% by 2-3 years old. The seroprevalence of SARS-CoV-2 was low at about 3% between 6-11 months old and then reached about 50% at 4 years old. The seroprevalence of NL63, HKU1, and OC43 in samples collected in Japan showed a similar trend, although the seropositivity against 229E stayed low (63%) in those aged 4 years. The median age of children in the Philippines who showed positive for anti-SARS-CoV-2 IgG antibodies were older and had significantly higher IgG antibody titer against four seasonal HCoVs, compared with those negative for SARS-CoV-2 IgG antibodies (age: 2.2 years vs. 0.9 years, $p < 0.0001$, antibody titer in each antigen: 7.7-13.5 vs. 1.3-6.13, $p < 0.0001$). These results suggest some cross-reactivity between SARS-CoV-2 and seasonal HCoVs. However, only one of the 69 reactive samples had a neutralization antibody against SARS-CoV-2. Although there is no neutralization capability in samples positive for anti-SARS-CoV-2 IgG antibodies, there might be some cross-reactive antibodies between SARS-CoV-2 and seasonal HCoVs, which might explain lower severity of COVID-19 infections among children.

ASSESSING THE ROLE OF NON-NEUTRALIZING ANTIBODIES IN ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY OF DENGUE VIRUS INFECTED CELLS

Mitchell J. Waldran[1], Adam T. Waickman[1], Jeffrey Currier[2]
[1]SUNY Upstate Medical University, Syracuse, NY, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue virus (DENV) is endemic in over 100 countries causing widespread morbidity and mortality. 400 million people are infected annually, resulting in 100 million symptomatic cases and at least 40,000 deaths. It has been previously described that antibodies against DENV E protein can cause antibody dependent enhancement during secondary DENV infection, increasing infection. However, there are other potential antigen targets created during DENV infection. Non-structural protein 1 (NS1) is a non-structural protein that is both secreted from and expressed on the surface of DENV infected cells. IgM, IgG, and IgA isotype antibodies against NS1 can be readily detected after DENV infection. Our study aims to determine: the capability of NK cells to clear NS1 expressing cells opsonized by αNS1 antibodies via antibody-dependent cellular cytotoxicity (ADCC), confirm cytotoxic activation of NK cells with opsonized NS1-expressing cells, what receptors are used in both IgG and IgA isotype mediated killing of NS1 expressing cells, and if secreted NS1 functions to protect DENV-infected cells from ADCC. To this end, we will analyze ADCC using a flow cytometry based ADCC assay. We will assess the death of NS1-expressing cells in the presence of NS1-reactive antibodies and NK cells, and we will also assess the activation of NK cells using CD107a as a cytotoxic activation marker on NK cells. We will also assess receptor utilization of NK cells for IgG or IgA mediated ADCC. Using an αCD89 antibody known to block FcαR binding to IgA, we can assess potential reduced ADCC of opsonized NS1-expressing cells with an IgA monoclonal antibody. Similarly, using αCD16, 32, and 64 antibodies known to block FcγRs binding to IgG, we can assess reduced ADCC of opsonized NS1-expressing cells with an IgG monoclonal antibody. We have previously shown that secreted NS1 can block monocytic phagocytosis of NS1-expressing cells. We will also investigate the ability of secreted NS1 to block ADCC by NK cells and NK cells to decrease viral proliferation by killing infected cells.

5302

MODULATION OF COMPLEMENT REGULATORY MOLECULES IN INFECTED AND BYSTANDER CELLS DURING DENGUE VIRUS INFECTION

Maris S. Wilkins, Priscila M. S. Castanha, Ernesto T. A. Marques
University of Pittsburgh, Pittsburgh, PA, United States

Dengue virus (DENV) is a flavivirus with four known circulating serotypes (DENV 1-4). Infection with DENV can result in a wide spectrum of disease: primary infections tend to produce milder disease while secondary infections can be associated with more severe disease, though the mechanisms behind this phenomenon are not well defined. The complement cascade seems to play an important role during DENV infection, as cleaved complement factors such as the anaphylatoxins C3a and C5a have a potent effect on the permeability of the capillary vasculature. Recent studies suggest that complement dysregulation and overactivation may play a role in the development of severe dengue disease. In this study, we aimed to investigate the effect of infection on the expression of complement regulatory molecules on both infected and bystander cells. HepG2 and Bewo cells were infected with DENV-2 16681 (MOI = 1) for 48 and 72 hours post infection (hpi). Cells were then stained with anti-CD55, anti-CD46, and anti-DENV antibodies and analyzed by flow cytometry to determine the expression of CD55 and CD46. Infection with DENV-2 resulted in 13-18% of total cells expressing DENV E protein. During DENV-2 infection, a significant decrease in the expression of complement regulatory molecules CD55 and CD46 was observed at both 48 and 72 hpi in bystander cells, while expression levels in mock-infected and DENV-infected cells remained normal. Our results suggest that DENV-infected cells can augment expression of complement regulatory molecules and prevent cell death. Going forward, we plan to utilize a human skin explant model to investigate the mechanism by which DENV modulates expression of these complement regulatory molecules on infected cells while inhibiting their expression on bystander cells.

5303

THE DIFFERENTIATION OF TREG AND TH17 CELLS IN PATIENTS WITH CHRONIC HEPATITIS B IN DIFFERENT STAGES

Hang TT LE[1], Tien Huy Nguyen[2], Hoa PHAM[1]
[1]University of Medicine and Pharmacy at HCMC, Ho Chi Minh, Viet Nam, [2]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan

Regulatory T (Treg) and T helper 17 (Th17) cells modulate the immune response in chronic hepatitis B virus infection by promoting immune tolerance, restricting liver damage, stimulating inflammatory responses, and inducing hepatocyte injury. These cells act by signaling transcription factors and secreting cytokines. Our study aimed to observe the percentages of Treg and Th17 cells, as well as their mRNA levels of Foxp3 and RORγt, in chronic hepatitis B (CHB)-infected groups and CHB patients experiencing hepatitis flare (HF). We recruited 159 participants, including 137 CHB-infected cases and 22 healthy controls (HC) from Ho Chi Minh City. CHB cases were divided into three groups: HBeAg+ CHB infection (e+CHBI, n=52), HBeAg+ CHB (e+CHB, n=24), and HF (n=61). Treg and Th17 cells were measured by flow cytometry, and the mRNA levels of Foxp3 and RORγt were analyzed by Realtime PCR. The percentages of Treg, Th17, and a special subset - IL17A(+)Foxp3(+)Treg cells - were significantly higher in the HF group compared to the e+CHBI group. Meanwhile, there was no significant difference in the mRNA levels of Foxp3 and RORγt in CHB groups. These findings reveal that these immune cells increase with the severity of the liver injury, and the mRNA levels of transcription factors do not correlate with the percentages of their cells. Our results explain the diversity of T cells and their subsets in the immune response in CHB and suggest that the new subset should be further investigated as a specific tool in the HBV immune response.

5304

INDIRECT IGG ELISA AND SEROTYPE-SPECIFIC NEUTRALIZING ANTIBODY TITERS ARE ASSOCIATED WITH DENGUE IN CHILDREN IN CEBU, PHILIPPINES

Camila D. Odio[1], Jedas Veronica Daag[2], Maria Vinna Crisostomo[2], Kristal-An Agrupis[2], Ava Kristy Sy[3], Cameron Adams[4], Laura J. White[4], Jacqueline Deen[2], Aravinda M. de Silva[4], Leah C. Katzelnick[1], Michelle Ylade[2]

[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines Manila, Manila, Philippines, [3]Department of Virology, Research Institute for Tropical Medicine, Muntinlupa, Philippines, [4]Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States

Standard measures of dengue virus (DENV) antibodies have not been consistently associated with dengue disease. We assess whether an indirect dengue IgG ELISA (PanBio; Brisbane, QLD, Australia), plaque reduction neutralization test (PRNT) to DENV1-4, and preparation of virus used in this assay (standard vs. mature) are associated with dengue risk and protection. Healthy children (n = 1,214) aged 9-14 years in Cebu, Philippines were enrolled in a prospective cohort study in May - June 2017, and febrile illness prompted dengue diagnostic testing through March 2020. At enrollment, all sera were tested for binding antibodies by ELISA, and random subsets were tested for neutralizing antibodies by PRNT to DENV1-4 using WHO reference (standard, n = 737) and mature clinical strains (n = 77). The probability of dengue was modeled as a function of baseline antibodies using logistic regression and generalized additive models adjusted for age, sex, and enrollment site. Inverse probability weighting was used to account for subset size. The probability of symptomatic dengue was 11.1% (95% CI: 5.6-20.9) in the naïve group vs. 3.6% (2.0-6.3) for those with ELISA >= 3 (p = 0.005). By standard PRNT, geometric mean titers to DENV1-4 (GMTs) > 200 were protective (1.4% [0.6-3.1], p<0.0001) with no enhancement at lower GMTs. Baseline standard PRNT titers to DENV2 and DENV3 were protective against a homotypic dengue case (DENV2: OR 0.28, 95% CI 0.12 to 0.65; DENV3: OR 0.27, 95% CI 0.13 to 0.57), but not heterotypic dengue. Among children who entered the cohort with multitypic immunity, none had GMTs < 40 by the standard PRNT, but 49% had GMTs < 40 by the mature PRNT. Using the mature PRNT, GMTs between 40-100 were enhancing compared to GMTs <40 (probability of dengue: 15.4% [8.2-27.1] vs. 7.1% [3.7-13.3], p = 0.024) while GMTs >100 were protective (1.4% [0.3-5.4], p = 0.024). In sum, a commercial ELISA and neutralizing antibodies are associated with dengue. We hypothesize that the mature PRNT has a higher threshold for antibody binding and thus more accurately identifies enhancing and neutralizing antibodies. These assays may be valuable for use in population and vaccine trials.

5305

DETECTION OF ENVELOPE-DIMER EPITOPE-LIKE BROADLY PROTECTIVE ANTIBODIES IN DENGUE-IMMUNE CHILDREN IN THE PHILIPPINES FOLLOWING VACCINATION AND NATURAL INFECTION

Patrick I. Mpingabo[1], Michelle Ylade[2], Maria Vinna Crisostomo[2], Devina Thiono[3], Jedas Veronica Daag[2], Kristal-An Agrupis[2], Ana Coello Escoto[1], Guillermo Raimundi Rodriguez[1], Kelsey E. Lowman[1], Saba Fideous[1], Rosemary A. Aogo[1], Camila Odio[1], Laura White[3], Aravinda de Silva[3], Jacqueline Deen[2], Leah C. Katzelnick[1]

[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, NIAID, NIH, Bethesda, MD, United States, [2]University of Philippine-Manila, Manila, Philippines, [3]Department of Microbiology and Immunology, University of North Carolina Chapel-Hill, Chapel-Hill, NC, United States

The dengue vaccine, Dengvaxia, has been described as inducing antibody-dependent enhancement (ADE) in dengue-naive individuals. There is an urgent need to develop an effective dengue vaccine that elicits protective, cross-reactive neutralizing antibodies (Abs) like envelope-dimer epitope (EDE) Abs, which target quaternary epitopes on the E protein dimer and neutralize dengue viruses 1-4 (DENV1-4) without triggering ADE. Here, we investigated natural infection and vaccine-induced cross-reactive neutralizing Abs in children with prior DENV infection histories in a longitudinal vaccine cohort in Cebu, Philippines. In total, 1,214 children remained unvaccinated while 1,782 children received a single dose of Dengvaxia in June of 2017 during a mass vaccination campaign. Serum samples were collected one month before and one year (12-18 months) after the vaccine campaign. We selected a random subset of n=223 polytypic DENV-immune children to measure baseline status and change in EDE-like Abs due to natural infection and vaccination. Paired samples were tested by Plaque Reduction Neutralization Test (PRNT) with mature DENV1-4 low passage clinical isolates and a Blockade-of-Binding (BOB) assay to detect Abs that prevent EDE Ab C8 from binding a DENV2 E protein dimer. An IgG ELISA against the DENV1-4 E protein monomer and DENV2 E protein dimer were also performed on the same participants for comparison to the mature PRNT and BOB. Both vaccinated and unvaccinated groups had high levels of EDE C8-like Abs at baseline. We also observed a significant increase in Ab level after one year in both groups across all assays. The level of C8-like Abs in a sample was correlated with how well the sera were able to neutralize mature DENV1-4 in PRNT assays. This correlation was stronger in naturally infected sera than vaccinated sera, indicating differences in Ab quality. These results highlight the presence of EDE-like Abs that could possibly protect against the four DENV serotypes and provide insights for future vaccine candidates.

5306

THE MAGNITUDE AND QUALITY OF NEUTRALIZING ANTIBODIES CORRELATE WITH PROTECTION AGAINST SYMPTOMATIC DENGUE VIRUS INFECTION AND DIFFER BY SEROTYPE, IMMUNE STATUS, AND ASSAY CONDITION

Sandra Bos[1], Aaron Graber[1], Elias Duarte[1], Jaime Cardona-Ospina[1], Jose Victor Zambrana[2], Reinaldo Hernandez Mercado[1], Tulika Singh[1], Aravinda de Silva[3], Leah Katzelnick[4], Angel Balmaseda[5], Eva Harris[1]

Neutralizing antibodies (nAbs) are considered an essential component of the protective response against the four serotypes of dengue virus (DENV1-4), yet measurement of their potency is primarily performed using a single cellular substrate and partially mature virions. This does not capture the full breadth of nAb activity and may lead to biased estimations of nAb potency and repertoire. Here, we evaluated the nAb response associated with protection against symptomatic DENV infection using samples collected after one or more DENV infections but prior to a subsequent symptomatic or inapparent DENV1, DENV2 or DENV3 infection in a long-standing pediatric cohort study in Nicaragua. We compared nAb titers in pre-inapparent and pre-symptomatic infection samples measured in Vero cells with or without DC-SIGN expression infected with mature or partially mature virions. This allowed us to measure the magnitude and the quality of the nAb response and revealed that nAb correlates of protection are dependent on the individual's prior DENV immune status (primary vs. secondary) and the infecting serotype. Higher cross-reactive nAb titers were associated with protection against DENV1 and DENV2 disease in participants with one prior infection (DENV1 and DENV2) or multiple prior infections (DENV2), while no difference was observed between the pre-DENV3 infection groups. The nAb potency and the protective NT50 correlate were greatly impacted by virion maturation state and cell substrate. For all serotypes combined, the median NT50 to partially mature virions in Vero cells was 202, compared with 42 to mature virions in Vero-DC-SIGN cells. nAbs to mature virions with Vero

DC-SIGN cells had the lowest threshold (NT50 = 180) for detecting 90% of the individuals with subsequent symptomatic disease and was correlated with protection (Odds Ratio 0.85, 95% Confidence Interval 0.73-0.96), in comparison with partially mature virions and mature virions in Vero cells (threshold NT50 = 898 and 476, respectively). These results have important implications for determination of antibody correlates of protection for vaccines and natural infections.

NEUTRALIZING IGM CONTRIBUTE SUBSTANTIALLY TO BOTH PRIMARY AND SECONDARY DENGUE SEROTYPE 1 IMMUNITY

Tulika Singh[1], Rohan Shinkre[1], Aaron Graber[1], Michael Verdolin[1], Sandra Bos[1], José Victor Zambrana[2], Cesar Narvaez[2], Sonia Arguello[2], Federico Narvaez[3], Angel Balmaseda[4], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Infectious Diseases Unit, Hospital Infantil Manuel de Jesus Rivera, Managua, Nicaragua, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

IgM antibodies can contribute to virus neutralization, but their role in immunity to dengue virus serotypes 1-4 (DENV1-4) remains a gap. DENV1-4 cause ~100 million infections per year, with 25-50% symptomatic cases. Using children's plasma from our long-standing hospital-based study in Nicaragua, we compared DENV-neutralizing IgM antibodies in primary (1º; n=10) and secondary (2º; n=19) DENV1 infections. Plasma from ~14-30 days post-symptom onset were IgM- vs mock-depleted, and polyclonal IgM was eluted. We found that plasma IgM antibodies in both 1º (Mean NT50=0.23µg/mL) and 2º (Mean NT50= 2.6µg/mL) DENV1 cases demonstrated potent neutralizing activity against DENV1, the infecting serotype. Surprisingly, in 55% (10/18) of 2º DENV1 cases, plasma IgM contributed an average of 30% (range 8-76%) of total plasma DENV1-neutralizing activity at early convalescence, which is the peak antibody response. In this subset, mean DENV1-neutralizing titer in plasma with IgM was higher than plasma without IgM (NT50 = 63,831 vs 49,458; $p<0.05$, Wilcoxon paired rank test). Even after controlling for IgG in each fraction, the DENV1-neutralizing titer of plasma with IgM was 21% higher than that without IgM. This demonstrates a substantial role of IgM in 2º DENV1 cases. As a benchmark, plasma IgM from 1º DENV1 cases (n=8/9) contributed to a mean of 54% (24-76%) of total plasma DENV1-neutralizing activity. Additionally, we found that eluted plasma IgM from 2º vs 1° DENV1 cases were phenotypically distinct, with more cross-neutralization of DENV2 and DENV3 in 2° (Mean NT50 DENV2 =3.8; DENV3 = 2.4 µg/mL) compared to 1º (Mean NT50 DENV2 = 4.6; DENV3 = 12 µg/mL) DENV1 cases ($p<0.05$; Mann Whitney Test). Thus, plasma IgM from the early convalescence of both 1º and 2º DENV1 cases demonstrate substantial antiviral activity, and breadth of IgM DENV-neutralization is greater in 2º DENV1 immunity. Contribution of IgM to 2º DENV immunity is particularly intriguing since this is a time at risk for enhanced dengue. Neutralizing IgM may have an underappreciated role in controlling DENV infection.

Yount[1], Sandra Henein[5], Angel Balmaseda[6], Eva Harris[7], Aravinda M. De Silva[5], Ralph S. Baric[1]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, [2]Washington University St. Louis School of Medicine, St. Louis, MO, United States, [3]Molecular Microbiology and Immunology, School of Medicine, St. Louis University, St. Louis, MO, United States, [4]University of Michigan School of Public Health, Ann Arbor, MI, United States, [5]UNC Chapel Hill School of Medicine, Chapel Hill, NC, United States, [6]National Virology Laboratory, National Diagnostic and Reference Center, Managua, Nicaragua, [7]Division of Infections Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

After primary dengue (DENV) infection or vaccination, individuals develop antibodies to different epitopes and domains on the DENV envelope (E) and pre-membrane (prM) glycoproteins. Of these, serotype-specific (TS) antibodies typically target E domains, while serotype cross-reactive (CR) antibodies typically the target pre-membrane (prM) protein and conserved regions of E. Age-dependent vaccine efficacy has been observed in Phase III trials of pediatric live-attenuated vaccination against DENV, where younger children have lower protection after vaccination compared to older children. A possible component of this difference may be variation in epitopes of neutralizing antibodies elicited by maturing immune systems. To identify and quantify E-domain, neutralizing TS antibody responses in polyclonal sera, we developed a panel of chimeric DENV4/2 viruses that incorporate DENV2 envelope domain I, II, and III (DENV4/2-EDI, EDII, EDIII, respectively) into the DENV4 E glycoprotein. The recovery of viable DENV4/2-EDII recombinants was dependent on the inclusion of chimeric DENV4/2 prM protein that maintained critical interactions with chimeric E. The ED-chimeric virions preserved epitopes of TS and envelope dimer epitope (EDE) CR mAbs and had similar sensitivity to CR polyclonal responses as the parental strains. In natural infection and human challenge samples, the neutralizing activity of polyclonal sera predominantly targets EDIII. To evaluate age-based differences in antibody domain-level epitope targets controlling for prior exposure, we also present an analysis of primary DENV2 convalescent sera from the Pediatric Dengue Cohort Study located in Managua, Nicaragua. Additional studies in controlled experimental studies and well-described observational cohorts will examine if ED epitope targets correlate with protection against subsequent infection.

Escoto[1], Cameron Adams[2], Long Ping Victor Tse[3], Michelle Ylade[4], Jedas Veronica Daag[4], Maria Vinna Crisostomo[4], Kristal-An Agrupis[2], Ralph Baric[2], Jaqueline Deen[4], Aravinda de Silva[2], Laura White[2], Leah C. Katzelnick[1]

[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States, [3]Department of Molecular Microbiology and Immunology, Saint Louis University, Saint Louis, MO, United States, [4]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines Manila, Manila, Philippines

Dengue virus seropositivity is often measured by plaque reduction neutralization test (PRNT), which assesses the antibody response of a patient against one or more of the dengue virus serotypes 1-4 (DENV1-4). These tests consist of serum from a patient and an infectious virus, but the high antigenic diversity of dengue virus may mean that the neutralizing capacity of an individuals' serum is variable by strain. Additionally, viruses can emerge from cells at different stages of maturity (defined by the cleavage of the precursor membrane protein), with mature viruses possessing a more homogeneous structure and fewer antibody-accessible epitopes. To assess the effect of these variables on neutralization assays, we grew both standard and mature preparations of highly passaged DENV1-4 WHO reference strains, where lab adaptation may increase antibody cross-reactivity, and low-passage DENV1-4 clinical isolates from Southeast Asia (SEA). All strains were tested with sera from 26 children aged 9-14 participating in a cohort study in Cebu, Philippines with evidence of multiple prior dengue virus infections. As anticipated, antibody titers were

highest against the WHO-standard strains, but surprisingly, we also found that the WHO-mature strains had the lowest titers. When we scrutinized this trend by serotype, the WHO-standard strains consistently had the highest titers, while the titers of the other three virus preparations relative to one another were variable by serotype. Overall, the geometric mean titers of the SEA strains were significantly different from the titers of the WHO strains irrespective of maturation preparation ($p < 0.001$), but the SEA strains were less sensitive to changes in maturity ($p=0.09$) than the WHO strains ($p<0.0001$). Our results suggest that careful consideration should be given before selecting a viral strain for neutralization assays. A mature isolate may be more useful as a correlate of protection. However, for identifying any prior DENV infection, a standard lab-adapted virus may better detect weakly neutralizing antibodies.

Dengue virus (DENV) is an increasingly important human pathogen, with half of the globe living in environments where DENV transmission may one day occur. Since only a minority of infections are captured by direct detection methods (PCR or antigen tests), serological assays play an important role in the diagnostic process. However, interpreting results from serological assays across different platforms remains challenging, particularly because interpretations from multiple assays may differ, creating uncertainty over how to generate finalized interpretations. Here we utilize mixture models, which provide a probabilistic framework to separate data into multiple distinct components, to infer infected vs. uninfected individuals from longitudinal serological samples. We develop a Bayesian mixture model that can jointly model data from multiple serological assays, and that can incorporate information from serum sampled at multiple time points. We fit to 3479 sampled pairs of acute and convalescent serum collected as a part of illness and household investigations across three longitudinal cohort studies in Kamphaeng Phet, Thailand which contained 298 from gold standard PCR confirmed infections. We compare the classification of the new model to prior standard interpretations that independently utilize information from either the hemagglutination inhibition assay (HAI) or enzyme-linked immunosorbent assay (ELISA). Our results provide a probabilistic framework through which multiple serological assays across different platforms can be combined across sequential serum samples to provide insight into whether individuals have recently experienced DENV. As the differences in results across these platforms reflect performance as well as biological differences, future work will explore the clinical and immunological differences that shape these heterogeneous immune responses to DENV and whether distinct phenotypes may shape subsequent clinical outcomes.

CIRCULATORY T FOLLICULAR HELPER CELL AND MEMORY B CELL FREQUENCIES IN A CONVALESCENT DENV IMMUNE COHORT

Paola N. Flores-Pérez[1], Dorca E. Marcano-Jiménez[1], Rachel Rodriguez[1], Marcos J. Ramos-Benítez[1], William Messer[2], Vanessa Rivera-Amill[1]

[1]Ponce Health Sciences University, Ponce, PR, United States, [2]Oregon Health & Science University, Portland, OR, United States

Dengue virus (DENV) is the cause of the most prevalent mosquito-borne viral disease worldwide, with an estimated 400 million cases and 21,000 deaths per year. Circulatory T follicular helper cells (cTfh) activation, a CD4+ T cell subset that helps B cells, requires antigen presentation through specific human leukocyte antigen (HLA). In some populations, HLA alleles are associated with DENV protection, with robust and multifunctional T-cell responses, supporting a role for T-cells during DENV infection mediated through individual HLA alleles. However, studies identifying conserved HLA alleles specific to DENV epitopes and HLA-restricted T cells (DENV-specific HLA-restricted T cells) across multiple DENV endemic populations, including Puerto Rico, still need to be included. In this context, we aim to characterize the breadth and magnitude of DENV-specific HLA-restricted cTfh cell responses in a convalescent DENV immune cohort to access specific cellular and host genetic factors mediating the adaptive immune response to DENV infection. Here we test the hypothesis that DENV-specific HLA-restricted cTfh cells persist over the convalescent period with heightened breadth and magnitude. HLA class II alleles from stored buccal samples will be genotyped by Next-Generation Sequencing using the MHC Core Library Prep and Capture Kit. We aim to describe the HLA alleles from a Puerto Rico cohort. The HLA alleles selected for the study will be the most frequent alleles worldwide for each locus and the unique alleles in the population. The investigators anticipate that DENV-specific HLA-restricted cTfh cells circulating in blood persist over convalescent infection with heightened breadth and magnitude.

MALARIA ABOLISHES ONNV-INDUCED ARTHRITIS BY ALTERING THE KINETICS OF VIRUS-SPECIFIC CD4 T CELL DEVELOPMENT IN THE FOOTPAD-DRAINING LYMPH NODES

Anthony Torres-Ruesta, Teck-Hui Teo, Yi-Hao Chan, Siti Naqiah Amrun, Siew-Wai Fong, Fok-Moon Lum, Laurent Renia, Lisa Ng

*A*STAR Infectious Diseases Labs, Singapore, Singapore*

O'nyongnyong virus (ONNV) is a re-emerging Alphavirus known to be transmitted by main malaria vectors, suggesting the possibility of co-infections with Plasmodium species in areas of co-transmission. However, the immunopathological consequences of such infections remain unexplored. Using experimental murine co-infection models, we demonstrated that a pre-existing blood-stage Plasmodium infection abolishes ONNV-induced footpad swelling by suppressing the infiltration pathogenic CD4 T cells into the footpads of co-infected mice. T cell profiling of footpad-draining lymph nodes (LN) upon ONNV inoculation revealed altered expansion of swelling-driving CD4 T cells but not CD8 T cells. Assessment of LN migratory dendritic cells (mDC) in co-infected mice revealed impaired mDC numbers and activation capacity which was restored upon blockade of Plasmodium-induced interferon gamma (IFNg) and restitution of viral antigen availability in the footpads. However, the restoration of mDC numbers and, consequently, CD4 T cell expansion in footpad-draining LN of co-infected animals did not restore footpad swelling suggesting an IFNg-independent mechanism. Importantly, lymph nodes from malaric mice displayed increased numbers of PD-1+ICOS+ and TFH-like CD4 T cells during the first 72 hours post-ONNV inoculation which correlated with the induction of germinal center (GC) responses in footpad-draining lymph nodes. These preliminary data suggest that the suppression of ONNV-induced footpad swelling during murine malaria could be linked to the shifting of virus-specific T cell responses towards a TFH-like phenotype.

Additional experiments aiming at identifying soluble immune factors that could explain the development of TFH responses in in footpad-draining LN of co-infected mice are being carried out.

5313

EVALUATING THE CONTRIBUTION OF NS1 ANTIGENEMIA TO DENGUE-ELICITED NEUTROPENIA

Chad Gebo, Mitchell Waldran, Lauren Bahr, Adam Wegman, Nathan Roy, Adam Waickman

SUNY Upstate Medical University, Syracuse, NY, United States

Neutrophils are an important part of the innate immune response and host protection from invading pathogens. One way pathogens try to impede this innate response is decreasing the number of neutrophils available, causing neutropenia. Neutropenia is a common clinical manifestation in viral infections, including dengue infection. Dengue virus (DENV) is responsible for dengue disease, a tropical disease responsible for an estimated 400 million infections per year and significant healthcare burden. The cause of dengue-elicited neutropenia is unknown but is an important question in the field due to culpability of activated neutrophils and their byproducts in the risk of hemorrhage in severe dengue. Neutropenia has a variety of causes, one prospect in the context of dengue infection is a cell death pathway known as NETosis. The cell releases its nuclear content complexed with antimicrobial proteins to immobilize invading pathogens; evidence of this process has been found during dengue infection. Using data collected from the Dengue Human Infection Model challenge study, our lab analyzed the early viral kinetics of dengue infection and identified the secreted form of DENV non-structural protein 1 (sNS1) in serum as a potential contributor to neutropenia. sNS1 plays an important role in dengue pathogenesis and is implicated in disrupting endothelial cell monolayer integrity and platelet activation, both important components of vascular destabilization during severe disease through interaction with TLR4. TLR4 engagement can induce NETosis, providing a potential link between sNS1 and neutrophils. To test sNS1 involvement in NETosis, we stimulated isolated neutrophils with vary concentrations of NS1 for three hours. Using fluorescent microscopy, we found that sNS1 appears to trigger cell death in neutrophils. We plan to preincubate neutrophils with a TLR4 blocking antibody to determine if TLR4 mediates sNS1 induction of neutrophil death. This begins to address the question of whether secreted NS1 interaction with neutrophils plays an important role in mediating dengue-elicited neutropenia through triggering of cell death pathways.

ARBOVIRUS TRANSMISSION AND DISEASE PATHOGENESIS IN OBESE AND TYPE II DIABETIC MICE

Natalia I. Oliveira Silva[1], Sasha R. Azar[2], Vidyleison N. Camargos[1], Rumei Yun[1], Jiehua Zhou[1], Rafael K. Campos[1], Alice F. Versiani[1], Shannan L. Rossi[1], Nikos Vasilakis[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Houston Methodist Research Institute, Houston, TX, United States

In the last century, anthropogenic factors such as human movement to new ecotypes, agricultural expansion, and uncontrolled urbanization, have significantly contributed to zoonotic emergence and spillover at a global scale. Arthropod-borne viruses (arboviruses), maintained in nature through transmission cycles involving hematophagous arthropod vectors, are the most important contributors to disease and a public health concern worldwide. Concomitantly, another contemporary public health concern is the prevalence of chronic underlying conditions. According to the World Health Organization (WHO), chronic diseases kill approximately 41 million people each year, with cardiovascular disease, cancer, respiratory diseases, and diabetes accounting for the most deaths. Strikingly, clinical data indicate that patients with preexisting conditions such as diabetes infected with mosquito-borne viruses are prone to severe disease outcomes and mortality. It is reasonable to hypothesize that such conditions will impact the progression of arboviral replication and transmission in and from human hosts. In the present study, we aim to understand the arbovirus disease pathogenesis, viral kinetics, and mosquito acquisition of arboviruses in infected mice suffering from an obese state approximating a Type II diabetes mellitus (T2DM) phenotype. 10-week-old LEPRDB/DB, LEPRWT/DB, wild type C57BL/6J mice were pretreated with IFNAR blockading antibodies to render them permissive to MAYV infection through Aedes aegypti bite. No significant difference in viral load was observed during early infection (3 to 5 days post-infection) by MAYV among the three genotypes (media ranging from 2.1 log10 to 3.1 log10 FFU/mL). This lack of significant difference in the viral load suggests that further histopathological and cytokine analysis must be conducted to analyze if there are differences in the MAYV infection outcome related to TSDM and the wild-type genotypes.

5315

EXPLORING MICRORNA AS POTENTIAL DIAGNOSTIC BIOMARKER FOR ZIKA VIRUS INFECTION

Krishnamurthy Konduru, Santanu Biswas, Krishnakumar Devadas, Indira Hewlett, Maria Rios

US Food and Drug Administration (FDA), Silver Spring, MD, United States

Zika virus (ZIKV) has emerged as a serious public health concern, which accurate diagnosis is of crucial importance, since it impacts pregnancy outcome and has lifelong consequences for newborns from infected mothers. However, current diagnostic tests are challenging for nucleic acid testing due to short-lived viremia and low viral loads, and for serological testing due to antibody cross-reactivity with other flaviviruses leading to misdiagnosis. This study aimed to identify and evaluate microRNAs (miRNAs) in plasma as biomarkers for accurate ZIKV diagnosis. In the discovery phase miRNA profiles were determined by Next-Generation sequencing using plasma samples from pre- and post-seroconversion phase of ZIKV infection, and from non-infected subjects as a control group. Analysis of miRNA results from the discovery phase led to the identification of 110 differentially expressed miRNAs (68 up- and 42 down-regulated) in ZIKV-infected subjects as compared to the control group. We selected 20 miRNAs with high levels of differential magnitude (up or down modulation) between ZIKV-infected and control groups for further evaluation and validation by qRT-PCR using sample from 72 subjects, including 48 ZIKV-infected (26 pre- and 22 post-seroconversion) and 24 from non-infected controls. A total of 5 miRNAs (miR-3929, miR-3615, miR-17-3p, miR-497-5p, and miR-1224-5p) exhibited the highest differential expression to discriminate ZIKV-infected from control, from which 2 (miR-3929 and miR-3615) were identified using the logit model as a signature-panel to distinguish infected from non-infected subjects. To verify and validate the identified signature-panel we performed blind-coded testing in a cohort of 36 plasma samples composed of ZIKV-infected pre- (n=12) and post-seroconversion (n=12) and non-infected control (n=12). Decoded analysis of results revealed that 19/24 infected samples and all uninfected were correctly identified, demonstrating feasibility of the miRNA signature-panel to be used as non-viral and non-immune biomarkers to diagnose ZIKV infection and potentially for monitoring pregnant women in endemic areas.

5316

CARDIAC ELECTROMECHANICAL ALTERATIONS DURING CHIKUNGUNYA VIRUS INFECTION

Elizabeth M. Traverse, Kelli Barr

University of South Florida, Tampa, FL, United States

Chikungunya virus (CHIKV) is a re-emerging arbovirus that is endemic to several parts of the world, including Africa, Asia, South America, and Central America. CHIKV has been shown to infect several tissue systems, resulting in a spectrum of symptoms. While it is generally considered an abnormal presentation, there is significant clinical evidence of CHIKV infection of human cardiac tissues, including myocarditis, arrythmia, and cardiac arrest. These reports span over five decades and include all lineages that were and are currently circulating in the world. As climate change increases the range of CHIKV and more people are at risk of infection, there is a need to understand how CHIKV can affect the heart. In this study, six lines of human pluripotent stem cell derived cardiomyocytes

(hiPSC-CMs) were infected with seven different strains of CHIKV, including field strains of East Central South African, Indian Ocean, Asian, and West African lineages. Microelectrode Array (MEA) was used to assess electromechanical alterations of the cardiomyocytes, including beat rhythm, conduction, and contractility changes. All strains of CHIKV directly infected hiPSC-CMs within two days of infection. MEA analysis revealed differences between impact of CHIKV infection on female hiPSC-CMs and specific CHIKV strains. Multiple linear regression analysis showed that gender was a significant predictor for several electromechanical factors. Statistical analysis did not indicate that any CHIKV lineage caused significant electrophysiological changes. The data show significant changes in electrophysiology of CHIKV infected hiPSC-CMs, where specific CHIKV lineage does not appear to play a role, which is supported by previous clinical data. Further, the experiments conducted here support past mouse model work and reveal hiPSC-CMs as a relevant study model for CHIKV infection of the human heart, allowing for novel discoveries to be made.

5317

SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR AS PROGNOSTIC BIOMARKER FOR SEVERE DENGUE IN ADULTS

Andrew Teo[1], Po Ying Chia[2], Tsin Wen Yeo[1]

[1]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, [2]National Centre for Infectious Diseases, Singapore, Singapore

Dengue is the most common arboviral disease with an estimated 100 million symptomatic infections annually, and cases is expected to increase with warmer climate. Dengue associated illness requiring hospitalization is estimated at 19.0% in Asia, which may strain healthcare facilities during outbreaks. Current biomarkers are inconsistent in predicting SD in early disease, and a combination of biomarkers to predict SD are less feasible in resource limited settings. Together, poses a challenge in the management of dengue patients. In a longitudinal cohort (febrile, critical and recovery phases) of adult dengue patients recruited in Singapore (2016-1019), we evaluated on the utility of soluble urokinase plasminogen activator receptor (suPAR) as a prognostic biomarker of SD. A total 129 patients: 40 dengue fever (DF), 46 dengue warning signs (DWS), 13 SD and 30 controls, were assayed for plasma suPAR levels by ELISA. In the febrile, critical and recovery phases, suPAR levels were significantly elevated in the dengue group compared with controls, and levels were significantly raised with increasing severity (all, P<0.001). By pairwise comparisons, suPAR concentrations were significantly raised in SD versus either DWS or DF in all disease phases, but no significant difference between the DWS and DF groups was observed. By logistic regression, a unit increase in suPAR level was associated with an increased risk of SD in the febrile phase [OR: 2.1, 95%CI (1.2-3.7), P = 0.009] and critical phase [OR: 1.70, 95%CI (1.27-2.28), P < 0.001]. In the febrile and critical phases, the AUROC for suPAR to predict SD was 0.82 (95%CI 0.63-0.99) and 0.86 (95%CI 0.75-0.97), respectively. Using a cut-off, suPAR levels at >4ng/ml, to predict SD, the sensitivity was 86.0% with a specificity of 69.0% in the febrile phase, and 91.0% sensitive and 68.0% specific in the critical phase. The PPV for SD in febrile and critical phases were 35.0% and 42.0%, respectively, and the corresponding NPV was 97.0% (febrile) and 98.0% (critical). In conclusion, plasma suPAR levels were elevated in adult dengue patients in proportion to disease severity and maybe a reliable predictor of SD.

5318

ATTENUATED CHIKUNGUNYA VIRUS STRAIN 181 CLONE 25 INFECTION IN IMMUNOSUPPRESSED RHESUS MACAQUES

Piyanate Sunyakumthorn, Manutsanun Inthawong, Rawiwan Im-erbsin, Sujitra Tayamun, Kesara Chumpolkulwong, Phakorn Wilaisri, Taweewun Hunsawong, Chonticha Klungthong, Stefan Fernandez, Erin E. Ball, Kelly Richard

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Chikungunya is a mosquito-borne infection caused by Chikungunya virus (CHIKV) which is transmitted to humans by the bite of infected mosquitos. CHIKV is a rapid-onset febrile disease characterized by fever, headache, lethargy, arthralgia, muscle pain, and rash. The attenuated CHIKV 181/clone 25 was developed for live vaccine production for human use in 1986 using CHIKV 15561 strain isolated from an infected patient from Thailand. CHIKV 181/clone 25 induced great protection against challenge and highest antibody titers in weanling mice and monkeys; however, it was withdrawn because 8% of volunteers in Phase II human clinical trials developed transient arthralgia. In this study, we studied the ability of attenuated CHIKV strain 181/25 to cause disease in immunosuppressed rhesus macaques (RM) using cyclophosphamide and dexamethasone. The immunosuppressed monkeys were inoculated with 107 PFU of CHIKV strain 181/25. After the infection, all animals exhibited asymptomatic infection as evidenced by lacking of core temperature change, joint swelling and/or lymph node enlargement. No critical changes in blood cell counts were observed following the infection. Viral RNA was detectable in the circulation from day 1 after intravenous infection, and longer bacteremia period was observed in an animal in the immunosuppressed group. Anti-CHIKV IgM and IgG were induced by day 4 post infection. CHIKV-specific cellular immune responses were determined by IFN-γ ELISpot assay and showed the cellular responses during 7 to 14 days post infection. Cytokine profiling was different between the immunosuppressed and control groups. Viral RNA dissemination was found predominantly in lymph nodes and spleen with greater level in the immunosuppressed group. Infectious virus was detected after 1 to 2 days post infection in one animal in each group at relative low level. This study provided laboratory tools to evaluate CHIKV rhesus model for pre-clinical study or drug and vaccine testing. However, to establish symptomatic CHIKV illness, longer immunosuppression treatment may require.

5319

A MACHINE LEARNING AIDED COMPARISON OF LIVER PATHOLOGY AMONG FILOVIRUSES

Christopher Paul Morris, Yanling Liu, Donna L. Perry, David Liu, Jeffrey Solomon, Winston T. Chu, Amanda Hischak, Randy Hart, Kelly Wetzel, John G. Bernbaum, Ian Crozier

NIH, Frederick, MD, United States

Ebolavirus and Marburg virus are filoviruses known for causing hemorrhagic fever. Pathologic changes in the liver are abundant and develop early after infection. However, model specific differences in liver pathology are poorly understood. We performed a retrospective study of the liver pathology resulting from different filoviral models, using machine learning approaches, to investigate model specific differences. Liver slides and blocks were examined from rhesus monkeys infected with Ebola virus (EBOV Kikwit and EBOV Makona), and Marburg virus (MARV), and compared to clinical chemistries obtained during the experiment. All samples were from previous experiments on animals that did not receive treatment or vaccination and were infected intramuscularly with similar inoculant. A board-certified pathologist annotated slides for areas of parenchyma and necrosis in QuPath. Model training was done using a customized multi-class U-Net implemented in Tensorflow. Clinical chemistries showed higher levels of the liver enzyme ALT in animals ifected with MARV (mean 1411) compared to EBOV Makona (mean 666, p= 0.001) or EBOV Kikwit (mean 387, p=<0.001), but lowest levels of AST in animals infected with MARV compared to EBOV Makona or EBOV Kikwit. The percentage of parenchymal area with necrosis was highest in animals infected with MARV

(Mean 35.6%) compared to EBOV Makona (mean=1.7%, p=0.008), or EBOV Kikwit (mean=0.7%, p=0.0013). ALT values and percent necrosis trended higher in EBOV Makona compared to EBOV Kikwit without reaching statistical significance (p=0.08, p=0.08). Linear regression showed a significant association between ALT levels and percent necrosis (p=0.003), but an overall poor fit (R squared=0.34). Histopathologic review of liver samples revealed viral specific differences in presentation between tissues from MARV infected animals compared to EBOV infected animals. No statistical difference was seen between EBOV Kikwit and EBOV Makona. This initial machine learning model development has shown promising results for automated whole slide liver tissue segmentation to provide quantitative data.

Detrick, MD, United States, [4]Washington University School of Medicine, Saint Louis, MO, United States, [5]Oregon Health and Science University, Portland, OR, United States, [6]University of Minnesota, St. Paul, MN, United States

The 2016 Zika virus (ZIKV) outbreak in the Americas revealed a previously unidentified risk of birth defects in babies born to mothers infected with Asian-lineage ZIKV during pregnancy. However, the impact of African-lineage ZIKV infection during pregnancy remains less understood, despite probable origination in Africa and its presumed endemic presence in many countries for decades. Nonhuman primates serve as a valuable model for studying ZIKV in pregnancy due to their gestational similarities to humans and susceptibility to ZIKV infection but limited animal numbers and inconsistent outcomes have hindered the study of ZIKV preventives and therapeutics using this model. While examining the effects of African ZIKV co-infection on pregnancy outcomes in SIV-positive rhesus macaques, we identified a specific combination of infection timing, dose, and ZIKV strain that consistently resulted in fetal demise. Regardless of SIV co-infection or antiretroviral therapy (ART) treatment, 11 out of 14 pregnancies (78%) ended in spontaneous loss within 3 weeks following infection at approximately 30 days gestation with an African-lineage ZIKV. ZIKV was detected in the placentas and fetal tissues in all cases of pregnancy loss. Due to the high rate of pregnancy loss among all ZIKV-infected dams, we could not assess the impact of SIV co-infection. However, we serendipitously developed a model with a consistent outcome necessary for testing medical countermeasures in pregnancy and potentially uncovered an under-appreciated risk of early pregnancy loss due to infection with African-lineage ZIKV.

5321

GENETIC ANCESTRY DRIVES DIFFERENCES IN THE IMMUNE RESPONSE TO DENGUE VIRUS INFECTION IN HUMAN SKIN

Priscila M. Da Silva Castanha, Michelle Marti, Jocelyn Taddonio, Megan Wallace, Gwenddolen Kettenburg, Simon C. Watkins, Ernesto T A Marques Jr., Jeremy Martinson, Simon M. Barratt-Boyes

University of Pittsburgh, Pittsburgh, PA, United States

Epidemiological evidence supports a protective effect of African ancestry against severe dengue, but the mechanisms underlying the effects of ancestry on dengue virus (DENV) infection are unknown. We used full-thickness human skin explants from healthy individuals to define the effects of genetic ancestry on the immune response to DENV infection. We performed genotyping of a set of ancestry informative markers to estimate the proportion of European and African ancestry for each individual. Skin explants were inoculated with DENV-2 using a bifurcated needle and analyzed by confocal microscopy using antibodies to NS3 protein, cell-specific, and inflammatory/ antiviral markers. We found a strong positive correlation between European ancestry and the extent of DENV replication in the epidermis and dermis, which contained two times more infected cells than African ancestry skin. In European skin, increased replication of DENV was mediated by boosted recruitment and infection of macrophages, dermal dendritic cells, and Langerhans cells. Quantitative in situ imaging, as determined by the expression of IL-1β and IFN-α, revealed a robust inflammatory response to DENV infection in European skin, whereas a strong antiviral response was observed in African skin. Simultaneous blockage of IL-1β and addition of IFN-α using microneedle arrays before DENV inoculation inhibited DENV replication by preventing recruitment and infection of myeloid cells in the dermis of European skin. RNA-sequencing of full skin biopsies revealed ancestry-associated differences in the transcriptional response to DENV and confirmed a stronger inflammatory response to infection with increased European ancestry. Profiling of single nucleotide polymorphisms of innate immune-related genes identified several genotype variants (e.g., RXRA, OSBPL10) with higher expression in Africans that were markedly associated with reduced DENV replication in the dermis. Our findings reveal ancestry-related differences in the immune response to DENV infection and identify potential therapeutic targets that could prevent dengue dissemination in human skin.

HCV LEADING EARLY AGE ONSET OF HCC - MULTIPLE RISK FACTORS ATTRIBUTE

Sarthak Gaur, Avneet Kumar Gupta, Dr Prasan Kumar Panda, Gaurav Karna

AIIMS RISHIKESH, Rishikesh, India

HCC development in young adults is multifactorial such as alcohol abuse, HCV, HBV infection, cirrhosis of liver, alcohol consumption, smoking, obesity , genetic and metabolic conditions. Here we report an unusual case of a 27-years-old man who presented with complain of vague right upper quadrant abdominal fullness, jaundice, non-bilious non-projectile vomiting, loss of appetite, and significant weight loss for 2-months. On examination, tenderness + in right hypochondrium , bilateral pedal edema . Patient had elevated liver enzymes (Sgpt-181, Sgot-150) with increased alpha-fetoprotein (16271). Other abnormality include urea-323, creat-9.21, USG was suggestive of chronic kidney disease (contracted kidney with lost CMD). Triple phase CT of abdomen showed a liver mass with arterial enhancement and delayed washout suggestive of HCC and cirrhosis. Patient was diagnosed as HCC at an early stage, which allowed for timely initiation of treatment. This early age onset of HCC in a young adult may be multifactorial such as HCV infection, alcoholism, cirrhosis, smoking, and CKD . Alcohol-induced liver injury increases the risk of developing HCC in persons infected with HCV, with higher risk among those who consume

alcohol heavily. The possible mechanisms of CKD causing HCC involve uremia itself, long-term dialysis status, and miscellaneous factors such as hormone alterations and dysbiosis.

5323

RECONSTITUTION OF HUMAN MICROGLIAL CELLS IN BRAIN CEREBRAL CORTEX AND CEREBELLUM OF HUMAN-IMMUNE-SYSTEM HUMANIZED DRAGA MICE

Sounak Ghosh Roy[1], Ahmad Faisal Karim[1], Teodor-D. Brumeanu[2], Sofia A. Casares[1]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Human microglial cells are a target and reservoir for human pathogens affecting the central nervous system such as HIV, SARS-CoV-2, and Zika virus leading to severe neuropathology in humans. The lack of animal models able to reconstitute human microglial cells poses a challenge for investigating human neuropathology after infection and for testing efficacy of immunotherapeutics. The humanized DRAGA mouse (HLA-A2.HLA-DR4. Rag1KO.IL2RγcKO.NOD) reconstitutes a functional human-immune-system (HIS) upon infusion with CD34+ hematopoietic stem cells (HSC) from HLA-matched human umbilical cord blood. Pluripotent HSCs infused into DRAGA mice migrate in various tissues where they can differentiate not only into hematopoietic-derived cells, but also into non-hematopoietic cells such as human epithelial/endothelial cells expressing the human angiotensin-converting enzyme 2 (hACE2), the primary receptor for the SARS-CoV-2 virus infection, as well as human hepatocytes. The DRAGA mouse, by virtue of reconstituting human cells and by eliciting specific human cellular and antibody responses following infection and vaccination, represents a surrogate "in vivo human model" able to sustain infection with human pathogens such as SARS-CoV-2, Influenza, P. falciparum, HIV, Zika virus, and dengue. Herein we show reconstitution of human microglial cells (hCD45+hCD18+) in the brain cerebral cortex and cerebellum of DRAGA mice by flow cytometry (FACS), with cell numbers averaging 6.3% of the total brain microglia. Immunofluorescence studies further indicated that the human microglial cells in the brain of DRAGA mice were organized in small patches in the cerebral cortex and cerebellum but absent in the control (non-HSC infused DRAGA) mice. The DRAGA mouse model thus represents a novel pre-clinical model to investigate infection and immunopathology of human pathogens targeting human microglia, and for testing the efficacy of novel vaccines and immunotherapeutics.

EFFICACY OF HUMAN SERA FROM SUBJECTS VACCINATED WITH A CHIKUNGUNYA VIRUS VIRUS-LIKE PARTICLE VACCINE IN CYNOMOLGUS MACAQUES

Ravi Anantha[1], Jason E. Comer[2], Lo Vang[1], Christopher S. Morello[1], Kelly Warfield[1]

[1]Emergent BioSolutions, Gaithersburg, MD, United States, [2]University of Texas Medical Branch, Galveston, TX, United States

Chikungunya virus (CHIKV) causes acute illness characterized by fever, fatigue, and severe joint pain, which can lead to debilitating chronic manifestations including arthralgia. Emergent BioSolutions is developing a CHIKV virus-like particle (VLP) vaccine that has demonstrated a robust immune response in nonclinical and Phase 1 and 2 clinical studies. The vaccine has demonstrated protection against viremia after a virulent challenge in non-human primates. To determine the protective efficacy of antibodies induced in humans by the CHIKV VLP vaccine, sera from vaccinated volunteers was used to passively immunize cynomolgus macaques (NHPs). Four dose levels of CHIKV immune sera pooled from subjects who had been vaccinated once with 40 µg of CHIKV VLP vaccine were administered intravenously to six NHPs per group, and an additional six NHPs received negative control sera. All NHPs were challenged subcutaneously at 24 hours with a rescued clone of CHIKV outbreak strain LR2006-OPY1, a strain heterologous to the Senegal strain used to derive the CHIKV VLP. Animals were monitored for ten days following challenge. Analysis of serum immediately before challenge demonstrated that CHIKV serum neutralizing antibody (SNA) levels in NHPs increased in a dose-dependent manner. No animals that were administered CHIKV sera developed viremia at any time during the course of the study, while all animals that were administered control sera developed viremia that peaked two days post-challenge and resolved by day 4 post-challenge. Viral RNA was detected by quantitative reverse-transcriptase PCR in all control animals and in some animals in the two groups that were administered the two lowest dose levels (0.3 and 0.6 mL/kg) of CHIKV sera. No CHIKV RNA was detected in any animals that were administered the two higher CHIKV sera dose levels (1.2 and 2.4 mL/kg) or that had a pre-challenge SNA titer ≥ 25.7. This study demonstrated that sera from vaccinated individuals was sufficient to protect NHPs from viremia and the presence of viral RNA following heterologous CHIKV challenge and that an SNA titer of 25.7 was associated with that protection.

5325

INVESTIGATION OF A SUSPECTED CASE OF MONKEY POX, IBOKE, HEALTH DISTRICT OF TABOU, CÔTE D'IVOIRE, JULY 2022

Kalifa Coulibaly[1], Sabine Lasm[2], Joseph Blaise Otshudiandjeka[3], Wilnique Pierre[3], Issaka Tiembre[1], Vroh Joseph Beni Bi[4]

[1]FETP, Abidjan, Côte D'Ivoire, [2]INSP, Abidjan, Côte D'Ivoire, [3]AFENET, Abidjan, Côte D'Ivoire, [4]INHP/MOH, Abidjan, Côte D'Ivoire

Monkeypox is a global public health problem. In West Africa more than 35 cases have been reported to WHO. On July 30, 2022, the health district of Tabou was informed by the detection of a suspected case of monkeypox in Iboké, a health area bordering Liberia, a country to which a confirmed case of monkeypox was reported. An investigation was carried out with the aim of describing the case, searching for other cases and proposing prevention and control measures. A cross-sectional descriptive study was conducted. A case was defined as any person presenting with an acute rash & one or more of the following signs or symptoms headache, fever, lymphadenopathy, myalgia, body aches, asthenia. The data were taken from consultation registers, interviews with identified contacts. Sociodemographic and clinical characteristics were collected. The data were analyzed in Excel & frequencies measures were calculated. 35-year-old young man with disseminated rashes on the face & the rest of the body accompanied by fever, with no notion of travel outside Iboké but having been in contact with a confirmed case. The result of his sample was negative. Ten (10) contacts were identified without signs & symptoms, of which 8(80%) linked to the suspected case and 2(20%) linked to the confirmed case in Liberia. 80% of the contacts of the suspected case live in Iboké versus 50% (1/2) for the confirmed case. The median age of contacts is 28.5 (range: 5 - 43). The sex ratio is 1.7 male to 1 female. Young man had contact with the confirmed case from Liberia. The majority of contacts lives in Cote d'Ivoire. No case of monkeypox has been detected in Cote d'Ivoire so far. Case management has been recalled and measures have been taken to strengthen cross-border surveillance between the two countries.

SYLVATIC STRAINS OF DENGUE VIRUS HAVE DISTINCT REPLICATION KINETICS IN HUMAN CELLS

Arturo Barbachano-Guerrero, Sara L. Sawyer

University of Colorado, Boulder, Boulder, CO, United States

Dengue disease is caused by each of the 4 types of dengue virus, infecting an estimated 390 million people each year and causing significant morbidity and economic burden. These viruses are endemic in tropical areas of the planet where the competent mosquito vector is available. Dengue viruses are thought to have emerged as a spillover from the dengue sylvatic cycle, where the virus is transmitted among non-human primates in Southeast Asia and Africa. Based on phylogenetic analyses, 4 independent spillover events resulted in the successful generation of the dengue virus types that

circulate in humans today. Other contemporary infections of humans with sylvatic strains have been reported, however, these have resulted in dead-end transmission chains without the generation of a new clade of viruses circulating in humans. What restricts most sylvatic strains of dengue virus to gain efficient transmission in humans remains unknown. Other scientific groups have generated conflicting data on the possible differences among the virus clades. To approach this question, we decided to use a set of complimentary methods to identify differences in replication of lab adapted, clinical isolates, and sylvatic strains of dengue viruses, using human cells as a model. Our data shows that clinical strains of dengue can initiate a complete replication cycle in primary human macrophages, although reaching lower infectious titers compared to lab adapted strains. Among the tested sylvatic strains, all presented lower infectious titers compared to the clinical isolates. As expected, all strains replicated to similar levels in mosquito cells. Currently, we are increasing the number of isolates from clinical and sylvatic origin to better understand inter-strain variability. This research will help understand what regulates the success of spillover events in flavivirus and help to anticipate if risk remains of new clades of dengue viruses entering the human transmission cycle.

5327

SEVERE DENGUE RISK: SPECIAL POPULATIONS WITH REPEATED HIGH-RISK EXPOSURES: CHARACTERISTICS AND A FRAMEWORK FOR RECOMMENDATIONS

Amber F. Britt, Martial Ndeffo-Mbah, Angela Clendenin, Patrick Tarwater, Rebecca Fischer

Texas A&M, College Station, TX, United States

As a re-emerging tropical disease, a growing body of literature has been dedicated to the emergence of Dengue serotypes throughout the world, an increase in the vector range and seasonality, the discovery of dengue in previously unaffected populations and locations, and characteristics that place individuals at greater risk for severe dengue—the most complex and life-threatening form. However, no cohesive synthesis of the pathogenesis of the disease and its impact on specific non-traditional populations who are at a heightened risk of frequent and/or prolonged exposures. A literature review identified the comprehensive factors that determine the severity and determinates of the disease, the characteristics of non-traditional high-risk populations, and mitigation and control measures. Humanitarian aid workers, Peace Corps volunteers, missionaries, international business travelers, travelers visiting friends and relatives, and military service members are at a heightened risk for dengue infection due to recurrent and long-term travel to dengue-endemic regions, where they may have continuous or repeated exposures. A comprehensive, One Health approach should be employed to fight the spread of dengue infections. Synthesizing the clinco-epidemiology of dengue with available prevention and mitigation measures, including the use of vaccines, allows for the development of a framework for recommendations for travelers with repeated high-risk exposures. One of the best prevention methods is a tailored pre-travel health assessment covering various topics, including illness risk, primary prevention of vector contact, and health history. After establishing previous infection through a serum study, administering vaccines for travelers to endemic and hyperendemic areas should be considered. Travel health providers must be aware of barriers to prevention, such as non-compliance, inaccurate risk perception, and vaccine hesitancy, and devise strategies to mitigate these barriers. Dengue is a real and present threat whose reach will expand with travel, trade, and the expansion of the habitable range of the vector.

5328

HIGH CONFIDENCE AND DEMAND FOR HEPATITIS E VACCINE DURING AN OUTBREAK IN BENTIU, SOUTH SUDAN: A QUALITATIVE STUDY

Aybüke Koyuncu[1], Kinya Vincent Asilaza[2], John Rumunu[3], Joseph Wamala[4], Priscillah Gitahi[2], Zelie Antier[2], Jetske Duncker[2], Patrick Nkemenang[2], Primitive Gakima[5], Melat Haile[5], Etienne Gignoux[5], Manuel Albela[5], Kiendende Chong[3], Monica Rull[5], Andrew Azman[6], Iza Ciglencki[5], Robin Nesbitt[7]

[1]Johns Hopkins University; Epicentre, Baltimore; Paris, MD, United States, [2]Médecins Sans Frontières, Bentiu, South Sudan, [3]Ministry of Health, Juba, South Sudan, [4]World Health Organization, Juba, South Sudan, [5]Médecins Sans Frontières, Geneva, Switzerland, [6]Johns Hopkins University; Médecins Sans Frontières, Baltimore; Geneva, MD, United States, [7]Epicentre, Paris, France

In Bentiu internally displaced persons camp, large outbreaks of hepatitis E have occurred in 2015-16, 2019, and 2021-22. In response to the 2021 outbreak, South Sudanese Ministry of Health with support from Médecins Sans Frontières implemented the first-ever mass reactive vaccination campaign with HEV239 (Hecolin; Innovax). The target population for the campaign was individuals 16-40 years old, including pregnant women, residing in Bentiu camp. We aimed to assess knowledge, attitudes, and practices related to hepatitis E and the vaccine in Bentiu camp. We conducted 8 focus group discussions (FGDs) with community leaders, the general population of vaccine-eligible adults, vaccine eligible pregnant women, and healthcare workers. The Behavioral and Social Drivers of Vaccination framework was selected a priori to develop FGD guides and organize emerging themes into four domains: thinking and feeling, social processes, motivation, and practical issues. Two coders used inductive thematic analysis to code all transcripts using NVivo software. Data were collected in November 2022. Most individuals had experiences with hepatitis E such as being infected themselves or witnessing infected family and/or community members. Hepatitis E was perceived as a dangerous disease, and general sanitation and cleanliness were frequently mentioned prevention strategies. Participants believed children, pregnant women, and elderly were the highest risk groups. Confidence in the benefits of hepatitis E vaccine was high and participants frequently made requests for additional hepatitis E vaccination campaigns and expanded eligibility criteria for vaccination (e.g. for children). The primary barriers to vaccination were practical issues related to being away from the camp during the campaign, fears about injections, social pressure, misinformation about side effects, and concerns about why some groups were not eligible for vaccination (e.g. young children). Personal experiences with hepatitis E illness and perceived severity of illness were drivers of high demand for hepatitis E vaccines in the first-ever use of the vaccine in an outbreak setting.

POTENT NEUTRALIZING ANTIBODIES ISOLATED FROM DONORS IMMUNIZED WITH THE 17D YELLOW FEVER VACCINE

Matheus Oliveira de Souza[1], Danielle Saunders[2], Ahmed Fahad[1], Morgan Timm[3], Yuliya Petrova[3], Kimberly Dowd[4], Bharat Madan[5], Jacy Wolfe[5], Erica Normandin[3], Amy Henry[3], Farida Laboune[3], John Misasi[3], Tulio Lima[6], Renata Alvim[6], Egan Sanchez[4], Katherine Burgomaster[4], Xiaoli Pan[1], Daniel Douek[3], Julie Ledgerwood[3], Barney Graham[3], John Mascola[3], Theodore Pierson[4], Leda Castilho[6], Yan-Jang Huang[7], Brandon DeKosky[1]

[1]Ragon Institute of MGH, MIT and Harvard / Department of Pharmaceutical Chemistry, The University of Kansas / Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA, United States, [2]Department of Diagnostic Medicine-Pathobiology, Kansas State University / Department of Biology, United States Air Force Academy, Manhattan, KS, United States, [3]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [4]Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [5]Department of Pharmaceutical Chemistry, The University of Kansas, Lawrence, KS, United States, [6]Cell Culture

Engineering Laboratory, COPPE, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [7]Department of Diagnostic Medicine/Pathobiology, Kansas State University, Manhattan, KS, United States

Yellow fever virus (YFV) is a mosquito-borne flavivirus endemic in Sub-Saharan Africa and tropical South America. The disease yellow fever causes approximately 51,000 annual deaths worldwide. A live-attenuated vaccine developed in 1937 is essential to control the spread of YFV, but the shelf life and manufacturing constraints of egg-based vaccine production, the vaccine's rare severe adverse events, and the lack of effective therapeutic options for yellow fever disease create an urgency for the development of new YFV vaccines and therapeutic tools. YFV-neutralizing antibodies could be a promising passive immunization and treatment that may also guide development of effective non-replicating YFV vaccines. In this study, we captured natively paired heavy and light chain antibody libraries from two donors that were immunized with the YFV 17D vaccine and generated yeast surface display libraries for functional antibody analysis. By screening yeast libraries with YF virus-like particles purified by chromatographic techniques, we identified three anti-YFV antibodies with potent neutralizing activity against circulating strains from Western Africa and South America, including one extremely potent antibody with a neutralizing IC50 < 5 ng/mL against the 17D vaccine strain. Passive transfer of two monoclonal antibodies protected mice in the YFV neurotropic disease mouse model via intracerebral challenge with the 17D strain. The new YFV antibodies we describe here have the potential to support development of novel YFV vaccines and may also serve as YFV outbreak countermeasures for treatment or prevention.

5330

EXPLORING POTENTIAL INDICATIONS FOR REMDESIVIR BEYOND COVID-19

Meghan S. Vermillion, John P. Bilello, Richard L. Mackman, Tomas Cihlar

Gilead Sciences, Foster City, CA, United States

Remdesivir (RDV; GS-5734; VEKLURY®), a monophosphoramidate prodrug of an adenosine analog, is the first FDA-approved antiviral therapy for COVID-19. Rapid approval and distribution of RDV for SARS-CoV-2 was enabled by preexisting safety, efficacy, and pharmacokinetic data generated during its initial development for RSV and Ebola. Beyond SARS-CoV-2, RDV and its parent nucleoside (GS-441524) have antiviral activity against multiple RNA viruses through potent inhibition of their viral RNA-dependent RNA polymerases (RdRp). Cell-based assays have shown that RDV is potent against viruses within the Paramyxoviridae, Pneumoviridae, Filoviridae, Coronaviridae, Flaviviridae, and Picornaviridae families. In vivo, the pharmacologically active nucleoside triphosphate is efficiently produced in lung and peripheral blood mononuclear cells, and antiviral efficacy has been demonstrated in animal models of RSV, Ebola, Marburg, Nipah, MERS-CoV, SARS-CoV, and SARS-CoV-2 infection. Because RDV requires intravenous administration, orally bioavailable prodrugs of the parent nucleoside are being evaluated for expanded use in outpatient populations. GS-621763, an orally bioavailable prototype prodrug of GS-441524, reduced SARS-CoV-2 replication in human primary lung cell cultures as well as in mouse, ferret, and nonhuman primate challenge models. GS-5245, another oral prodrug of GS-441524, has completed Phase I pharmacokinetic and safety evaluations and is currently in Phase III clinical trials for the treatment of high-risk COVID-19 patients. Expanded in vivo efficacy against other emerging viruses is an area of active research. Collectively, these data support continued exploration of the antiviral prophylactic and therapeutic indications of RDV and oral nucleoside analogs. Proactive characterization of preclinical efficacy across other priority pathogens can enable rapid deployment of an effective treatment in response to emerging viral threats.

5331

EVOLUTION OF A FUNCTIONALLY INTACT BUT ANTIGENICALLY DISTINCT DENGUE VIRUS (DENV) FUSION LOOP

Rita M. Meganck[1], Deanna Zhu[2], Stepahnie Dong[2], Lisa J. Snoderly-Foster[3], Yago R. Dalben[3], Devina Thiono[2], Laura J. White[2], Aravinda M. DeSilva[2], Ralph S. Baric[2], **Long Ping Victor Tse[3]**

[1]Washnigton University in St. Louis, Saint Louis, MO, United States, [2]UNC Chapel Hill, Chapel Hill, NC, United States, [3]Saint Louis University, Saint Louis, MO, United States

A hallmark of Dengue virus (DENV) pathogenesis is the potential for antibody-dependent enhancement (ADE), which is associated with deadly DENV secondary infection, complicates the identification of correlates of protection, and negatively impacts the safety and efficacy of DENV vaccines. ADE is linked to antibodies targeting the fusion loop (FL) motif of the envelope (E) protein, which is completely conserved in mosquito-borne flaviviruses and required for viral entry and fusion. In the current study, we utilized saturation mutagenesis and directed evolution to engineer a functional variant with a mutated fusion loop (D2-FL) which is not neutralized by FL-targeting monoclonal antibodies. The FL mutations were combined with our previously evolved pre-membrane (prM) cleavage site to create a mature version of D2-FL (D2-FLM), which evades both prM- and FL-antibodies but retains sensitivity to other type-specific (TS) and quaternary cross-reactive (CR) antibodies. CR serum from heterotypic (DENV4) infected non-human primates (NHPs) showed lower neutralization titers against D2-FL and D2-FLM than isogenic wildtype DENV2 while similar neutralization titers were observed in serum from homotypic (DENV2) infected NHPs. We propose D2-FL and D2-FLM as valuable tools to delineate CR antibody subtypes in serum as well as an exciting platform for safer live attenuated DENV vaccines suitable for naïve individuals and children.

5332

PHARMACODYNAMIC MODELS TO INFORM THE DESIGN OF PHASE 2 ANTIVIRAL THERAPEUTIC TRIALS FOR DENGUE

James A. Watson, Vuong N. Lam, Kien D. Thi Hue, Nguyet N. Minh, Sophie Yacoub

Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam

There are currently no effective antiviral therapeutics for the treatment of early symptomatic dengue infection. A consensus methodology for the pharmacometric assessment of candidate dengue antiviral drugs would be important for comparing trial results and improving phase 2 trial design. The time to viral clearance and the area under log-viremia curve (AUC), assessed from serial qRT-PCR measurements in plasma samples, are the most widely reported measures of virological response in clinical trials. These endpoints have not been compared formally with other metrics, notably model-based estimates of the rate of viral clearance. We analyzed prospectively gathered viral clearance profiles from >600 patients recruited in clinical trials of repurposed drugs for dengue conducted by the Oxford University Clinical Research Unit in Viet Nam over the last 15 years. We fit different phenomenological pharmacodynamic models and summary measures (single exponential decay, bi-exponential, penalized splines, AUC) and show that the rate of viral clearance, estimated from a mixed effects single exponential decay model, is a robust pharmacodynamic summary of viral clearance. The rate of viral clearance, estimated from viral densities during the first 5 days following enrollment, provides increased statistical power (reduced type 2 error) compared with time to clearance and AUC. Using these data, we take a simulation approach to derive sample size requirements for hypothetical effective antiviral drugs with varying effects on acceleration of viral clearance. We recommend that pharmacometric antiviral assessments should be conducted in patients with early dengue illness (less than 72 hours from fever onset) with twice daily serial qRT-PCR plasma samples taken over 5 days.

5333

MULTIPLEX ASSAY PERFORMANCE ACROSS VARIED GEOGRAPHICAL AND RESOURCED SETTINGS: DEMOCRATIC REPUBLIC OF THE CONGO, LIBERIA, AND HAWAII

Olivia A. Smith[1], Teri Ann S. Wong[1], Varney Kamara[1], Nicole A. Hoff[2], Angelica L. Barrall[2], Sydney Merritt[2], Davidetta M. Tekah[3], Peter S. Humphrey[3], Jean Paul Kompany[4], Placide Mbala-Kingabeni[4], Bode Shobayo[5], Julius Teahton[5], John Berestecky[6], Anne Rimoin[2], Axel T. Lehrer[1]

[1]University of Hawai'i at Mānoa, Department of Tropical Medicine, Medical Microbiology, and Pharmacology, Honolulu, HI, United States, [2]University of California Los Angeles, Fielding School of Public Health, Los Angeles, CA, United States, [3]University of Liberia, TJR Faulkner College of Science and Technology, Department of Biological Sciences, Medical Science, Monrovia, Liberia, [4]National Institute of Biomedical Research (INRB), Kinshasa, Congo, Democratic Republic of the, [5]National Public Health Institute of Liberia, Monrovia, Liberia, [6]Kapi'olani Community College, University of Hawai'i, Honolulu, HI, United States

Geographical and resource barriers may introduce biases and limitations to assay performance. Determining if assay reproducibility is compromised due to these barriers is essential for assay optimization and standardization. Sustainability is a keystone of public health equity, which includes inter-assay performance, especially for seroepidemiology or detection assays for use in local health posts, zones, or departments to direct public health interventions and policies. Multiplex technology has been used globally for seroepidemiological and vaccine response analyses; however, the performance of the assays across countries has yet to be assessed. Due to the robustness of the assay, it's hypothesized that filovirus multiplex bead-based assay performance shows limited variation across geographical and resource settings in Low Middle-Income Countries (LMICs) and High-Income Countries (HICs). On the example of "real-life" detection of filovirus-specific IgG responses using Magpix multiplex bead-based technology in laboratories in the Democratic Republic of the Congo (DRC), Liberia, and Hawai'i, United States, assay performance across countries, laboratories, and technologists has been assessed. Sources of potential variation were identified; however, there was limited variability across assays performed in each locale after assessments were conducted using correlation analyses and standardized cutoff criteria. The standardized cutoff criteria involve readouts from positive and negative control samples, population limits of detection, and validation using gaussian mixture modeling. These data suggest that our multiplex filovirus bead-based assay, used in three distinct geographical and resourced settings, performs well with reproducible results. This validated technology identifies previous exposure to filovirus antigens, including vaccine and natural infection responses, globally, with limited biases due to geographical or resourced setting changes. Sustainable and unvaried analysis of samples can not only improve local public health intervention strategies but may have global impacts as well.

IN VITRO EFFICACY OF SELECTED ANTIMALARIALS AGAINST VARIANTS OF SARS COV 2 VIRUS CIRCULATING IN PANAMA DURING 2020 2022

Nicanor Obaldia[1], Mario Quijada[1], Yamilka Diaz[1], Yaneth Pitti[1], Marlene Castillo[1], Danilo Franco[1], Carolina De la Guardia[2], Dalkiria Campos[1], Marlon Nunez[1], Lariza Mendoza[1], Eduardo Cornejo[1], Sandra Lopez[1], Ariel Magallon[1]

[1]Instituto Conmemorativo Gorgas, Panama, Panama, [2]Indicasat-AIP, Panama, Panama

With the appearance of new variants of the Severe Acute Respiratory Syndrome virus (SARS-CoV-2) that causes COVID-19, the search for new antiviral drugs against this disease has renewed interest in the possible antiviral activity of antimalarial compounds. Even though at present several chemotherapeutic agents had been screened for activity against the SARS-CoV2 virus, only a few drugs had been approved for use in humans. Studies conducted in China early in the pandemic, demonstrated that chloroquine (CQ) and hydroxychloroquine (HCQ), inhibit SARS-CoV-2 replication in vitro in African green monkey kidney cells (Vero-E6). Since then, thousands of compounds have been screened using various cell lines including Vero-E6 and human lung cancer cells (Calu-3), but the use of CQ and HCQ in humans remains controversial. In this study, we aim to compare the in vitro efficacy of a series of selected antimalarials compounds against SARS-CoV-2 variants circulating in Panama with the hypothesis that the efficacy of the compounds is variant dependent. For this purpose, we first screened twenty-six compounds for cytotoxicity in both cell lines using the methyl thiazolyl tetrazolium (MTT) assay to determine their minimal cytotoxic concentration. Preliminary results indicated that 17/26 (65%) of the compounds had a viability $\geq$ 80% in Vero-E6 cells and 26/26 (100%) in Calu-3 cells. Of these, 13/17 (76%) showed antiviral activity in Vero-E6 cells against the Delta variant, and 15/17 (88%) against the A2.5 variant. In summary, 15 compounds including 4 and 8 aminoquinolines, quinolinomethanols, sesquiterpene lactones, among others were down selected for further analysis. The inhibitory concentration 50% (IC50), cytotoxic concentration 50% (CC50), selectivity index (SI) and pre and post infection activity will be determined for these compounds. In conclusion, in this study we demonstrate that selected antimalarial, endectocidal, antiviral and antineoplastic-immunosuppressive compounds from various classes had in vitro antiviral activity in Vero-E6 and Calu-3 cells against the Delta and A2.5 variants of SARS-Cov-2 circulating in Panama.

5335

QUERCETIN HYDRATE AS A POTENTIAL ANTIVIRAL AGENT AGAINST ZIKA VIRUS

Marielena Vogel Saivish[1], Gabriela de Lima Menezes[2], Roosevelt Alves da Silva[3], Marina Alves Fontoura[4], Jacqueline Farinha Shimizu[4], Gislaine Celestino Dutra da Silva[1], Igor da Silva Teixeira[1], Natalia Franco Bueno Mistrão[1], Victor Miranda Hernandes[1], Lívia Sacchetto[1], Carolina Colombelli Pacca[1], Rafael Elias Marques[4], Maurício Lacerda Nogueira[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil, [2]Universidade Federal do Rio Grande do Norte, Natal, Brazil, [3]Universidade Federal de Jataí, Jataí, Brazil, [4]Centro Nacional de Pesquisa em Energia e Materiais, Campinas, Brazil

Zika virus (ZIKV) has re-emerged in recent decades, leading to outbreaks of Zika fever in Africa, Asia, and Central and South America. Despite its drastic re-emergence and clinical impact, no vaccines or antiviral compounds are available to prevent or control ZIKV infection. We performed a study to evaluated the potential antiviral activity of quercetin hydrate against ZIKV infection and demonstrated that this substance inhibits virus particle production in Vero cells under post infection condition. First, the MTT assay was used to determine the cytotoxicity of quercetin hydrate for Vero cells. Cell viability was well above 50% at the highest concentration (1000 µM), with cell viability corresponded to 101.1 ± 12.9% for Vero cells, at 1000 µM. No cytotoxicity was observed in cells treated with 0.5% DMSO. We initially tested the antiviral effect of quercetin hydrate on ZIKV in Vero cells since these cells are highly permissive to infection. Vero cells were incubated with 1000 - 15.625 µM quercetin hydrate or the equivalent volume of DMSO and infected with ZIKV (MOI = 0.1) under post infection condition for 48 hpi. Then virus yields were measured by viral titration (PFU/mL). The presence of DMSO did not affect the production of progeny infectious virus particles. In the post-infection assay in cells 1 h after virus infection, EC50 was 28.8 µM (95% CI 22.4-37.1 µM) and SI > 34.7. These results indicate a significant dose-dependent decrease in the production of infectious ZIKV particles in the presence of increasing quercetin hydrate concentrations. After observing the dose-dependent antiviral potential of quercetin hydrate in Vero cells, we performed kinetic infection in Vero cells. Viral progeny production in the cell supernatants was quantified by plaque assay at the indicated post-infection times to observe multiple rounds of replication over 72 h. In vitro antiviral activity was long-lasting (still observed 72 h post-infection), suggesting that quercetin hydrate affects multiple rounds of ZIKV replication.

A UNIVERSAL PURIFICATION METHOD FOR SARS-COV-2 VARIANT SPIKE ANTIGENS

Isabelle Eiser, Albert To, Ludwig Mayerlen, Troy Odo, Axel Lehrer
University of Hawaii, Honolulu, HI, United States

Many vaccine platforms, including recombinant subunit protein vaccines, have been used to prevent severe disease subsequent to SARS-CoV-2 infection. Previously we developed an adjuvanted, lyophilized SARS-CoV-2 protein vaccine capable of preventing lung pathology in non-human primates. Immunoaffinity purification with the monoclonal antibody CR3022 was employed for antigen purification. Due to the evolution of the SARS-CoV-2 receptor binding domain in new variants, purification of current variant spike antigens with this efficient method is impossible. We demonstrate here a universal, tagless purification method applicable to all SARS-CoV-2 like spike proteins with minimal impact on the remaining antigen receptor binding sites by restoring the CR3022-binding epitope in our engineered BA.1 and BA.5 spike variant constructs. Reverted spike protein genes of BA.1 and BA.5 sub-variants were transfected into Drosophila S2 cells to produce stably expressing cell lines. Supernatants containing native BA.1 or the engineered versions of BA.1 and BA.5 were used for purification on CR3022- and ACE2-coupled affinity columns. Initial purification of native BA.1 spike construct using CR3022-immunoaffinity failed to extract measurable quantities of purified protein but purification with ACE2 resulted in low yields of purified protein. Reversion of the mAb epitope in BA.1 and BA.5 constructs allowed for efficient purification using CR3022. Binding affinity to ACE2 receptors remained the same between naive and reverted forms of BA.1 and BA.5 spike proteins. Restoring the CR3022 epitope on the Omicron variant spike therefore allows for effective immunoaffinity purification of a tagless, minimally modified antigen. This may therefore constitute a universal method for purifying SARS-CoV-2 spike proteins with minimal impact on the remaining epitopes and may streamline production of antigens for serosurveillance and rapid subunit protein vaccine production with a uniform, pre-approval process to combat new and evolving variants. It could potentially also be used for the generation of other purpose-engineered vaccine antigens.

DESIGNING THERAPEUTICS BIOSIMILAR OF COMMERCIALIZED MABS TO MINIMIZE LETHAL EFFECTS OF DENGUE HEMORRHAGIC FEVER: IN-SILICO APPROACH

Ayeasha Siddika Lamia, Md. Mahmudul Hasan
International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Dengue virus (DENV) with its 4 flavivirus serotypes, is responsible for dengue hemorrhagic fever (DHF) and dengue shock syndrome and contributes to 390 M infections yearly, worldwide. Due to antibody-dependent enhancement (ADE), vaccines are worsening DHF. Unavailability of therapeutics, drive this study to design biosimilars of existing FDA-approved therapeutics mAbs to neutralize Dengue Ag-Ab immune complex and reduce the pathogenesis of DHF.Envelope protein sequence of 4 serotypes of DENV, their conserved domain, epitope regions, antigenicity were retrieved, identified, predicted and aligned respectively. The 7 selected FDA-approved therapeutic mAbs (PDB ID: 6VJA, 6TCS, 7DHA, 5GGU, 5VL3, 5UDE and Nirsevimab) and Fcγ of Anti-Dengue specific IgG sequence and structure, were retrieved. Molecular docking was conducted between therapeutics mAbs with Ag, Ab separately. Later, amino acids modification were performed on existing mAbs to design biosimilar model with a wide coverage range for blocking all serotypes of DENV, and validated them. Finally, DENV Ag-Ab immune complex with modeled biosimilar mAbs were docked for final screening.Out of the 7, both existing and modified Nirsevimab, Tremelimumab, and Omalizumab showed better binding affinity (ΔG values range -10 to -20.4 kcal/mole, where ΔG < -9.3 kcal/mole preferable for therapeutic drugs), dissociation score and smallest eigenvalue with dengue Ag-Ab immune complex. The 306-318 amino acid sequence of the E protein of DENV is the conserved epitopic domain with an antigenic score of 0.8 (where >0.7 is considered an immune response generating threshold). Among 13 amino acids, FVKEETQH amino acids are common among all serotypes, and others are unique. The modified mAbs cover the entire epitopic C terminal region of all serotypes, along with the Fc gamma region of anti-dengue IgG.The proposed 3 candidate biosimilars of commercialized mAbs fulfilled the criteria for the therapeutic potential to neutralize ADE in DHF. Further in vitro studies are required for biopotency and toxicity determination to investigate their effectiveness in immediate patient management.

NIPAH VIRUS THERAPEUTICS: A SYSTEMATIC REVIEW FOR CLINICAL PRIORITISATION

Xin Hui Chan[1], Ilsa Haeusler[1], Zakiul Hassan[1], Junko Takata[1], Shanghavie Loganathan[1], Bennett Choy[1], Tara Hurst[1], Eli Harriss[2], Jake Dunning[1], Miles Carroll[1], Peter Horby[1], Piero Olliaro[1]
[1]Pandemic Sciences Institute, University of Oxford, Oxford, United Kingdom, [2]Bodleian Libraries, University of Oxford, Oxford, United Kingdom

First identified in 1998 in Malaysia and Singapore, Nipah virus infection is a bat-borne zoonotic disease spread through contaminated body fluids of infected mammals. The case fatality rate (CFR) is 40-75% and debilitating long-term neurological complications are common in survivors. The ongoing Bangladesh outbreak is the largest since 2015 with 14 cases and 10 deaths to date. There are no specific therapeutics. In recognition of this and the high CFR, Nipah is a priority pathogen on the WHO R&D Blueprint. We conducted a systematic review to identify existing therapeutic monoclonal antibodies (mAbs) and small molecules for Nipah virus and other Henipaviridae to assess the evidence available for the safety and efficacy of each to support candidate prioritisation for potential compassionate use and clinical trials. We searched (last on 30 May 2022) 7 bibliographic databases, 3 trial registries, and the Trip database and WHO website. Studies were included if they contained minimum primary data on the safety and/or efficacy of mAbs (in vivo) or small molecules (in vitro) for the treatment of Nipah, Hendra, and related Henipaviridae. From 1469 records screened, we identified 56 eligible studies: 12 on 6 sets of mAbs and 25 on 10 groups of small molecules with in vivo data, and 19 on 18 sets of small molecules with in vitro data only. Limited data were available in humans with only one clinical trial (a phase 1 study of the anti-Hendra G glycoprotein mAb m102.4 in healthy volunteers), and 8 outbreak reports, 7 of which were case series of <10 patients and 6 of which used ribavirin. There were 23 animal studies all except one of which were challenge studies with Nipah or Hendra virus. Only m102.4, remdesivir, ribavirin, and fusion inhibitory lipopeptide have been tested in non-human primates. m102.4 and remdesivir protected all and lipopeptide 2 of 6 treated primates, while ribavirin delayed but did not prevent death. Risk of bias was critical in all clinical studies other than the one trial and high or unclear in all except one of the animal studies. A rationale is presented for clinical prioritisation.

Ministry of Health Malaysia, Shah Alam, Malaysia, [6]Translational Health Science and Technology Institute (THSTI), Faridabad, India, [7]Laboratório de Imunofarmacologia, Oswaldo Cruz Institute, Fundação Oswaldo Cruz (Fiocruz), Rio de Janeiro, Brazil, [8]Departamento de Bioquímica e Imunologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [9]Drugs for Neglected Diseases initiative (DNDi), New Delhi, India

In 2019 dengue was listed by World Health Organization (WHO) as one of the top ten global health threats, with a 30-fold increase in incidence over the last 50 years reaching 400 million infected cases per year globally with majority of the disease burden in Asia and Latin America. Climate change is predicted to contribute to expansion of the mosquito vectors to new geographical areas thus leading to further increase in the number of infections. Despite significant progress on vaccine and vector control, until now, no specific dengue therapeutics are available. The Dengue Alliance includes leading research institutions from dengue-endemic countries namely India, Thailand, Malaysia, and Brazil, and was established by the Drugs for Neglected Diseases initiative (DNDi) to provide a framework for the rapid identification and progression of antivirals for dengue to clinical proof-of-concept studies by drug repurposing strategies. Here we describe the drug repurposing approach taken by the Dengue Alliance to validate antivirals as well as the initial results and overall strategy for prioritization of compounds. The in vitro efficacy for 23 compounds with reported dengue or flavivirus antiviral data were determined using cell-culture based DENV assays available at the Dengue Alliance partner labs. These assays represent a broad coverage of the DENV1-4 serotypes as well as clinical isolates and lab strains using different infection systems. The results aligned well between the labs, with most compounds ranked similarly, independent of host cell system or DENV serotype. Compounds with EC50 in low micromolar range were further evaluated by pharmacokinetics studies in mice. Two of the compounds were finally tested in A129/AG129 model for inhibition of dengue infection.

DEVELOPMENT OF A PSEUDOTYPED LENTIVIRAL REPORTER VIRUS SYSTEM FOR NIPAH AND HENDRA VIRUSES

Nathan A. Krump, Lewis J. Stafford, Kelly Dew-Budd, Benjamin J. Doranz

Integral Molecular, Inc., Philadelphia, PA, United States

The Nipah and Hendra henipaviruses are highly virulent zoonotic paromyxoviruses, a family of negative-sense single-stranded RNA viruses. Henipaviruses have been isolated from bats in Central and South America, Asia, Oceania, and East Africa and can cause disease in humans, with fatality rates of up to 75%, and across a range of mammals. Nipah virus (NiV) infection in humans can cause respiratory illness and encephalitis and outbreaks have been reported in Malaysia and Singapore and are seen almost annually in eastern India and Bangladesh and. Hendra virus (HeV) are reported nearly annually in the eastern states of Australia, primarily infecting horses but also humans. There are no specific treatments or vaccines for NiV and HeV in humans, and they are classified as Biosafety Level-4 (BSL-4) pathogens. Their infection uses the interaction of the virus envelope G protein (for cell attachment) and F protein which performs infective membrane fusion. To provide critical reagents for analyses of antibody or serum immune responses to henipaviruses, we have developed a pseudotyped lentiviral reporter virus system for Nipah (strain Malaysia 2008) and Hendra (strain Hendra horse virus/Australia/Hendra/1994) viruses, with these reporter virus particles (RVPs) displaying both G and F proteins. These replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout. We are testing the ability to neutralize the NiV and HeV RVPs using anti-G and anti-F antibodies. The use of henipavirus RVPs will overcome biosafety level restrictions on research into vaccines and therapies for these viruses.

5341

MAPPING ANTIBODY EPITOPES USING A COMPREHENSIVE MUTAGENESIS LIBRARY OF SARS-COV-2 S PROTEIN

Edgar Davidson[1], Shruthi Kannan[1], Nathan A. Krump[1], Colleen Fenn[1], Ross Chambers[1], James E. Crowe Jr[2], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Vanderbilt University, Nashville, TN, United States

To characterize the immune response to SARS-CoV-2 infection, we created a comprehensive Ala-scan mutation library of the SARS-CoV-2 S protein. We use this library to epitope map anti-SARS-CoV-2 monoclonal antibodies (MAbs) by high-throughput, rapid screens of MAb binding to each mutant S protein. Individual mutant expression plasmids are transfected into human cells to achieve native protein expression and folding. Immunoreactivity of MAbs to each mutant S protein is quantified by high-throughput flow cytometry, allowing us to identify the S protein epitope residues with the highest energetic contributions to MAb binding. We have mapped over 150 MAbs targeting the S protein, identifying conformational epitopes in the S1 receptor binding domain (RBD) and N-terminal domain (NTD), and in S2, helping characterize MAbs that neutralize and protect in animal models of disease. To provide critical reagents for analyses of MAb or serum immune responses to SARS-CoV-2 infection, we developed a pseudotyped lentiviral reporter virus system for SARS-CoV-2, with reporter virus particles (RVPs) displaying S protein. These replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout. We have produced over 70 SARS-CoV-2 RVP types incorporating variant S proteins. We also used our MPS antibody isolation platform to obtain MAbs against S protein, some of which neutralize the major Omicron variants.

5342

DEVELOPING NOVEL INHIBITORS AGAINST VENEZUELAN EQUINE ENCEPHALITIS VIRUS BY TARGETING VIRUS-HOST INTERACTIONS

Abdullahi Temitope Jamiu[1], Ivan Akhrymuk[1], Kenneth Foreman[2], Dmitri Klimov[2], Mikell Paige[2], Kylene Kehn-Hall[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]George Mason University, Manassas, VA, United States

Venezuelan equine encephalitis virus (VEEV) remains one the most important zoonotic pathogen in the family Togaviridae. VEEV is endemic to the Americas and has been responsible for periodic outbreaks of febrile and neurological disease in both equines and humans, with an associated case fatality rate of up to 10% in humans. Moreover, it is classified as a select agent by both the CDC and USDA due to its low infectious dose and ease of aerosolization and manipulation. Concerningly, there are currently no FDA-approved therapeutics or licensed vaccines against VEEV infection in humans. The VEEV capsid protein is an essential virulence factor of VEEV. The capsid protein can simultaneously bind to the host's nuclear import receptors, importin α/β1, and the host export receptor, CRM1 to form a tetrameric complex. This complex accumulates at the nuclear pore channel, halting nucleocytoplasmic trafficking, downregulating host transcription and inhibiting cellular antiviral response. We hypothesized that chemical inhibitors capable of disrupting the interaction of capsid with importin α/β1 should increase cellular antiviral response, resulting in reduced viral titers and rescue of cells from VEEV-induced cell death. Two small molecule inhibitors, I2 and 1564, were designed to disrupt the interaction between capsid and importin α. These inhibitors were well tolerated by HMC3 microglial cells with CC50 of >250 μM and >500 μM for I2 and 1564, respectively. These compounds impacted VEEV TC83 titer with >1 log10 decrease at 9 hpi. Furthermore, I2 displayed an EC50 of 2.96 μM and 1564 an EC50 of 5.38 μM against VEEV. Both compounds also rescued infected cells from VEEV-induced cell death. In order to evaluate the impact of these compounds on the capsid-importin αinteraction, we cloned two viruses that contain a V5 tag at the N-terminus of the capsid. The replication kinetics of these new viruses were similar to that of parental viruses. Moreover, they

both expresses V5-tagged capsid at various timepoints. Future studies will evaluate the impact of these compounds on capsid-importin interaction using co-immunoprecipitation and confocal microscopy.

5343

FACTORS ASSOCIATED WITH ADHERENCE TO MALARIA TREATMENT GUIDELINES IN PRIVATE DRUG OUTLETS - KISUMU COUNTY, KENYA

Fredrick O. Odhiambo[1], Elvis O. Oyugi[1], Ahmed M. Abade[2], Fredrick O. Oluoch[3], Wendy P. O'Meara[4]

[1]Ministry of Health, Nairobi, Kenya, [2]Field Epidemiology and Laboratory Training Program, Nairobi, Kenya, [3]Kisumu County Department of Health, Kisumu, Kenya, [4]Moi University, School of Public Health, Eldoret, Kenya

The malaria prevalence in Kenya is 6% and three-fold higher in the western region. The National Malaria Control Program (NMCP) seeks to avert antimalaria resistance and other adverse outcomes. We assessed the factors associated with adherence to the malaria treatment guidelines in Kisumu County private drug outlets (DOs) in 2021. A cross-sectional survey of DOs was conducted. Using a structured questionnaire to interview DO staff, we collected data on outlet characteristics (location, testing), staff factors (cadre, age, sex, training), and systemic factors (supervision, inspection). Research assistants disguised as clients used a standardized tool to record data on malaria case management observed in DOs. Analysis used proportions and measures of central tendency, dispersion. Association between independent and dependent variables was assessed using the Chi-square test. Multivariable logistic regression analysis was used to identify factors independently associated with adherence at p-value <0.05. Of the 70 participating DOs, none had a copy of the guidelines, and 60 (85.7%) were in an urban setting. Male staff were interviewed at 35 (50%) outlets, and the age group of 30-39 years constituted 30 (42.9%) of the staff. Staff adhered to the guidelines in 14 (20%) outlets. The odds of adherence to guidelines were higher among staff who had a bachelor's degree at OR 6.0 (95% CI 1.66-21.74), staff trained on malaria rapid diagnostic test (mRDT) at OR 4.4 (1.29-15.04), staff who asked about patient's symptoms at OR 3.6 (1.08-12.25), DOs with functional thermometers at OR 5.3 (1.46-19.14), DOs inspected by Pharmacy and Poisons Board (PPB) within the preceding three months at OR 9.4 (2.55-34.67), and DOs with basic infrastructure at OR 3.9 (1.01-15.00). Recent inspection by PPB (adjusted odds ratio (aOR) 4.6 (1.03-20.77) and staff trained on mRDT at aOR 4.5 (1.02-19.84) were independently associated with adherence to guidelines. Frequently inspected outlets and staff trained on mRDT tend to adhere to the guidelines. Regulatory inspection of all DOs should be done frequently. County health managers and NMCP should capacity-build DOs on mRDT use.

5344

RETROSPECTIVE STUDY TO DETERMINE ANTIMALARIAL RESISTANCE MARKERS PROFILE USING TAQMAN ARRAY CARD IN TAK PROVINCE THAILAND FROM 1998-2001

Sasikanya Thaloengsok[1], Chaiyaporn Chaisatit[1], Piyaporn Saingam[1], Paphavee (Lertsethtakarn) Ketwalha[1], Michele Spring[1], Sabaithip Sriwichai[1], Suporn Pholwat[2], Jenny Guler[2], Eric Houpt[2], **Brian Andrew Vesely[1]**

[1]AFRIMS, Bangkok, Thailand, [2]University of Virginia, Charlottesville, VA, United States

One of the major contributing factors of continued transmission of malaria is the development of drug resistant Plasmodium falciparum. Although the total number of malaria cases reported in Thailand has decreased in recent years, it is important to conduct surveillance in endemic areas to understand the emergence and spread of resistance to the first-line treatments for malaria and guiding malaria control measures. A Plasmodium TaqMan Array Card (TAC), developed at the University of Virginia was employed to identify mutations of various genes associated with anti-malarial resistance in retrospective samples. These samples were collected in 1998, 1999 and 2001 from Tak province, Thailand under a protocol evaluating the BinaxNow® Malaria Rapid Diagnostic Test, which received FDA approval in 2007. A total of 808 samples were tested, and 696 samples were confirmed malaria species positive. P. falciparum was the dominant species detected, followed by mixed infections of P. falciparum/P. vivax, P. falciparum/P. malariae, P. falciparum/P. vivax/P. malariae, and P. falciparum/P. vivax/P. ovale. Mutations in kelch13, Pfcrt, pfdhfr, pfdhps, cytochrome b, and Pfmdr1 genes were the main targets of detection. The first-line of treatment for uncomplicated P. falciparum infection during the time of the collection of these samples was mefloquine alone or in combination with sulfadoxine/pyrimethamine (S/P) and with artesunate in more recent years. No PfCYTB mutations associated with atovaquone resistance were detected. We detected mutations in PfMDR 1 at positions N86Y, Y184F, and N1042D that confer mefloquine resistance. Mutations in genes that are associated with S/P resistance, pfdhfr and pfdhps, are high in these samples. A double mutation of PfDHFR at positions 59R and 108N were presented at >99% while the majority of PfDHPS had multiple mutations, 540E and 581G. The only K13 mutations detected were a mutation at position P574L (3.33%, 1/30) in a 1998 sample, position Y493H (2.49%, 5/206) in 1999 samples, and position R539T (0.22%, 1/460) in 2001 samples. Both Y493H and R539T are WHO confirmed K13 mutations conferring resistance to artemisinin.

5345

EMERGING PLASMODIUM FALCIPARUM WITH REDUCED SUSCEPTIBILITY TO ARTEMISININ AND LUMEFANTRINE IN AFRICA

Colin Sutherland, Don A. van Schalkwyk, Sade Pratt, Lindsay Stewart, Debbie Nolder

London School of Hygiene & Tropical Medicine, London, United Kingdom

Clinical management of uncomplicated malaria caused by Plasmodium falciparum is reliant on the effectiveness of artemisinin-based combination therapy (ACT). New parasite genotypes encoding variants of the pfk13 gene are now emerging in Africa, and these are less susceptible to the artemisinin component drugs. This poses a risk of resistance selection against the partner drugs in ACT, such as lumefantrine. Case histories from UK travellers with documented ACT treatment failure, with and without pfk13 variants, and results from field surveys of resistance gene variants will be presented, together with newly collected in vitro susceptibility data for parasites of African origin adapted to long-term culture in 2022-23. The implications of these findings for future drug strategies for African malaria chemotherapy, and the design of appropriate therapeutic efficacy studies, will be considered. Finally, we will discuss the wider public health implications for Africa of a potential upsurge in prevalence of P. falciparum with reduced susceptibility to artemisinin.

5346

SANGER SEQUENCING AND DECONVOLUTION OF POLYCLONAL INFECTIONS: A QUANTITATIVE APPROACH TO MONITOR DRUG RESISTANT PLASMODIUM FALCIPARUM

Hamma Maiga[1], Morrisson Robert[2], Patrick Duffy[2]

[1]Institut National de Santé Publique, Bamako, Mali, [2]Laboratory of Malaria Immunology and Vaccinology (LMIV), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Bethesda, MD, United States

Molecular markers are used in epidemiological surveillance to monitor the emergence and spread of drug-resistant pathogens. These markers are comprised of either single nucleotide polymorphisms (SNPs) or concatenated SNPs in microbial genes that interact with drugs. Although various technical improvements in sequencing methods have been introduced to identify SNPs, current tools (conventional approach) used to measure molecular markers of anti-malarial resistance do not allow discrimination of mixed infections, and must be improved for more sensitive surveillance of anti-malarial resistance to better inform control strategies. We developed a new method to quantify molecular markers of anti-malarial

drug resistance genes [Plasmodium falciparum dihydropteorate synthase (Pfdhps) and P. falciparumdihydrofolate reductase (Pfdhfr)] by standard sequencing of amplicons and bioinformatic estimation of proportions of different genotypes in individual samples. Using parasite mixtures with known alleles, we observed a highly significant correlation between the predicted proportion of each allele with the proportion measured by sequencing and deconvolution. This was observed for Pfdhps at codons 436F, 437G and 613S/T and for Pfdhfr at codons 51I, 59R and 164L ($p < 0.001$). In studies of field samples, the mean fraction of Pfdhps was greater than 20% at codons 436F/A (95.9%,) and 437G (49.9%), but not at 431V, 540E, 581G, and 613S/T (4.7%, 0.0%, 1.2% and 1.5%, respectively); corresponding prevalences of Pfdhps were 100%, 72.5%, 50.0, 0.0%, 25.0%, and 12.5%, respectively. The mean fraction of Pfdhfr was greater than 20% at codons 51I, 59R and 108T/N (89.0%, 98.3% and 74.7%), respectively but not at 16V(0.6%), 50R(11.1%), 140L(8.6%) and 164L(8.7%); corresponding prevalences of Pfdhfr were 100%, 100%, 100%, 12.5%, 75.0%, 50.0%, and 28.6%, respectively. Our results demonstrate quantitative discrimination of varying proportions of sensitive versus resistant alleles using a cost-effective approach that incorporates Sanger sequencing of PCR amplicons with novel informatics tools for deconvolution.

IDENTIFICATION OF NEW ANTIMALARIALS TARGETING THE PLASMODIUM FALCIPARUM PROLINE TRNA SYNTHETASE

Benigno Crespo Fernández
GlaxoSmithKline, Tres Cantos, Spain

Identification of new antimalarials targeting the P. falciparum proline tRNA synthetase Benigno Crespo, Carlos Alemparte, Pilar Manzano, Emilia D'oria, Andrew Cliffon, Tony Choudhry, Gang Yao, Apirat Chaikuad, Audrey Tolbert, Chloe Oxford and Nathan Gittens

Malaria is one of the most devastating diseases in the world, causing around 65,0000 deaths in 2021, and almost 50% of the world population is at risk of being infected. Reports of resistance to Artemisinin in different regions, especially in South East Asia and recently also in Africa, is a major concern. There is an urgent need of new antimalarial treatments to replace those compromised due to resistance. Phenotypic screening has been the cornerstone in the search for new antimalarials in the last decade. However, the chemical diversity in the screening collections is currently exhausted, and little progress has been made in the identification of new modes of action. Thus, more target-based approaches are required to find new chemical starting points for hit to lead programs. Cytoplasmic prolyl t-RNA synthetase (ProRS) is one of the most chemically and genetically validated targets in Plasmodium falciparum (Pf). ProRS is the main target of Febrifugine, a Chinese traditional medicine used for centuries in the treatment of Malaria. However, Febrifugine and synthetic analogues like Halofuginone cannot be developed as antimalarials due to an unacceptable safety profile associated to their low selectivity against the human homologue.In this work, we present the strategy followed for the identification of new chemical inhibitors of Pf ProRS. GSK collection has been screened by affinity selection mass spectrometry (ASMS) and by encoded library technology (ELT) in different conditions, including ProRS alone as well as combinations of the protein with its different substrates (proline, ATP and tRNA). Identified binders were progressed to a biochemical assay to assess their activity against Pf ProRS and its human counterpart. Mode of action of selective compounds will be elucidated using resistant strains, thermal shift, biochemical assays and crystallography.

SIMPLE, INEXPENSIVE IN VITRO DRUG SURVIVAL ASSAY FOR MONITORING ANTIMALARIAL DRUG SENSITIVITY IN MALARIA ENDEMIC REGIONS

Chinedu Ogbonnia Egwu, Fatoumata Bojang, Ndey Fatou Drammeh, Aminata Seedy Jawara, Fatou K. Jaiteh, Eniyou Oriero, Alfred Amambua-Ngwa
Medical Research Council unit at London School School of Hygienen and Tropical Medicine, Banjul, Gambia

Resistance to cheap antimalarial drugs and the current artemisinin combination therapies has contributed to the sustained burden of malaria. For malaria elimination, the efficacy of current drugs needs to be monitored especially in Africa, which bears over 96% of the burden of malaria. Drug efficacy monitoring in laboratories use in vitro inhibition concentration (IC50) tests, which has been highly inconsistent and cumbersome to implement across endemic settings. Here, we present a simple and inexpensive in vitro malaria drug survival assay (mDSA) for monitoring antimalarial failure in low resource settings. In vitro drug survival assay determines the % survival and the reinvasion rate of parasite isolates exposed to a 48-hour pulse of lethal concentrations of antimalaria drugs. In this study, 32 field isolates of malaria parasites in the Gambia and the control isolates (DD2 and 3D7) were exposed to (10X IC50 cut-off) of dihydroartemisinin (DHA): 24nM, lumefantrine (LUM): 200nM, chloroquine (CQ): 200nM and piperaquine (PPQ):200nM respectively for 48h, followed by another cycle of culture in drug-free medium. The % survival and the reinvasion rate were estimated after 24h and 48h drug-free growth. Our preliminary findings show that this simple assay can consistently differentiate resistant from sensitive parasite strains for each of the antimalarial drugs. With CQ for example, the % survival was 72, 118 and 6% for the field isolates, CQ-resistant strain (DD2) and CQ-sensitive strains (3D7) respectively ($p < 0.05$). The high % survival of the field isolates, evidence of CQ resistance, was supported by the significantly higher reinvasion in the field isolate than 3D7 (0.4 vs 0, $p < 0.05$) and the no significant difference between the field isolates and DD2 (0.4 vs 1.4, $p > 0.05$). mDSA confirmed persistent CQ resistance in the Gambia. mDSA can therefore be used for surveillance of antimalarials and early detection of failure. It could facilitate drug policy to improve malaria control.

5349

ANALYSIS OF THE SUITABILITY OF USE OF MUTATIONS IN THE PVCRT-O AND PVMDR1 GENES AS MARKERS OF RESISTANCE OF PLASMODIUM VIVAX TO CHLOROQUINE IN AMAZONIC BASIN

Rebecca Abreu Fernandes Dos Santos, Natalia Almeida de Oliveira, Patricia BRASIL, Claudio Tadeu Daniel Ribeiro, **Maria de Fatima Ferreira-da- Cruz**
Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

In Brazil, approximately 139,000 malaria cases were recorded in 2021, 83% of them caused by P. vivax. In the absence of an antimalarial vaccine, the control policy is based on case management through prompt diagnosis and treatment. With the rapid emergence and dispersion of parasite drug resistance, it is necessary to monitor the effectiveness of drugs used in the treatment. In Brazil, a percentage of up to 10% of vivax malaria cases resistant to chloroquine (CQ) have already been registered. Unlike P. falciparum, there are no established molecular markers of P. vivax chemoresistance (QR) to CQ. Therefore, we investigate whether the polymorphisms in the genes pvcrt-o and pvmdr1 can be markers of QR to QC. Additionally, the pvdhfr and pvdhps genes associated with QR to the sulfadoxine-pyrimethamine (SP) were analyzed to find out the potential of using this drug in cases of QR parasites to CQ. For this, 130 samples from the Amazon Basin were studied through the polymerase chain reaction followed by target DNA sequencing. In the pvcrt-o exons, the K10 insert was present in 14% of the samples. Regarding pvmdr1, the SNPs T958M and F1076L had a frequency of 95% and 3%, respectively, while the SNP Y976F was not detected in the samples. In pvdhfr, we observed the presence of double FRTHNI (76%), triple FRTHNL (21%), and quadruple

FRTRNL (8%) mutants, and the wild-type haplotype was not found. As for pvdhps, we detected the wild type (38%) and single SGKAEV (50%), and double mutants CGKAEV (12%). Allelic combination of the pvdhfr/pvdhps genes showed that the triple FRTHNI + SGKAEV (42%) and the double FRTHNI + SAKAEV (31%) mutants were the most prevalent. Thus, it is concluded that: i) mutations in the pvcrt-o gene seem to have a low potential for association with the phenotype of QR to CQ because K10-pvcrt-o and F1076L/Y976F/T958M-pvmdr1 polymorphisms were detected in samples from patients who responded well to CQ treatment and; ii) the frequencies of double and triple pvdhfr and pvdhps mutants associated with the low percentage of non-mutated parasites seems to indicate that SP cannot be introduced as an alternative drug in cases of QR to CQ in P. vivax.

Malaria is a devastating disease that caused 619,000 deaths in 2021 worldwide. Cases of malaria have increased from previous years in part by the quick development of resistance to current antimalarials. Due to the rising resistance to current antimalarial drugs such as chloroquine and artemisinin, there is an urgent need to discover and develop new chemotherapeutic agents that engage new targets in the malaria parasite. This research focuses on a novel antimalarial with a unique β-carboline scaffold known as PRC1584. It is known that exposure to dihydroartemisinin (DHA) induces a quiescent state in Plasmodium falciparum ring stage. Quiescence is a mechanism of Plasmodium survival especially from drug treatment. This phenomenon increases the risk of clinical failures following artemisinin-based combination therapies by slowing parasite clearance and allowing the selection of parasites resistant to partner drugs. We investigated if short exposure of PRC1584 also induces quiescent and/or kills the proliferating ring stage and if PRC1584 has activity against DHA-induced quiescent ring stage in the presence or absence of DHA-resistance. We used the ring survival assay (RSA) and the quiescent-stage survival assay (QSA) to assess the antiplasmodial activity of PRC1584 and its analogs in the presence and absence of DHA resistance. Our studies revealed that only 8 hours of exposure to PRC1584 kills both the proliferating ring stage and the DHA-induced quiescent rings of P. falciparum independently of the presence of DHA-resistance. In addition, we are using these assays to guide optimization of this series as preclinical leads. Altogether, these results revealed that PRC1584 displays a fast-killing profile and that it may act through a novel mechanism of action. Identifying if new antimalarials may also facilitate the development of quiescent-ring stage is extremely important, as this could result in recrudescence and treatment failure.

PLASMODIUM FALCIPARUM KELCH13 R561H SPREAD AND EMERGENCE OF OTHER ARTEMISININ PARTIAL RESISTANT MUTATIONS ACROSS RWANDA USING A SITE AND TEMPORAL RAPID POOLING STRATEGY

Neeva Wernsman Young[1], Gashema Pierre[2], David Giesbrecht[1], Tharcisse Munyaneza[3], Alec Leonetti[1], Rebecca Crudale[1], Vincent Iradukunda[2], Ntwari Jean Bosco[2], Corine Karema[4], Jean-Baptiste Mazarati[2], Jonathan J. Juliano[5], Jeffrey A. Bailey[1]

[1]Brown University, Providence, RI, United States, [2]INES-Ruhengeri, Musanze, Rwanda, [3]National Reference Laboratory, Rwanda Biomedical Center, Kigali, Rwanda, [4]Quality Equity Health Care, Kigali, Rwanda, [5]University of North Carolina - Chapel Hill, Chapel Hill, NC, United States

Recent monitoring has detected multiple emerging Plasmodium falciparum kelch13 (K13) propeller gene mutations across East Africa. Mutations, such as R561H in Rwanda and C469Y/F, and A675V in Uganda, have been increasing and are associated with artemisinin partial resistance mainly manifesting as delayed clearance after treatment with ACTs and recrudescence. Coordinated surveillance efforts are necessary to track these K13 mutants and inform control efforts. Here we apply pooled sequencing to provide a rapid initial assessment of population allele frequency at collection sites. Whole blood samples (n=2,703) from malaria-positive patients were collected from 20 Rwandan health centers from May to December 2022. Samples were pooled at equal volume, stratified by site and month to generate 104 pools. DNA was extracted using magnetic beads and genotyped using molecular inversion probe targeted sequencing of K13 and other resistance genes. Site allele frequencies were calculated weighted by the number of samples in a given pool. From a single round of sequencing, R561H was detected at 13 of 17 sites with an average frequency of 23.5% (0 to 70.3%). The highest site frequency clustered in the center of the country. At sites bordering the DRC (n=2), no R561H was found, suggesting R561H may not have spread west. In Bugaragara, in northeast Rwanda, we found 49.7% average frequency that progressively increased monthly from October to December (0.54% to 94.1%). Notably, A675V, previously seen in Uganda, was found at 6.81% across 11 sites. Other mutations observed to be spreading in Uganda, C469F and C469Y, were not observed at any site. Concerningly, G449A was at 7.11%, a WHO candidate resistance mutation never before reported in Africa but associated with a two-fold prolonged parasite clearance half-life in Asia. It was detected at 2 sites including Tanda (20.8%) where a large outbreak has been occurring. Overall, it appears multiple K13 mutations are rapidly expanding in Rwanda, further endangering control efforts and treatment efficacy with the potential of engendering partner drug resistance.

PLASMODIUM FALCIPARUM DRUG RESISTANCE MARKERS AND GENETIC STRUCTURE IN MOZAMBIQUE, 2015-2022

Simone Salvador Boene[1], Clemente da Silva[1], Arlindo Chidimatembue[1], Glória Matambisso[1], Abel Nhama[1], Eusebio Macete[1], Pedro Aide[1], Francisco Saúte[1], Eduard Rovira-Vallbona[2], Debayan Datta[2], Alfredo Mayor[2]

[1]Fundação Manhiça (CISM), Maputo, Mozambique, [2]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

Antimalarial drug resistance is a global threat to malaria control and elimination, and is of particular concern in Mozambique, one of the four African countries which account for over half of all malaria deaths worldwide. Here we aimed to describe antimalarial resistance markers in Mozambique and interrogate parasite population structure using genome-wide microhaplotyes. To achieve this, we performed Plasmodium falciparum amplicon and whole genome sequencing using Next Generation Sequencing in 2251 malaria-infected blood samples collected in 2015 and 2018 in seven provinces of Mozambique. Another batch of samples (1300) from 2021 and 2022 are being tested at the laboratory and the results will be presented at the conference. The preliminary results revealed

a total of 32 non-synonymous mutations in the kelch13 gene, although none of them are currently associated with artemisinin resistance. No mutations or frequencies above 1% were observed for the rest of markers, except for 184F in pfmdr1 (59%), 51I/59R/108N in pfdhfr (>95%) and 437G/540E in pfdhps (>81%). The frequency of pfdhfr/pfdhps quintuple mutants increased from 80% in 2015 to 89% in 2018 (p<0.001), with a lower expected heterozygosity and higher relatedness of microhaplotypes surrounding dhps mutants than wild-type parasites suggestive of recent selection. pfdhfr/pfdhps quintuple mutants also increased from 72% in the north to 95% in the south (2018; p<0.001). This resistance gradient was overlaid with a concentration of mutations in position 436 of pfdhps (17%) in the north, a south-to-north increase in the genetic complexity of P. falciparum infections (p=0.001) and a microhaplotype signature of regional differentiation. The results of this study revealed several public health implications such as, appropriate efficacy of artemisinin-based combination therapy for P. falciparum treatment, chemoprevention with sulphadoxine-pyrimethamine is still recommended in areas with high rates of pfdhfr/pfdhps quintuple mutations, the evidence of a return of chloroquine therapeutic efficacy in Mozambique.

INADEQUATE ARTEMETHER-LUMEFANTRINE TREATMENT RESPONSE IN A 15-MONTH OLD PATIENT WITH UNCOMPLICATED FALCIPARUM MALARIA IN WESTERN KENYA: A CASE REPORT

Raphael Okoth[1], Alfred Odindo[1], Benjamin Opot[1], Agnes Cheruiyot[1], Catherine Muriuki[1], Redemptah Yeda[1], Gladys Chemwor[1], Jackline Juma[1], Edwin Mwakio[1], Maurine Mwalo[1], Risper Maisiba[1], Farid Abdi[1], Duke Omariba[1], Dennis Juma[1], Timothy Egbo[2], Hoseah M. Akala[1]

[1]Department of Emerging and Infectious Diseases (DEID), United States Army Medical Research Directorate-Africa (USAMRD-A), Kenya Medical Research Institute (KEMRI) / Walter Reed Project, Kisumu, Kenya, [2]United States Army Medical Research Directorate-Africa (USAMRD-A), Kisumu, Kenya

Despite global efforts against malaria, inadequate treatment response and resistance to artemisinin combination therapies (ACTs) are becoming increasingly common, posing a threat to malaria elimination efforts. In endemic zones, ACTs are recommended as first-line treatment of uncomplicated malaria. This case report describes a 15-month old male patient with uncomplicated falciparum malaria who did not respond to artemether-lumefantrine treatment. The patient weighed 9.0 kilograms and presented at Kisumu sub county referral hospital with classical symptoms of uncomplicated falciparum malaria. The first dose of Artemether Lumefantrine (AL) was administered by a health worker who monitored the patient for an additional 30 minutes to confirm drug retention. Subsequent treatment doses were given to the parent for continuation at home. The patient returned on day 7 without symptoms, but was diagnosed with malaria by RDT and microscopy, revealing a Plasmodium falciparum single species infection at 0.2% parasitemia. Molecular diagnosis was done using PCR followed by genotyping for merozoite surface proteins 1 (MSP1), MSP2 and GLURP, which confirmed the presence of P. falciparum and recrudescence from identical alleles between the initial and subsequent samples. No non-synonymous mutations were observed in the Kelch 13 propeller gene of the parasite. Pharmacokinetic analyses, in vitro drug sensitivity tests, and further genotyping of putative drug resistance markers are underway. This case highlights the challenge of inadequate treatment response to artemether-lumefantrine in a young child with uncomplicated falciparum malaria in Western Kenya. The molecular diagnosis and genotyping results confirmed recrudescence of P. falciparum from identical alleles between the initial and subsequent samples. This case report emphasizes the need for close surveillance of antimalarial efficacy and parasite response to current antimalarial drugs in endemic zones. Further research is required to identify the underlying mechanisms of artemether-lumefantrine treatment failure and to develop effective strategies to combat resistance.

5354

PREVALENCE OF MOLECULAR MARKERS OF RESISTANCE TO SULFADOXINE-PYRIMETHAMINE (SP) BEFORE AND AFTER COMMUNITY DELIVERY OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY: A MULTI-CONTRY EVALUATION IN SUB-SAHARAN AFRICA

Antía Figueroa-Romero[1], Daniel Bissombolo[2], Martin Meremikwu[3], Arsène Ratsimbasoa[4], Charfudin Sacoor[5], Iwara Arikpo[3], Elsha Lemba[2], Abel Nhama[5], Rianasoambolanoro Rakotosaona[6], Mireia Llach[1], Clara Pons-Duran[1], Sergi Sanz[1], Laurence Ma[7], Cécile Doderer-lang[8], Christina Maly[9], Elaine Roman[9], Franco Pagnoni[1], Alfredo Mayor[1], Didier Menard[8], Raquel González[1], Clara Menéndez[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Medecins d'Afrique, Kinshasa, Congo, Democratic Republic of the, [3]Cross River Health and Demographic Surveillance System, University of Calabar, Calabar, Nigeria, [4]Université de Fianarantsoa, Fianarantsoa, Madagascar, [5]Centro de Investigação em Saude de Manhiça, Manhiça, Mozambique, [6]Centre National d'Application des Recherches Pharmaceutiques, Antananarivo, Madagascar, [7]Institut Pasteur, Université Paris Cité, Biomics Platform, C2RT, Paris, France, [8]Université de Strasbourg, Institute of Parasitology and Tropical Diseases, UR7292 Dynamics of Host-Pathogen Interactions, Strasbourg, France, [9]Jhpiego, Johns Hopkins University Affiliate, Baltimore, MD, United States

The effectiveness of community delivery of intermittent preventive treatment (C-IPT) of malaria in pregnancy (IPTp) with sulfadoxine-pyrimethamine (SP) was evaluated in selected areas of the Democratic Republic of Congo (DRC), Madagascar, Mozambique, and Nigeria. We aimed to assess the potential development of Plasmodium falciparum resistance to SP since it could threat C-IPTp effectiveness. Health facility-based, cross-sectional surveys were conducted before and three years after C-IPTp implementation in an area with C-IPTp, and in a neighboring area with no C-IPTp implementation in the four project countries. Dried blood spots from children under five years of age with clinical malaria were collected. SP resistance-associated mutations of the P. falciparum dhfr (N51I/C59R/S108N/I164L) and dhps (I431V/S436A/K437G/K540E/A581G/A613S) genes were analyzed. A total of 4983 children were recruited between June 2018 and November 2021. In DRC, the dhfr/dhps IRNI/ISGEAA haplotype remained lower than 10% in both areas and timepoints. In Mozambique the prevalence of this haplotype was over 60% at baseline and remained stable in both areas after C-IPTp implementation. No P. falciparum isolates harboring the dhps ISGEAA haplotype were found in Nigeria. In Madagascar only five isolates harboring this haplotype were found in both timepoints. No isolates were found to carry the dhps triple mutant ISGEGA haplotype. Community IPTp did not increase the prevalence of molecular markers associated with SP resistance after three years of implementation. These findings reinforce C-IPTp as a strategy to optimize malaria control during pregnancy and support the World Health Organization guidelines for prevention of malaria in pregnancy.

5355

ESTIMATING THE IMPACT OF PLASMODIUM FALCIPARUM DHFR AND DHPS MUTATIONS ON PROTECTIVE EFFICACY OF SULFADOXINE-PYRIMETHAMINE: EVIDENCE FROM THERAPEUTIC EFFICACY STUDIES AND IMPLICATIONS FOR MALARIA CHEMOPREVENTION

[4]Department of Infectious Disease, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom, [5]MRC Unit The Gambia at the London School of Hygiene and Tropical Medicine, Serrekunda, Gambia, [6]Centre de recherche entomologique de Cotonou, Cotonou, Benin, [7]Division of Clinical Pharmacology, Department of Medicine, University of Cape Town, Cape Town, South Africa, [8]South African National Institute for Communicable Diseases, Johannesburg, South Africa, [9]Department of Immunology and Microbiology, Centre for Medical Parasitology, University of Copenhagen, Copenhagen, Denmark

Sulfadoxine-pyrimethamine (SP) is the recommended treatment for perennial malaria chemoprevention (PMC). The triple mutation in the Plasmodium falciparum dihydrofolate reductase (dhfr) gene (N51I/C59R/S108N) affects tolerance to pyrimethamine and it is largely fixed and saturated across sub-Saharan Africa. Additional mutations in the dihydropteroate synthase (dhps) gene may threaten the protective efficacy of SP, but this relationship has not yet been quantified. Here, we retrospectively analyse PCR-corrected re-infection data from therapeutic efficacy trials to quantify protective efficacy and duration of protection offered by SP (or SP-artesunate [AS]) against parasites with different genetic levels of SP resistance. We use a mathematical model that accounts for site-specific genotype frequencies and incidence rates and fit Weibull survival curves to the duration of drug protection using Bayesian methods. In a study in Benin (2003-2005), where 87.1% of patients had the quadruple mutation (dhfr triple + dhpsA437G), we estimated the mean duration of protection to be 29.9 days (95% Credible Interval [CrI]: 10.4-61.0) for SP and 27.0 days (95%CrI: 11.1-44.9) for SP-AS. The 30-day protective efficacy was 89.7% and 84.9%, respectively. In Malawi in 2005, where 91.6% of participants had the quintuple mutation (quadruple + dhpsK540E), SP-AS provided 14.8 (95%CrI: 10.3-30.3) days protection (30-day protective efficacy: 41.7%). In Tanzania in 2006, SP was estimated to provide 14.8 days (95%CrI: 3.6-39.9) protection against quintuple mutant parasites and 10.7 days (95%CrI: 6.1-30.1) against sextuple mutant parasites (quintuple + dhpsA581G). These findings suggest that accumulation of dhps mutations is associated with a reduced ability of SP to protect against infection. Further data will be added to refine these estimates and to quantify protection against different parasite strains. These findings, along with recent molecular survey data, can help parameterize models quantifying the impact of seasonal or perennial chemoprevention in areas with different genotype frequencies to inform scale-up of these interventions.

5356

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION (SMC) ON MOLECULAR MARKERS OF PLASMODIUM FALCIPARUM ANTIMALARIAL DRUG RESISTANCE IN KOULIKORO HEALTH DISTRICT, MALI

Fousseyni Kane[1], Bourama Traore[1], Helene JØRGENSEN[2], Mahamoudou Toure[1], Daouda SANOGO[1], Soumba Keita[1], Mahamadou Diakite[1], Michael Alifrangis[2], Helle Holm HANSSON[2], Seydou Doumbia[1]

[1]University Clinical Research Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali, [2]Centre for Medical Parasitology, Department of Immunology and Microbiology, University of Copenhagen, Copenhagen, Denmark Department of Infectious Diseases, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark, Copenhagen, Denmark

With the scale-up of Seasonal Malaria Chemoprevention (SMC), emergence of antimalarial drug resistance may impair the efficacy of the control strategy. This study examined potential changes in Plasmodium falciparum genes related sulfadoxine-pyrimethamine plus amodiaquine (SP+AQ) and dihydroartemisinin-piperaquine (DHA-PQ) resitance. The study was carried out during effectiveness trials using DHA+PQ as an alternative drug treatment to SP+AQ among children under 10s children in Koulikoro region, Mali. DNA was extracted from dried blood spots and P. falciparum PCR positive samples underwent targeted amplicon sequencing (Miseq Illumina) for drug resistance profiling, including SNPs in Pfdhfr, Pfdhps, Pfmdr1, Pfcrt, PfKelch13 and Pfexo. Furthermore, copy number variations (CNVs) in Pfmdr1 and Plasmepsin2 were analyzed by qPCR. In total, 215 and 341 P. falciparum positive samples were successfully genotyped for 2019 and 2020, respectively. High prevalence of the triple mutated Pfdhfr haplotype at 51I-59R-108N (IRN) was observed for both 2019 (95%) and 2020 (93.3%), with no significant difference between two years and the drug arms (p>0.05). For Pfdhps, overall the most prevalent haplotypes observed were the single mutant haplotypes at 431-436-437G-540-581-613 (IAGKAA/ISGKAA), at approx 60% while more mutant haplotypes were observed in low numbers; for 2020 e.g. VAGKAA (0.6%), VAGKGS (1.2%) and ISGEAA (2.4%). No significant differences between the years and between the drug arms were observed (p=1.57). For Pfmdr1 and Pfcrt haplotypes, the most prevalent Pfmdr1 haplotype, NFD (86-184-1246) at >50% did not differ between the years and drug arms while the Pfcrt wildtype CVMNK haplotype increased from 39% to 52% from 2019 to 2020 (p=0.01), no difference between the drug arms were observed (p=0.44). For PfK13 gene, few non-synonymous SNPs were observed, none seemed important. Finally, few CNVs (<2%) in Pfplasmepsin2 and Pfmdr1 were observed for 2019 and 2020. Despite some minor variations from year to year, deploying SMC using either SP+AQ or DHA-PQ does not seem to select for molecular markers of drug resistance in the tested population in Mali.

5357

SYSTEMATIC REVIEW & GEOSPATIAL MODELLING OF MOLECULAR MARKERS OF RESISTANCE TO ARTEMISININS & SULFADOXINE-PYRIMETHAMINE IN PLASMODIUM FALCIPARUMIN INDIA

Surveillance for genetic markers of resistance can rapidly provide valuable information on the likely efficacy of antimalarial drugs but needs to be targeted to ensure optimal use of resources. We conducted a systematic review of publications in 7 databases and 5 languages to compile resistance marker prevalence data from studies in malaria endemic states of India published between Jan 2014 and Mar 2022. The earliest identified study was conducted in 1994 and the most recent in 2019 with a median time lag from sample collection to publication of 4 years. Fewer studies were conducted in states with moderate or low malaria endemicity, with no studies conducted in Uttarakhand. In all, pfk13, pfdhfr, and pfdhps genotype data from 2953, 4148, and 4222 samples, respectively, were extracted from these publications. They were combined with data from the WorldWide Antimalarial Resistance Network (WWARN) Molecular Surveyor database and fed into a hierarchical geostatistical model to produce maps of the predicted prevalence of the pfk13 and pfdhps markers and of the associated uncertainty. Zones with a high predicted pfdhps 540E prevalence of >15% were identified in Central, Eastern and Northeastern India. The predicted prevalence of pfk13 mutants was non-zero at only few locations outside the Northeastern states but these were within or adjacent to the zones with high prevalence of pfdhps 540E. The highest uncertainty in the predicted prevalence was from zones where fewer or no studies were conducted but also from locations where conflicting data were collected, possibly reflecting evolving prevalence over time. This study identified regions with high predicted pfdhps 540E prevalence where there may be a higher probability of artesunate-sulfadoxine-pyrimethamine failures due to the predicted co-prevalence of pfk13 mutants. However, the accuracy of these predictions remains to be confirmed as they are based on very sparse data. This work can be applied to conduct systematic, targeted,

and eventually comprehensive molecular surveillance to help identify the treatments most likely to be effective for malaria elimination from India and elsewhere.

PHARE, A BIOINFORMATICS PIPELINE TO DETECT MINORITY HAPLOTYPES IN MULTICLONAL SAMPLES

Philipp Wagner[1], Salome Hosch[1], Ulrich Vickos[2], Christian Nsanzabana[1], Tobias Schindler[1], Claudia Daubenberger[1]

[1]SwissTPH, Allschwil, Switzerland, [2]Ospedale Pediatrico Bambino Gesù, Rome, Italy

The emergence of drug-resistant clones of Plasmodium falciparum is a major public health concern, and the ability to detect and track the spread of these clones is crucial for effective control and treatment. However, in endemic settings, patients are often infected with more than one clone at the same time making it likely to miss drug resistant clones using traditional molecular screening methods. The PHARE pipeline is a novel method for detecting these minor haplotypes in multiclonal samples sequenced using the Oxford Nanopore MinION platform. The pipeline was validated on three control datasets containing P. falciparum DNA of four laboratory strains at varying mixing ratios, achieving high recall and accuracy rates in all control datasets. Additionally, the pipeline was successfully tested on clinical samples from children in a paediatric hospital in the Central African Republic infected with P. falciparum. The pipeline can be used on any gene and was tested with amplicons of pfdhps, pfdhfr, and pfk13. The PHARE pipeline helps to provide a complete picture of the population structure of the malaria parasite and can be easily adapted to other pathogens and genes.

5359

MOLECULAR MARKERS OF RESISTANCE TO SULFADOXINE-PYRIMETHAMINE AND AMODIAQUINE IN THE HEALTH DISTRICT OF BOUSSÉ, BURKINA FASO

Cheick Compaore[1], Craig Bonnington[2], Kevin Baker[2], Paul Sondo[3], Adama Traore[1], Boulaye Dao[4], Ambroise Ouedraogo[4], Sidzabda Kompaore[4], Gauthier Tougri[5], Halidou Tinto[3]

[1]Malaria consortium, Ouagadougou, Burkina Faso, [2]Malaria consortium, London, United Kingdom, [3]3.Institut de Recherche en Sciences de la Santé (IRSS), Clinical Research Unit of Nanoro (CRUN), Nanoro, Burkina Faso, [4]Permanent secretary for malaria elimination, Ministry of health, Ouagadougou, Burkina Faso, [5]Ministry of health, Ouagadougou, Burkina Faso

Malaria is a major public health problem in Burkina Faso and is the leading cause of hospital visits, hospitalization and death. Malaria transmission is seasonal, with peaks observed during the rainy season. Seasonal malaria chemoprevention (SMC) is a major prevention intervention to reduce malaria burden in children under five, the most vulnerable group. It is recommended that SMC be implemented in areas where Sulfadoxine-Pyrimethamine (SP) and Amodiaquine (AQ) remains effective. Resistance to SP or AQ may reduce the chemopreventive efficacy of SPAQ from clinical malaria in children. To date, there is little data on the prevalence of SP and AQ resistance in Burkina Faso. After more than 7 years of SMC implementation, there are no up to date data on the level of molecular markers of SP and AQ resistance. This study aims to investigate the levels of parasite resistance to SP and AQ in the health district of Boussé in the Central Plateau region. A cross-sectional survey in health facilities was conducted. A total of 150 RDT positives samples were collected prior to the start of the 2022 SMC campaign from 08th to 10th July 2022. After the 4 SMC cycles in the area, 150 other RDT positive samples were collected between 7th to 11th November to 2022. Parasite DNA was extracted using Quiagen Kit at the Molecular Biology laboratory. Parasite genotyping is ongoing and the main outcome measure is the prevalence of molecular markers associated with SP (codons 108, 51 and 59 in dhfr and 437, 540 and 581 in dhps) and amodiaquine (codons 72-76 Pfcrt and 86, 184, 1034 and 1246 pfmdr1) in collected blood samples. This study will provide evidence of the resistance level of AQ and SP in Burkina Faso. Furthermore, this study will inform policy makers about the selective pressure of the SMC intervention on the circulating parasite population in Burkina Faso.

RESISTANCE HAPLOTYPES DETECTED IN PREGNANT WOMEN IN BURKINA FASO RECEIVING INTERMITTENT PREVENTIVE TREATMENT WITH SULFADOXINE-PYRIMETHAMINE (SP)

Pedro J. Berzosa

National Centre of Tropical Medicine - Institute of Health Carlos III, Madrid, Spain

Malaria in pregnancy (MiP) is still a significant public health problem, with effects on both mother and offspring's. The latter includes maternal anaemia, foetal loss, premature delivery and delivery of low birth-weight infants. For the control of MiP, the World Health Organization (WHO) recommends prompt detection and treatment of all malaria cases associated with preventives measures such as of long-lasting insecticide treated nets (LLINs) together with administration of intermittent preventive treatment with sulfadoxine-pyrimethamine (IPTp-SP). Resistance to SP is widespread throughout Africa, so IPTp use may be compromised in the near future. As a result, we sought to analyse the genetic profile of Plasmodium falciparum resistant to SP in pregnant women who have received IPTp-SP. This study included 418 samples from pregnant women attending antennal care visit (ANC). In all P. falciparum isolates the presence of SNPs in pfdhfr and pfdhps genes related with SP resistance were studied. Malaria prevalence was 45% (190/418) and 49% (205/418) respectively using microscopy and PCR. The species prevalence was 97.6% for P. falciparum and 2% for P. vivax. The only haplotype detected was the partially resistant (pfdhfr 51-59-108 pfdhps 437); fully and super resistant were not found. Apart from haplotypes, any SNP of importance for resistance has been described. Looking at the result of detected haplotype, partially resistance, indicate the selective pressure exerted by SP is not so high in the country. The use of SP is reserved exclusively for IPTp and nowadays for seasonal malaria chemoprevention (SMC) even if the coverage of 3 IPT-SP doses is not optimal. In addition, these pregnant women included in the study did not have severe malaria in any of the cases indicating the protection of IPTp. Continuous monitoring of genetic profile of malaria parasites infecting pregnant women who are part of IPTp-SP strategy in optimal conditions could give insightful information for the design of effective prevention measures.

DIAGNOSTIC PERFORMANCE OF NXTEK™ ELIMINATE MALARIA PF TEST FOR THE DETECTION OF PLASMODIUM FALCIPARUM IN SCHOOL CHILDREN WITH ASYMPTOMATIC MALARIA

Abdissa Biruksew Hordofa[1], Ashenafi Demeke[2], Prof. Zewdie Birhanu[1], Estifanos Kebede[1], Lemu Golassa[3], Evans M. Mathebula[4], Prof. Delenasaw Yewhalaw[1]

[1]Jimma University, Jimma, Ethiopia, [2]Minch Health Science College, Arba Minch, Ethiopia, [3]Aklilu Lemma Institute of Pathobiology, Addis Ababa University, Addis Ababa, Ethiopia, [4]University of Pretoria, South Africa, Ethiopia

Plasmodium falciparum malaria is one of the major roadblocks to the elimination program due to presence of a large number of portions of the population are asymptomatic infection. Targeting such reservoirs is critical to interrupting transmission and enhancing elimination efforts. The NxTekTM Eliminate Malaria Pf test is a highly sensitive rapid diagnostic test (hsRDT) for the detection of HRP-2. However, knowledge gaps exist in Ethiopia on the diagnostic performance of hsRDT in school children with asymptomatic malaria. We collected 994 blood samples between September 2021 and January 2022 to evaluate the diagnostic performance of the hsRDT for the detection of P. falciparum in healthy school children with asymptomatic infection. We compared the performance of hsRDT to the conventional malaria RDT, SD Bioline Pf/Pv (cRDT) in the field and microscopy

examinations of all samples and molecular analysis using QuantStudioTM 3 real-time PCR system (qPCR). We then used both microcopy and qPCR as reference methods. We found that the prevalence of P. falciparum was 1.51%, 2.2%. 2.2% and 4.52%, by microscopy, hsRDT, cRDT and qPCR, respectively. When we used qPCR as reference, the sensitivity of hsRDT was higher (48.89%) than the microscopy (33.3%), and showed 100% specificity and a positive predictive value (PPV). Microscopy showed similar specificity and PPV as hsRDT. Using microscopy as a reference, the sensitivities of both hsRDT and qPCR were similar (100%). Both RDTs demonstrated identical diagnostic performances in both comparison methods.The hsRDT has the same diagnostic performance as cRDT but improved diagnostic characteristics than microscopy for detection of P. falciparum in school children with asymptomatic malaria. These results suggest that the new malaria RDT, NxTek Eliminate Malaria Pf, could be a useful tool for the National Malaria Elimination Plan in Ethiopia to screen for P. falciparum in asymptomatic schoolchildren.

Malaria elimination in Senegal requires accurate diagnosis of all Plasmodium species. P. falciparum is the most prevalent species in Senegal, although P. malariae, P. ovale, and recently P. vivax have also been reported. Nonetheless, most malaria control tools, such as Histidine Rich Protein 2 Rapid Diagnosis Test (HRP2RDT,) can only diagnose P. falciparum. Thus, HRP2RDT misses non-falciparum species and P. falciparum infections that fall below the limit of detection. These limitations can be addressed using highly-sensitive Next Generation Sequencing (NGS). This study assesses the burden of Plasmodium species in the community using targeting NGS. We collected 3000 samples from symptomatic and asymptomatic individuals in 2021 from three sites in Senegal (Diourbel, Kaolack, and Gabou). All samples were tested using HRP2RDT and photoinduced electron transfer PCR (PET-PCR), which detects all Plasmodium species. Targeted sequencing of the nuclear 18S rRNA and the mitochondrial cytochrome B genes was performed on PET-PCR positive samples. Malaria prevalence by HRP2RDT showed 9.4% (94/1000) and 0.2% (2/1000) in Diourbel and Kaolack, respectively. PET-PCR detected 295 positive samples, of which 29.8 %, 11.6 %, and 17.6 % were in Diourbel, Kaolack, and Gabou, respectively. Successful sequencing of 141/295 samples detected P. falciparum (80.3%), P. malariae (13.4%), and P. vivax (6.3 %). P. vivax was co-identified with P. falciparum in seven samples. Sequencing also detected two HRP2RDT-negative single infections of P. vivax from Gabou and Kaolack. Our findings demonstrate circulating non-falciparum species at the community level, highlighting the need for improved malaria control strategies and accurate diagnostic tools to better understand the prevalence of non-falciparum species countrywide.

5363

PERFORMANCE EVALUATION OF NOVEL LDH-BASED RAPID DIAGNOSTIC TESTS FOR PLASMODIUM FALCIPARUM AND P. VIVAX MALARIA ON FROZEN SPECIMENS: IMPLICATIONS FOR ACCESS TO RADICAL CURE

Marcelo Brito[1], Dhelio Pereira[2], Anne Almeida[1], Gabrielly Santos da Silva[1], Emmanuelle Lira[3], Vanessa Castro[3], **Stephanie Zobrist**[4], William Sheahan[4], Eduardo Garbin[2], Emily Gerth-Guyette[4], Sampa Pal[4], Allison Golden[4], Marcus VG Lacerda[5], Gonzalo J. Domingo[4]

[1]Fundação de Medicina Tropical Dr Heitor Vieira Dourado (FMT/HVD), Manaus, Brazil, [2]Centro de Pesquisa Em Medicina Tropical (CEPEM), Porto Velho, Brazil, [3]Fundação de Medicina Tropical Dr Heitor Vieira Dourado (FMT/HVD) and Universidade do Estado do Amazonas, Manaus, Brazil, [4]PATH, Seattle, WA, United States, [5]Fundação de Medicina Tropical Dr Heitor Vieira Dourado (FMT/HVD) and Instituto Leônidas & Maria Deane (ILMD), Manaus, Brazil

New diagnostics with the potential to improve access to safe radical cure treatment options for Plasmodium vivax (Pv) malaria, such as point-of-care (POC) glucose-6-phosphate dehydrogenase (G6PD) tests and novel malaria rapid diagnostic tests (RDTs), are being deployed. Of particular interest are plasmodium lactate dehydrogenase (pLDH)-based RDTs with improved limits of detection (LODs) that translate into robust clinical performance for Plasmodium falciparum (Pf) infections with histidine-rich protein 2 (HRP2) and HRP3 gene deletions and for Pv clinical infections. In the Brazilian Amazon, where malaria is prevalent, such tools have the potential to optimize malaria case management. Venous blood specimens in K2EDTA were collected in Porto Velho, Rondônia, Brazil, as part of a cross-sectional diagnostic accuracy study to evaluate the performance of the POC STANDARD G6PD Test (SD Biosensor, South Korea) against a reference spectrophotometric G6PD assay. At the time of specimen collection, all participants were tested for malaria by microscopy per the standard of care. Stored frozen specimens from this study were used to evaluate the performance of three novel RDTs with improved LODs for LDH: the BIOCREDIT Malaria Ag Pf/Pv (pLDH/pLDH), Pf (pLDH), and Pf (HRPII/pLDH) (Rapigen Inc., South Korea). A commercially available comparator RDT (Málaria P.f / Pan ECO Teste - TR.003, ECO Diagnóstica, Brazil) was also run. RDT performance was evaluated against a reference assay for Pf and Pv malaria. The study evaluated 981 specimens, including 70 Pf-positives, 262 Pv-positives, 15 positives for both Pf and Pv, and 631 negative specimens by PCR. Diagnostic performance of the RDTs in terms of sensitivity and specificity will be reported. The implications of test performance for malaria case management will also be considered. The proportion of PCR-confirmed Pv malaria cases that would be eligible for radical cure treatment under different testing algorithm scenarios will be presented, considering the BIOCREDIT Ag Pf/Pv (pLDH/pLDH) RDT results, the microscopy results, and the individual's G6PD status.

LOW PREVALENCE OF PFHRP2 AND PFHRP3 DELETIONS AND NON-FALCIPARUM MALARIA INFECTIONS IN OUTPATIENTS SAMPLED DURING THE 2021 BENIN HEALTH FACILITY SURVEY

Jessica N. McCaffery[1], Aurore Hounto[2], Ahmed S. Hassani[3], Douglas Nace[1], Patrick Condo[4], Virgile Gnanguenon[4], Hortense Kossou[5], Virgile Capo-Chichi[6], Julien Aissan[2], Augustin Kpemasse[2], Mateusz Plucinski[1], Dean Sayre[1], Cyriaque Affoukou[2], Eric Rogier[1]

[1]CDC, Atlanta, GA, United States, [2]NMCP Benin, Cotonou, Benin, [3]CDC PMI, USAID Benin, Cotonou, Benin, [4]USAID, Cotonou, Benin, [5]PMI Benin, Cotonou, Benin, [6]LEADD, Cotonou, Benin

Benin's entire population is at high risk for malaria infection and Benin relies on rapid diagnostic tests (RDTs) detecting the Plasmodium falciparum histidine-rich protein 2 (HRP2) to diagnose malaria. However, no studies to date have systematically investigated the presence of pfhrp2 and pfhrp3 gene deletions in Benin that could affect RDT performance. Estimates of non-falciparum malaria infections, which are undetectable by HRP2-based RDTs, are also lacking in Benin. In this study, a total of 1413 outpatients at a nationally representative sample of 115 health facilities in Benin in 2021 were enrolled. Participants were tested using an HRP2-based RDT (Bioline Malaria Ag P.f Device 05FK50, Abbott) and provided dried blood spot samples for multiplex screening of six Plasmodium antigens and PCR genotyping for pfhrp2 and pfhrp3 deletions. In total, 729 participants (51.6%) tested positive for any Plasmodium antigen, and 673 (47.6%) had high HRP2 antigen levels. 56 Plasmodium antigen-positive isolates with low HRP2 antigen signals had DNA extracted for genotyping. Six non-falciparum single-species infections were identified by PET-PCR among study participants: two were P. ovale (0.3% of 729 Plasmodium-antigen positive), and four were P. malariae (0.5%, 4/729). No P. falciparum isolates lacking the pfhrp2 gene were found. Two infections (0.3%, 2/729) carried

P. falciparum parasites with pfhrp3 gene deletions, but these persons still tested positive by HRP2-based RDT and had received appropriate antimalarial treatment. Using laboratory HRP2-antigen positivity as the comparator assay, the sensitivity of the field HRP2-based RDT was found to be 89.5% (614/686), and the specificity was 86.4% (616/713). Overall, this study identified no pfhrp2 gene deletions in P. falciparum parasites and few non-falciparum Plasmodium infections. In conclusion, these data provide evidence for the continued use of HRP2-based RDTs for malaria case management in Benin.

5365

PLASMODIUM FALCIPARUM KELCH13 MUTATIONS IN ERITREA AND ASSOCIATIONS WITH PFHRP2 AND PFHRP3 DELETIONS

Selam Mihreteab[1], Karen Anderson[2], Irene Molina de la Fuente[3], Colin Sutherland[4], David Smith[2], Jane Cunningham[5], Khalid B. Beshir[4], **Qin Cheng[6]**

[1]National Malaria Control Program, Ministry of Health, Asmara, Eritrea, [2]Australian Defence Force Malaria and Infectious Disease Institute/QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]Carlos III Institute of Health/University of Alcala, Madrid, Spain, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]World Health Organization, Geneva, Switzerland, [6]Australian Defence Force Malaria and Infectious Disease Institute/QIMR Berghofer medical Research Institute, Brisbane, Australia

Eritrea was the first African country to report a high prevalence of pfhrp2/3-deleted P. falciparum parasites causing high rates of false-negative RDT results and to switch away from exclusive use of HRP2-based RDTs in 2016. While country's high reliance on malaria RDTs was likely the major driving force behind the rapid expansion of pfhrp2/3-deleted parasites, antimalarial (artesunate-amodiaquine) use and host immunity could also exert selection pressures contributing to the spread. We retrospectively examined SNPs in the P. falciparum kelch13 gene from samples collected from the Northern Red Sea (Semenawi Keih Bahri) Zone in 2016 before the RDT switch and from the Gash Barka, Anseba and Debub Zones in 2019 where pfhrp2/3 status had been determined. No non-synonymous changes were identified from the 2016 sample set. However, five different single non-synonymous SNPs were detected in samples collected after 2019. The most prevalent non-synonymous SNP was R622I as it was detected in samples collected from all locations with an overall prevalence of 11.7% (ranging from 2.5% to 28%). Preliminary analysis suggests that the pfk13 R622I variant is twice as likely to occur in single pfhrp3-deleted than dual pfhrp2/3-deleted parasites, and three-times as likely compared to parasites without pfhrp2/3 deletions. Parasites carrying the R622I mutation have diverse microsatellite marker haplotypes, suggesting that they have evolved from different genetic backgrounds. The results suggest that there is an association between pfhrp3 deletion and pfk13 R622I mutation, and indicate an interaction between RDT and artemisinin selection pressure on the parasite population. Continued monitoring of the trend of pfhrp2/3 deletion and pfk13 R622I mutation will help to decipher this interaction. Full analysis will be presented at the meeting.

5366

SURVEILLANCE OF PLASMODIUM FALCIPARUM HRP23 GENE DELETIONS IN MOZAMBIQUE: A PROSPECTIVE STUDY

Clemente da silva

Manhica Health Reseach Center, Maputo, Mozambique

The integration of genomic data into routine surveillance activities has the potential to increase actionable intelligence for making programmatic decisions on the optimal mix of control and elimination measures. With the aim of informing Mozambique's national malaria control and elimination strategies, we are conducting a prospective genomic surveillance study to monitor molecular markers of drug and diagnostic resistance, characterize transmission sources in low transmission settings, and assess the value of genomic data to infer levels of transmission. For the use case of assessing Plasmodium falciparum histidine rich protein 2/3 (pfhrp2/3) deletions, associated with parasite escape from rapid diagnostic test (RDT) detection, sampling took place in 2022 at 40 health facilities from five districts across four provinces of medium/high transmission during both rainy and dry seasons from 2-10 year-old children seeking care for malaria symptoms were tested by both routine HRP2-based rapid diagnostic test (RDT) and P. falciparum lactate dehydrogenase (LDH)-RDT, to identify potential false negative results due to pfhrp2/3 deletions among malaria clinical cases. Dried blood spots (DBS) were collected from those testing positive by one or both RDTs (n=200). Samples were identified according to discrepant results between LDH-RDT and HRP2- RDT, and all DBS from children with a negative HRP2-RDT but positive LDH-RDT will be tested for the presence of deletions by multiplex real time quantitative polymerase chain reaction qPCR. This approach not only detects the pfhrp2 and pfhrp3 genes but also the presence of the human reference genes humtubb (human beta-tubulin) and the pfldh gene.Samples with the following results (humtubb+, pfldh+ and pfhrp2/3-) and (humtubb+, pfldh+ and pfhrp2/3+) will be considered with deletion and no deletion respectively. The results will be incorporated into the Integrated Malaria Information Storage System (iMISS), so that the NMCP has full access to them and can recommend a change in RDTs if the prevalence of pfhrp2/3 gene deletions causing false-negative RDTs among symptomatic patients at national level is above 5%.

5367

AVAILABILITY OF FREE MALARIA RAPID DIAGNOSTIC TESTS AT THE LEVEL OF PRIVATE PHARMACIES FOR THE CONFIRMATION OF THE DIAGNOSIS OF MALARIA PRIOR TO ANTIMALARIAL TREATMENT: RESULTS OF A PILOT PROJECT IN BENIN: MARCH TO DECEMBER 2022

Edgard Mario Badet[1], Virgile Gnaguenon[2], Eugène Montcho[2], Patrick Condo[2], Cyriaque D. Affoukou[1], Gislaine Loko Djidjoho[3], Mourchidath Adegbindi[3], Pascal Fafeh[4], Vivien Akan[1]

[1]Programme Notional de Lutte contre le Paludisme, COTONOU, Benin, [2]United States President's Malaria Initiative, USAID, Cotonou, Benin, COTONOU, Benin, [3]U.S President Malaria Initiative, The USAID Global Health Supply Chain (GHSC) – Technical Assistance (TA) Francophone Task Order (FTO), COTONOU, Benin, [4]Plateforme du Secteur Sanitaire Privé, COTONOU, Benin

World Helth Organisation recommends that all suspected cases of malaria undergo parasitological testing to confirm the diagnosis. Private pharmacies are a reality of the supply of care corresponding to the demand of an increasingly growing urban population. They hold 1/3 of the volume of antimalarial sales in the private sector, which represents 70% of the total volume of antimalarial sales in Benin. Most antimalarials are sold in these pharmacies without confirmation of the parasitological diagnosis. In order to improve the diagnosis of uncomplicated malaria in these private pharmacies in Benin, the National Malaria Control Program initiated the training of pharmacists for the free implementation of rapid diagnostic tests for malaria and artemisinin-based therapeutic combinations subsidized in 44 out of the total of 340 private pharmacies currently operating in Benin. These 44 pharmacies were selected according to well-defined criteria, in particular possession of an authorization to open and operate, adherence to malaria control guidelines, agreement to comply with the rules for the transfer of subsidized ILPs, monthly reporting of consumption data on DHIS2 and the availability of a space to carry out malaria rapid diagnostic tests within the pharmacy. This training of pharmacists, followed by the implementation of the inputs, extended over the period from March to December 2022. Two supervision visits were carried out in July and December 2022 to assess the use rapid diagnostic tests in pharmacies in accordance with relevant directives. Of the 44 pharmacies trained, 35 (80%) started the diagnosis of malaria in accordance with the standards. A total of 2,030 patients suspected of uncomplicated malaria agreed to be tested as a preliminary to treatment for uncomplicated malaria in the 35 pilot pharmacies. Of the 2,030 patients who were tested, 560 tested positive and received antimalarial treatment, representing a positivity rate of 27.58% of rapid

diagnostic tests. Clients who had a negative RDT test result were referred for further assessment. A follow-up will be done for compliance with malaria diagnostic guidelines in the pharmacies.

5368

MALARIA PARASITEMIA ESTIMATES BASED ON HRP2 AND PLDH ANTIGEN CONCENTRATIONS FROM A LARGE HOUSEHOLD SURVEY IN NIGERIA: HOW MUCH DIFFERENCE DOES RAPID DIAGNOSTIC TESTS (RDTS) PERFORMANCE MAKE?

Laura Steinhardt[1], Abiodun Ogunniyi[2], Nwando Mba[2], Ado Abubakar[3], Perpetua Uhomoibhi[4], McPaul Okoye[5], Nnaemeka Iriemenam[5], Michael Aidoo[1], Eric Rogier[1], Chikwe Ihekweazu[2]

[1]CDC, Atlanta, GA, United States, [2]Nigeria Centre for Disease Control, Abuja, Nigeria, [3]Institute for Human Virology, Nigeria, Abuja, Nigeria, [4]Ministry of Health, Abuja, Nigeria, [5]CDC, Abuja, Nigeria

Countries increasingly rely on rapid diagnostic tests (RDTs) to estimate malaria prevalence in large surveys. Estimates depend on RDT ability to detect malaria antigens, especially when asymptomatic low-density infections predominate. We assessed how malaria prevalence varies by RDT sensitivity, using antigen data from a large national household survey in Nigeria. Dried blood spots (DBS) prepared during the 2018 Nigeria HIV/AIDS Indicator and Impact Survey were tested for Plasmodium falciparum-specific HRP2 and pan-species pLDH antigens on a multiplex bead assay. Standard antigen concentration curves were also created by testing known concentrations of HRP2 and pLDH on the bead assay. For HRP2, we calculated prevalence that would result from a conventional RDT (cRDT, assumed limit of detection (LoD)=6.7 nanograms HRP2/mL, the median concentration in pre-qualification testing samples) and hypothetical 10-fold more sensitive RDTs (uRDT) and 2-fold less sensitive RDTs (pRDT). For pLDH, we used thresholds for a 'good' RDT (LDHRDT, LoD = 13.6 nanograms/mL) and a 2-fold more sensitive one (sLDHRDT). Estimates account for sampling probability and complex survey design. Our sample comprised all children <15 years (n=31,468), a sample of women of reproductive age (n=9,634), and all respondents 15+ years in 11 of Nigeria's 36 states (n=47,811) with a DBS. Estimated prevalence varied significantly by HRP2 RDT, at 24.3% (95% CI: 23.0, 24.8) by cRDT, 45.1% (95% CI: 44.7, 45.6) by uRDT, and 19.5% (95% CI: 19.1, 19.9) by pRDT. Estimates significantly differed by RDT for all age groups, including children <5 years (CU5), the target for malaria household surveys [cRDT: 28.7% (95% CI: 27.3, 30.1); uRDT: 47.0% (95% CI: 45.3, 48.7); pRDT: 24.4% (95% CI: 23.1, 25.6)]. pLDH RDT differences were smaller but significant for all age groups, including CU5 [LDHRDT: 31.9% (95% CI: 30.3, 33.4); sLDHRDT: 35.8% (95% CI: 34.2, 37.3)]. Malaria prevalence estimates can differ significantly depending on RDT sensitivity. RDT selection is especially important in settings with asymptomatic, low-density infections.

MALARIA MISDIAGNOSIS IN THE ROUTINE HEALTH SYSTEM IN ARBA MINCH AREA DISTRICT IN SOUTHWEST ETHIOPIA: AN IMPLICATION FOR MALARIA CONTROL AND ELIMINATION

Engida Yigezu[1], Biniam Wondale[1], Daniel Abebe[2], Girum Tamiru[1], Nigatu Eligo[1], Bernt Lindtjørn[3], Endalamaw Gadisa[2], Fitsum Girma Tadesse[2], **Fekadu Massebo**[1]

[1]Arba Minch University, Arba Minch, Ethiopia, [2]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [3]Centre for International Health, University of Bergen, Bergen, Norway

Accurate diagnosis of malaria is vital for the appropriate treatment of cases and to interrupt its transmission. The objective of this study was to compare microscopy with nested polymerase chain reaction (PCR) to diagnose malaria infections. A cross-sectional survey on health facilities was conducted from November 2019 to January 2020. Two hundred fifty-four microscopically negative and 193 microscopically positive malaria cases were assessed. Of the 193 malaria-positive patients, 46.1% (95% confidence interval (CI): 38.9-53.4) (89/193) were Plasmodium falciparum infections, 52.3% (95% CI: 45.0-59.5) (101/193) were P. vivax infection, and 1.6% (3/193) had mixed infection of P. falciparum and P. vivax. Of the microscopically positive cases of P. falciparum, 84.3% (75/89) were confirmed as P. falciparum, 3.4% (3/89) were P. vivax and 11.2% (10/89) were mixed infections with P. falciparum and P. vivax, and only one case was negative molecularly. Similarly, of the microscopically positive cases of P. vivax cases, 92.1% (93/101) were confirmed as P. vivax, 5.9% (6/101) were P. falciparum and 1% (1/101) was a mixed infection. A single case was negative by molecular technique. Of the 254 microscopically negative cases, 0.8% of patients tested positive for P. falciparum and 2% for P. vivax. Using PCR a reference, the sensitivity of microscopy for detecting P. falciparum was 89%, and for P. vivax, it was 91%. The specificity of microscopy for detecting P. falciparum was 96%, and for P. vivax, it was 98%. However, the sensitivity in detecting mixed infection of P. falciparum and P. vivax was low (8%). Thus, many P. falciparum and P. vivax mixed infections were microscopically overlooked and underreported. In addition, there were cases left untreated or inappropriately treated. Therefore, the gaps in the microscopic-based malaria diagnosis should be identified and regularly monitored to ensure the accuracy of the diagnosis.

5370

USER PERCEPTIONS OF A SMARTPHONE-BASED MALARIA RAPID DIAGNOSTIC TEST (RDT) AID FOR COMMUNITY AND PRIVATE CLINIC-BASED HEALTH WORKERS IN WESTERN KENYA

Wycliffe Waweru[1], Shawna Cooper[2], Christopher Lourenco[3], Malia Skjefte[4], Christine Oduor[1], Sam Smedinghoff[2], Stephen Poyer[4]

[1]Population Services International, Nairobi, Kenya, [2]Audere, Seattle, WA, United States, [3]Population Services International, Washington, DC, United States, [4]Population Services International, Washington DC, DC, United States

The increased use of malaria rapid diagnostic tests (mRDTs) has helped bridge a quality case management gap since their adoption. This is especially true in remote areas with limited access to malaria microscopy. However, health workers face challenges with proper administration and interpretation of mRDT results. Audere, PS Kenya, and PSI partnered on a study in Busia County, Western Kenya to assess the acceptability and feasibility of using HealthPulse, a smartphone RDT reader app developed by Audere, to aid health workers in mRDT administration, interpretation, and tracking with the aim of improving the mRDT testing process. 203 community health volunteers (CHVs) and 23 private clinic health workers (PCHWs) used their personal mobile devices during the study. Using a pre-and post-quantitative design, the study compared the accuracy of health worker mRDT interpretations before and after HealthPulse was introduced. During the intervention phase, process data, including participant interactions with the app, stock, and medication distribution, were recorded in addition to qualitative baseline and end line surveys. Results indicated that HealthPulse holds potential as a mobile tool that can be scaled up for adoption in low resource settings with possible utility as a supportive supervision, diagnostic, and surveillance tool. Among the 5,278 uploaded encounters, 879 (16.7%) included an image of a previously used mRDT. Process control data showed that most encounters (89.4%) were uploaded within the recommended 30-minute time frame and that 73.4% of uploaded photos passed the app's artificial intelligence (AI) quality check on the first submission. The majority of participants felt that the app was helpful to the diagnostic process and end line survey results showed that 99.6% of participants found the app useful and 90.1% found the app easy to use. Follow-on qualitative work with 25 study participants indicated that HealthPulse provided an opportunity for health workers to submit evidence of their RDT result reporting activities, which enabled them to build credibility and trust with their peers, supervisors, and community members.

LACK OF MUTANT PLASMODIUM FALCIPARUM PARASITES WITH PFHRP2AND PFHRP3 GENE DELETIONS IN ANLONG VENG AND KRATIE, CAMBODIA

Cielo Pasay[1], David Smith[1], Karen Anderson[1], Jennifer Sally[2], Brian Vesely[2], Mariusz Wojnarski[3], Worachet Kuntawunginn[3], Nillawan Buathong[3], Kittijarankon Phontham[3], Lychhea Huot[3], Qin Cheng[4]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]Australia Defence Force Malaria and Infectious Disease Institute, Brisbane, Queensland, Australia

Malaria transmission remains low in Cambodia after intensive intervention measures aimed towards malaria elimination over a decade ago. HRP2-based RDTs have been widely used as a diagnostic tool to guide antimalarial treatment, in particular to contain artemisinin resistance. Despite these, no RDT failures caused by mutant Plasmodium falciparum parasites with pfhrp2 and pfhrp3 gene deletions have been reported in the country. In this study, we investigated the genes' status in 116 P. falciparum infected blood samples collected between Oct 2018 and Oct 2019 in Anlong Veng and Kratie towns, Cambodia during an antimalarial therapeutic efficacy trial. Plasmodium spp was confirmed by microscopy, RDT and 18S rRNA multiplex PCR. pfhrp2 and pfhrp3 gene status was determined by conventional PCR and probe-based multiplex qPCR. HRP2 expression was also verified by ELISA and samples with negligible levels of HRP2 were tested for pLDH. Microsatellite genotyping was also performed to determine polyclonality, MOI and genetic relatedness. Despite low transmission levels (polyclonality=3.3%, MOI=1.03) and widespread use of HRP2-based RDTs that provide a fertile ground for the emergence of mutant parasites lacking HRP2, no pfhrp2 and/or pfhrp3 deletion was detected in this cohort of samples from northern and western region of Cambodia by both PCR methods. This was confirmed by parasite expression of HRP2. The result suggests a very low population frequency of pfhrp2/3 deletions in the survey location at the time of survey. The continued use of HRP based RDTs is not likely a public health issue at this time. However, continuous surveillance in Cambodia is still required to monitor possible emergence of mutant parasites causing malaria RDT failures.

PERFORMANCE AND USABILITY EVALUATION OF NOVEL MALARIA RDTS FOR IMPROVED CASE MANAGEMENT IN KÉDOUGOU, SENEGAL

Stephanie Zobrist[1], Babacar Souleymane Sambe[2], **Divya Soni**[3], Aissatou Diagne[2], Ibrahima Sarr[2], Arona Sabene Diatta[2], William Sheahan[1], Sampa Pal[1], Allison Golden[1], Rebecca Green[1], Yakou Dieye[4], Moustapha Cisse[4], Gonzalo J. Domingo[1], Makhtar Niang[2]

[1]PATH, Seattle, WA, United States, [2]Institut Pasteur de Dakar, Dakar, Senegal, [3]PATH, New Delhi, India, [4]PATH, Dakar, Senegal

The emergence of pfhrp2/3-deleted parasites threatens histidine-rich protein 2 (HRP2)-based rapid diagnostic test (RDT) performance. High-performing, heat-stable RDTs that include Plasmodium falciparum (Pf)-lactate dehydrogenase (LDH) targets are needed to address limitations of current products and improve management of malaria patients. From November 2021 to February 2022, a cross-sectional diagnostic accuracy study was conducted in Kédougou, Senegal, to evaluate the clinical performance and usability of three novel RDTs with improved limits of detection for pfLDH. Febrile patients aged ≥6 months were recruited at health facilities. Capillary blood was tested using a standard-of-care RDT (SD Bioline Ag Pf [#05FK50]) and three novel RDTs: the BIOCREDIT Malaria Ag Pf (pLDH), Pf (HRPII/pLDH), and Pf/Pv (pLDH/pLDH) (Rapigen Inc., South Korea). Venous blood was collected to repeat the novel RDTs, and microscopy slides were prepared. Venous samples were frozen and tested with a reference polymerase chain reaction (PCR) assay. Antigen concentration was determined using the Q-Plex™ Human Malaria array (5-Plex) (Quansys Biosciences, USA). A questionnaire was used to evaluate the ability of health workers to comprehend labels and interpret results of the Ag Pf (pLDH) and Pf (HRPII/pLDH) tests. Among 220 febrile patients enrolled in the diagnostic accuracy study, 154 (70%) were Pf-positive by reference PCR. No P. vivax cases were detected on any assay, and one suspected HRP2/3 deletion case was identified by antigen concentration results. Of all RDTs evaluated, the BIOCREDIT Ag Pf (HRPII/pLDH) had the highest performance at 78% sensitivity (70.9%–84.5%) and 89% specificity (79.4%–95.6%). RDTs performed better in terms of sensitivity and specificity when compared to the Quansys antigen than when compared to the PCR reference. All RDTs performed significantly better than microscopy (with a sensitivity of 53%) in this setting. Among 20 health workers, both evaluated tests yielded acceptable usability scores. The BIOCREDIT RDTs show promising usability and performance to address current diagnostic gaps.

5373

DEVELOPMENT OF A FIELD-DEPLOYABLE RT-PCR DIAGNOSTIC SYSTEM FOR PLASMODIUM DETECTION IN ANOPHELES SPECIES.

Madhavinadha Prasad Kona, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Surveillance of infectious mosquitoes is important for the implementation of appropriate vector control strategies. Diagnostic assays are essential for monitoring the infection prevalence and geographical range of pathogens in mosquito vector populations. We have evaluated a field-deployable Real-Time PCR platform as a molecular diagnosis tool for the detection of Plasmodium species. This surveillance system includes field deployable preparation of mosquito DNA samples and RT-PCR using MGB probe targeting18S rRNA gene and other stage-specific genes using the portable bCUBE RT-PCR machine connected to an automatic data interpretation system. Parasite genomic DNA was detected in individually infected Anopheles mosquitoes and in pools of 5 to 50 mosquitoes. Additionally, emerging drug resistant Plasmodium infection using markers containing K13 SNP mutations, were detected in the field Anopheles population. Conclusively, this surveillance system provides an efficient molecular approach for the detection of Plasmodium in anopheline vectors in the field and therefore has a potential as a practical field-deployable diagnostic test for vector-borne disease surveillance programs.

5374

EVALUATION OF MALARIA RAPID DIAGNOSTIC TEST SERVICES PERFORMANCE AT HEALTH POSTS IN ETHIOPIA

Adugna Abera, Abnet Abebe, Desalegn Nega, Bokretsion Gidey, Ashenafi Assefa, Geremew Tasew, Adugna Woyessa

Ethiopian Public Health Institute, Addis Ababa, Ethiopia

The use of RDT by health extension workers at community level in Ethiopia has been a core element of diagnosis since 2005. However, there is limited information regarding malaria RDT use, performance and factors influencing utilization among health extension workers in Ethiopia. Evaluating performance of testing malaria using RDT at health post and addressing the bottlenecks is a vital step to improve community-based malaria treatment and inform decision at local levels is worth addressing. The aim of this study was to evaluate the performance of malaria rapid diagnostic test services at health posts as well as factors influencing malaria rapid diagnostic tests utilization in health posts in Ethiopia. A cross-section survey was conducted in 221 health posts and their 330 staffs found in 72 districts between March and October 2020. The districts were randomly sampled from nine regions and one City Administration. Interview of health extension worker using a structured questionnaire and standardized checklist and panel test was employed to collect data from selected health posts. Open Data Kit software was used to collect and share data with EPHI server. A total of 330 health extension workers from 221 health posts took part in the survey, which implies 1.49 on average. Nine out of ten health posts practice malaria diagnosis using RDT following the SOP, while discrepancies are observed

in the rest particularly in Somali and Gambella Regional States. A moderate agreement, 89.5% (k: 0.46), was observed between the malaria RDT result and the blood film reading using expert microscopist reding. The sensitivity and specificity of the RDTs were 70.2% and 91.1% respectively, referring to expert microcopy. Conclusions, this study demonstrated that most of the health posts practice the standard national guideline and moderate agreement between RDT and expert microscopist reading is obtained. Future capacity building scheme must prioritize on how to improve the use of standard guideline and avoid discrepancy in malaria diagnosis.

5375

A NOVEL COMPETITIVE ELISA ASSAY TO MEASURE AMODIAQUINE CONCENTRATION IN CHILDREN RECEIVING SULFADOXINE-PYRIMETHAMINE PLUS AMODIAQUINE FOR SEASONAL MALARIA CHEMOPREVENTION IN KOULIKORO, MALI.

Ilo Dicko[1], Hawa Boukary Diarra[1], Daouda Sanogo[1], Soumba Keita[1], Fousseyni Kane[1], Ibrahim Sanogo[1], Mountaga Diallo[1], Nadie Coulibaly[1], Mamadou Wague[1], Hamady Coulibaly[1], Jingqi Qian[2], Baomin Wang[2], Liwang Cui[3], Djeneba Dabitao[1], Mahamoudou Toure[1], Seydou Doumbia[1]

[1]University Clinical Research Center (UCRC) / University of Sciences, Techniques and Technologies of Bamako (USTTB), Mali, Bamako, Mali, [2]College of Agriculture and Biotechnology, China Agricultural University, Beijing 100193, China, Beijing, China, [3]Department of Internal Medicine, University of South Florida, Tampa, USA, Tampa, FL, United States

Seasonal malaria chemoprevention (SMC) was recommended by the Word Health Organization in 2012. The strategy involves monthly administration of the antimalarials sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) to all children aged under six years during the malaria season. Monitoring SMC efficacy to protect against clinical malaria requires a detectable concentration of AQ in the blood at least four weeks after treatment. However, rigorous and affordable laboratory methods to quantify AQ are lacking in malaria-endemic countries. This study aimed to validate a new ELISA-based method to reliably measure AQ and its metabolites. We also assessed the kinetic of AQ concentration from day 0 to day 28 after treatment with respect to infection status in Koulikoro, Mali. AQ concentration was measured among 37 children under 10 years who received SP+AQ for SMC and 15 children not treated with SP+AQ as a control group. At enrollment within the treated group, 15 children were parasite-negative by microscopy, 17 parasite-positive with a parasite density of <5000/µL, and 5 parasite-positive with a parasite density of ≥5000. A blood sample (2 mL) was collected from all participants on days 0, 4, 7, 14, 21, and 28 of treatment and used for AQ ELISA. Results show that the AQ concentration peaked on day 4 regardless of the infection status in the treated group. In contrast, AQ was barely detectable in the control group. The median AQ concentration varied between subgroups with 158.75 (9.2-734.16), 138.26 (21.45-224.16), 41.85 (30.71-106.22) ng/mL, respectively, in non-infected children, infected ones with parasite density of <5000, and those with parasite density of ≥5000. Using a mixed linear model, we found that the mean AQ concentration significantly increased by 121.43 ng/mL on day 4 and 64.57 ng/mL on day 7, compared to the AQ level at enrolment (p-values <0.05). A weak but significant negative correlation was found between parasitemia and AQ concentration (r= -0.26, p= 0.01). We demonstrated that a validated ELISA technique could be used to accurately assess compliance with SMC and treatment outcomes in children from malaria-endemic countries.

5376

USING DEATH AUDITS TO IMPROVE CLINICAL MANAGEMENT OF SEVERE MALARIA AND MAP KEY NEEDS TO REDUCE MORTALITY IN NORTHERN ANGOLA

Teresa Nobrega[1], David Sunda[1], Davista Abílio[2], Gabriel Wangama[2], José Franco Martins[3], Ana Direito[1], Sérgio Lopes[4]

[1]The Mentor Initiative, Luanda, Angola, [2]Provincial Health Department, Uige, Angola, [3]National Malaria Control Programme, Ministry of Health, Luanda, Angola, [4]The Mentor Initiative, Haywards Heath, United Kingdom

Malaria is still the leading cause of death and school and work absenteeism in Angola. Severe forms of malaria can occur if cases are not adequately and on time diagnosed and treated. Several factors concur to negative outcomes including health worker, health system, supply chain issues. The objective of this study was to assess malaria attributed deaths to understand root causes for death occurrence. A 5-year temporal analysis of malaria related lethality was conducted in Uige province. Death audits were undertaken across 12 districts by provincial supervisors using a structured NMCP approved tool. A total of 553 malaria attributed deaths in these districts were registered of which 92 were purposively targeted for audits from HF registering higher number of malaria attributed deaths. The audit included the review of patient files and cross-checking information from diagnosis, treatment and overall provision of care including management of coma, anaemia and other common adverse events. Over the last 5 years, under the implementation of Health for All Project, funded by US President Malaria Initiative, intrahospital lethality in hyperendemic Uige dropped from 0,3% to 0,1%. Death audit results pointed out that of the 92 audits conducted, 7 (16%) could not be attributed to malaria as there was no confirmation test. Of those confirmed for malaria, 82 (96%) died within 24h after admission in the HF. In 82 (96%) cases the national protocol was followed with administration of artesunate as the first line drug. Severe anaemia (Hb<5) was found in 25 cases (29%) of which 15 (60%) received a blood transfusion. 21 (25%) of the patients presented neurological dysfunction. The results indicate a high proportion of cases died within 24h after admission, showing disease presentation was already severe on arrival which may be caused by delayed health care seeking. Severe anaemia and neurologic dysfunction were present in at least a quarter of the deaths, which denotes the need for advance life support care in place to manage severe malaria related consequences. Death audits are an essential tool to understand quality of case management amongst severe cases of malaria.

MULTIPLEX LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (MLAMP) COUPLED TO CARTRIDGE BASED NUCLEIC ACID LATERAL FLOW IMMUNOASSAY (NALFIA) DEVICE AS A ONE POT DIAGNOSTIC PLATFORM FOR MALARIA

Nabil Royez, Ayesha Wijesinghe, Jack Burke-Gaffney, Hitendra Kumar, Claire Kamaliddin, Shoaib Ashraf, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

Asymptomatic malaria carriers contribute significantly to disease transmission especially individuals who remain undiagnosed. Malaria eradication can only be achieved by ultrasensitive detection of both symptomatic and asymptomatic low-level parasitemia. Current malaria diagnosis employs microscopy and rapid diagnostic tests which suffer low limit of detection and quality assurance challenges in endemic countries. Molecular methods like PCR are costly, labor-intensive, and time-consuming. To overcome these problems, we have devised a novel rapid molecular approach by exploiting Multiplex Loop-mediated Isothermal Amplification (MLAMP) and Nucleic Acid Lateral Flow Immunoassay (NALFIA) technologies. Target samples (n=30 positives, 30 negatives) from returning travelers with malaria were chosen for validation of the diagnostic platform. Previous studies have focused only on dual assay Plasmodium genus/P. falciparum (Pf). We used a triplex format Plasmodium genus, Pf, and P.Vivax (Pv) in this study. Briefly, test samples were added to the MLAMP master mix containing six primers of each set that specifically

recognize and amplify different Plasmodium/Pf/Pv in one-pot. Species-specific probes labeled with FAM, Hex, Texas Red, and Cy5 were designed to differentiate between Pan, Pf, Pv, and controls respectively. Following our newly designed "DipQuick" protocol for simple extraction, isothermal amplification occurs inside our engineered "White Lotus" device. Amplification was detected through the excitation of specific fluorescent probes. MLAMP products are then applied to the NALFIA device where the amplicons carrying different fluorophores are captured by specific antibodies coated on the strip. To avoid amplicon contamination, the whole assay occurs in a closed cartridge system, in which multiple bands are formed to visually differentiate among different Plasmodium species. Preliminary data demonstrate that different Plasmodium species were detected ~20 mins. MLAMP-NALFIA is a rapid and ultrasensitive portable low-cost assay for the species-specific detection of malaria to further progress elimination.

5378

MALARIA RAPID DIAGNOSTIC TESTS (RDTS) INTERPRETATION ACCURACY OF HEALTH WORKERS COMPARED TO ARTIFICIAL INTELLIGENCE (AI) AND PANEL READ IN KANO STATE, NIGERIA

Sasha Frade[1], **Shawna Cooper**[1], Sam Smedinghoff[1], David Hattery[1], Yongshao Ruan[1], Paul Isabelli[1], Nirmal Ravi[2], Barry Finette[3], Megan McLaughlin[3], Ezra Mount Finette[3], Lynn Metz[3]

[1]Audere, Seattle, WA, United States, [2]eHA Clinics, Kano, Nigeria, [3]ThinkMD, Burlington, VT, United States

One strategy found to decrease malaria prevalence and mortality rates is early diagnosis using rapid diagnostic tests (RDTs). Although RDTs are known for their cost effectiveness, speed of result, and ease of use - misadministration and misinterpretation errors remain a concern amongst healthcare workers (HWs). This study investigated whether RDT use could be paired with a mobile application to improve the accuracy of mRDT interpretations amongst Health Care Workers in Kano State, Nigeria. We also investigated future applicability of result digitization and automated interpretation using artificial intelligence (AI) algorithms. The analysis assessed the accuracy of RDT interpretations against a trained group of RDT readers (Panel Read) and artificial intelligence algorithms (AI). Assessments were completed for: (1) AI interpretation compared to a Panel Read interpretation, (2) HW interpretation compared to a Panel Read interpretation, (3) HW interpretation compared to an AI interpretation, and (4) the AI performance for faint positives. The analysis first determined the AI interpretation accuracy by comparing the AI interpretation to the ground truth of the Panel Read for 2,479 RDTs. The AI performed well, correctly interpreting positives 95.54% of the time and negatives 96.90% of the time. The Panel Read was then compared to the HW interpretation, finding agreement 97.54% of the time on positives and 92.28% on negatives. Interpretation accuracy of the HWs was then determined by comparing their interpretations to the AI, providing a real-world use case for AI, with 96.76% agreement on interpretation of positives and 94.50% agreement on negatives. Overall accuracy was determined using a weighted F1 score, yielding 96.4 for the AI compared to 95.3 for experienced, well-trained health workers. The AI performed even better than HWs on faint lines, identifying 14.1% more faint positives than HWs, indicating AI's strengths in elevating performance of humans when evaluating RDT results. Together the HW and AI are a good team to support HW decision making, and ensure accurate reporting.

5379

EVOLUTION OF PFHRP2 AND PFHRP3 DELETIONS IN EQUATORIAL GUINEE BETWEEN THE PRE AND POST RDT INTRODUCTION AND THE IMPACT OF PUBLIC HEALTH STRATEGIES ON THEIR EXPANSION

Irene Molina- de la Fuente[1], M. Andreína Pacheco[2], Luz García[3], Vicenta González[3], Matilde Riloha[4], Consuelo Oki[5], Policarpo Ncogo[5], Agustín Benito[6], Ananias A. Escalante[2], Pedro Berzosa[3]

[1]University of Alcalá, Madrid, Spain, [2]Institute of Genomics and Evolutionary Medicine (iGEM), Temple University, Philadelphia, PA, United States, [3]National Centre of Tropical Medicine - Institute of Health Carlos III, Madrid, Spain, [4]National Malaria Programme-Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, [5]Fundación Estatal Salud, Infancia y Bienestar Social FSP, Malabo, Equatorial Guinea, [6]National Centre for Tropical Medicine-Institute of Health Carlos III, Madrid, Spain

Prompt and accurate diagnosis, mainly based on Rapid Diagnostic Tests (RDT) across Africa, is part of public health strategies for malaria control. However, it has been threatened by false negatives in RDT. The main cause of false negatives are some deletions found in pfhrp2 and pfhrp3 genes, which encode proteins detected by Plasmodium falciparum - specific RDT. Understanding the dynamics of the emergence, selection, and spread of parasites with pfhrp2 and pfhrp3 deletions could give insightful information to predict RDT efficacy in future scenarios for malaria control. This study aims to assess the temporal evolution of deletions considering different epidemiological settings and the impact of RDT use. Samples from two different regions in Equatorial Guinea (West Central Africa), the Island Region, North Bioko Province, (with low prevalence and high use of RDT), and the Litoral Province located in the Continental Region (with high malaria prevalence and low RDT use) were included. In particular, the emergence of deletions has been studied using samples from 1999 - 2001 (pre - RDT period), and two groups from 2016 and 2019, after RDT introduction. Deletions in exon 1 and 2 of pfhrp2 and pfhrp3 and its flaking regions were genotyped, observing an increasing trend in deletion frequencies, especially in the low prevalence region (the Island Region) with high RDT use. Additionally, exon 2 of pfhrp2 and pfhrp3 were sequenced to analyse changes in genetic diversity, aminoacidic composition, and the frequency of major epitopes over time. Finally, population diversity and deletions-expansion characteristics were assessed using 7 neutral microsatellites. Overall, haplotype networks suggest that pfhrp2 and pfhrp3 deletions emerged multiple times in Equatorial Guinea. Our findings highlight the importance of molecular surveillance to assess the efficacy of RDTs in malaria control programs.

5380

SUPEROXIDE GENERATION AND REDOX CYCLING OF PRIMAQUINE METABOLITES ARE DRIVEN BY BILIVERDIN REDUCTASE B AND N-RIBOSYLDIHYDRONICOTINAMIDE: QUINONE REDUCTASE 2

Mitasha S. Palha[1], Eric A. Legenzov[1], Karolina Dziewulska[2], Paul Buehler[1], Derek R. Lamb[1], Robert Commons[3], **James C. Zimring**[2], Joseph P. Y. Kao[1]

[1]University of Maryland, Baltimore, MD, United States, [2]University of Virginia, Charlottesville, VA, United States, [3]Menzies School of Health Research, DArwin, Australia

Primaquine and tafenoquine are the only approved drugs for radical cure of Plasmodium vivax but can cause severe hemolysis from generation of reactive oxygen species (ROS) in patients with glucose-6-phosphate dehydrogenase deficiency (G6PDd). Primaquine is a prodrug, but small amounts of primaquine metabolites (PMs) generate large amounts of ROS through redox cycling. A PM receives an electron from a donor (e.g., NADH) to form a PM radical, which then transfers the electron to molecular oxygen (O2) to form superoxide (SO, O2• -), and in doing so, regenerates the PM that can undergo another redox cycle. However, many redox toxins do not cycle spontaneously, but require an enzymatic reductase to mediate the electron transfer. We characterized the redox cycling requirements of a major hemolytic PM, 5,6-primaquine-orthoquinone (5,6-POQ). SO

generation was measured by electron paramagnetic resonance (EPR) using a SO-specific spin probe. EPR detected only low levels of SO from 5,6-POQ incubated with common electron donors, NADH, NADPH, or N-ribosyldihydronicotinamide (NRH). However, robust SO generation was observed when either of the two most abundant quinone reductases from RBCs were added in the presence of their cofactors. Biliverdin reductase B (BLVRB) plus NADPH or N-ribosyldihydronicotinamide:quinone reductase 2 (NQO2) plus NRH accelerated SO generation by 6.3- and 13-fold, respectively. Specific inhibitors prevented SO generation for BLVRB (Phloxine B; $p < 0.0001$) or NQO2 (S29434; $p < 0.0001$). These findings identify two RBC reductases that are alone sufficient, in vitro, to reduce 5,6-POQ and promote redox cycling. These findings also have two translational implications. First, adding inhibitors of BLVRB and/or NQO2 to primaquine may mitigate hemolysis in G6PDd patients requiring treatment for relapsing malaria. Because primaquine is redox cycled in hepatocytes by cytochrome P450s, which is not expressed in RBCs, BLVRB and/or NQO2 inhibitors are not predicted to interfere with radical cure. Second, nutritional status may affect primaquine induced hemolysis in G6PDd patients, as NR, the precursor of NRH, is diet derived.

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Massachusetts Institute of Technology, Cambridge, MA, United States, [3]Columbia University Irving Medical Center, New York, NY, United States, [4]University of Dundee, Dundee, United Kingdom, [5]University of California, San Diego, La Jolla, CA, United States, [6]GlaxoSmithKline, Tres Cantos, Spain, [7]The Broad Institute, Cambridge, MA, United States, [8]Medicines for Malaria Venture, Geneva, Switzerland

Identifying how small molecules act to kill malaria parasites can lead to new "chemically validated" targets. By pressuring Plasmodium falciparum asexual blood stage parasites with three novel structurally unrelated antimalarial compounds (MMV665924, MMV019719 and MMV897615), and performing whole-genome sequence analysis on resistant parasite lines, we identify multiple mutations in the P. falciparum acyl-CoA synthetase (ACS) genes ACS10 (PF3D7_0525100) and ACS11 (PF3D7_1238800). Mutations in ACS10 showed either resistance to all compounds (M300I and F427L) or collateral sensitivity to another compound (A268D 10-times more susceptible to MMV019719, A268V 2-times more susceptible to MMV665924). Introduction of M300I mutation into wildtype parasites phenocopied the resistance phenotype of the selected line. ACS genes are highly polymorphic and surprisingly, the ACS10 M300I mutation identified here was present at 78% in a natural Malawi parasite population. A Malawian isolate containing the M300I polymorphism was five-fold more resistant to MMV665924 than a matched ACS10 wild type Malawi isolate. Conditional knock-down lines showed that ACS10 is essential in asexual growth in vitro and reduced ACS10 protein levels rendered parasites more susceptible. Thermal-shift assays followed by Mass-spectrometry identified that MMV897615 indeed shifted the thermal stability curve of ACS10 validating ACS10 as the likely target of these compounds. ACSs are enzymes that activate fatty acids scavenged from the host. Inhibition of ACS10 by MMV665924 or MMV897615 leads to a reduction in triacylglycerols and a buildup of its lipid precursors. On the other hand, while allelic replacement of mutations in ACS11 phenocopies the selected lines, conditional knockdown data demonstrate that ACS11 is not essential for asexual parasite growth, implying that ACS11 may be mediating resistance rather than being a direct target. While ACS10 is an attractive new drug target, natural occurring polymorphisms in field parasite populations might reduce the efficacy of these compounds.

5382

FIGHTING MALARIA WITH "IRRESISTIBLE" DRUGS

Laura M. Sanz[1], Clare Anderton[2], Pablo Castañeda[3], Jorge Fernandez[3], Maria Jose Lafuente[1], Gareth Lewis[2], Marisa Martinez[3], Raman Sharma[2], Francisco Javier Gamo[1]

[1]GSK Global Health Medicines R&D, Tres Cantos, Spain, [2]GSK R&D, Stevenage, United Kingdom, [3]GSK R&D, Tres Cantos, Spain

Malaria is a major global disease which is transmitted to humans through the bites of infected female mosquitoes. According to the last WHO Malaria report there were an estimated of 247 million cases with 619,000 deaths worldwide. Plasmodium falciparum is the species accountable for nearly 90% of these deaths. Children under 5 are particularly susceptible to malaria illness, infection and death. In addition, malaria has severe socioeconomic impact in endemic countries. In fact, approximately 25% of the endemic countries incomes are devoted to treating and minimizing the impact of this disease. With the actual emergence of resistance against all antimalarial treatments including the standard of care artemisinin-based combination therapies (ACTs), first in the Cambodia and Thai-Burmese border region but now spread to certain African regions, there is an urgency to develop novel combination therapies. New compounds with novel modes of action and potent activity against sensitive and resistant Plasmodium parasites, are urgently needed to withstand resistance issues. Among the new opportunities identified as result of GSK whole cell phenotypic screening, a novel pyrazine class of antimalarial with promising potential has been identified. As one of the most outstanding properties, this series has demonstrated an extremely low propensity to select resistant parasites in vitro. The capability of preventing the emergence of malarial resistance renders this molecule an "irresistible" profile and offers a unique opportunity as an additional tool for future novel antimalarial combination. Furthermore, the pyrazine molecule selected as preclinical candidate molecule displays an appropriate pharmacokinetic profile along with a rapid mechanism of action that support potential for single oral dose cure. This profile could increase adherence and improve treatment efficacy whereas contributing to hampering parasite resistance selection.

LEVERAGING RWANDA'S COMMUNITY HEALTH WORKERS TO CONDUCT A THERAPEUTIC EFFICACY STUDY IN AREAS OF DECLINING MALARIA TRANSMISSION

Noella Umulisa[1], Aline Uwimana[2], Katherine Wolf[3], Jean M. Harerimana[1], Celestin Ntirandeka[1], Naomi Lucchi[4], Kaendi Munguti[5], Beata Mukarugwiro[5], Jehan Ahmed[6], Aimable Mbituyumuremyi[2]

[1]U.S. President's Malaria Initiative Impact Malaria project, Kigali, Rwanda, [2]Malaria and Other Parasitic Diseases Division/Rwanda Biomedical Center, Kigali, Rwanda, [3]U.S. President's Malaria Initiative Impact Malaria project, Baltimore, MD, United States, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control, Kigali, Rwanda, [5]U.S. President's Malaria Initiative, USAID, Kigali, Rwanda, [6]U.S. President's Malaria Initiative Impact Malaria project, PSI, Washington, DC, United States

Regular monitoring of artemisinin-based combination therapies (ACTs) is important to promptly detect and respond to emerging antimalarial resistance. The last two therapeutic efficacy studies (TESs) in Rwanda conducted in 2013-2015 and 2018, showed an artemether-lumefantrine (AL) efficacy over the 90% WHO benchmark for treatment policy change. However, day 3 parasitemia levels exceeded 10% in two of the three study sites, a criterion for suspected artemisinin resistance. In June 2021, Rwanda began a follow-up TES evaluating AL, the first line treatment, and dihydroartemisinin-piperaquine (DP), the second line treatment, in three health centers (HCs): Masaka, Rukara and Bugarama. Six months into the study, only 9 (1.7%) and 39 (7.4%) participants were enrolled in Masaka and Bugarama, respectively, and none in Rukara. This was due

to a decline in malaria cases (~41% in 2021 compared to 2020), likely a result of the successful malaria control interventions in place. In addition, 55% of all malaria cases in Rwanda are currently diagnosed and treated at the community level with only a small percentage managed in the HCs. To encourage malaria patients to attend the study HCs, Rwanda developed a strategy to engage community health workers (CHWs) to enhance study recruitment. In addition, routine malaria data from 2020 to 2021 were analyzed to replace Rukara HC with Ngoma HC, in a higher burden area. Through meetings with local leaders, partners and the malaria program, and trainings, CHWs were encouraged to refer all malaria RDT positive cases to the study HCs. In total, 92 CHWs from 46 villages in Masaka, 194 from 97 villages in Bugarama, and 64 from 32 villages in Ngoma were trained on the study protocol. From October 2021 to January 2023, 358 of the 528 (68%) required participants were enrolled and 78% of these were referred by CHWs. Innovative enrollment strategies are key to conducting TES in areas of declining malaria transmission. In a country like Rwanda where over 50% of malaria management is at the community level, active involvement and collaboration with CHWs and local leaders is essential.

Prodiginines are a family of intriguing pyrrolylpyrromethene alkaloid natural products, produced by actinomycetes and other eubacteria. Recently, there has been an increase of interest in natural and synthetic prodiginines because they have shown a broad range of therapeutic applications. While a few natural prodiginines have been evaluated for antimalarial activities, synthetic prodiginines have not been explored until our recent investigations. The modes of action are unknown for these prodiginines and the unique structure along with their pan-sensitivity against a large panel of MDR malaria parasites suggest potential to discover a new drug target to combat malaria parasites. Over the past few years, our research has focused on the discovery and development of novel antimalarials from the natural sources and we have developed prodiginine natural products as novel antimalarials that are effective against multiple life-cycle stages of the malaria parasite. Our prodiginine scaffold is a unique chemotype as compared to existing antimalarials, and potentially operates by a novel mode of action. In this context, we present the detailed optimization and structure-activity relationships of the novel prodiginine chemotype.

5385

ACRIDONES AS NOVEL LIVER STAGE ACTIVE ANTIMALARIAL

Jane Kelly[1], Papireddy Kancharla[2], Rozalia Dodean[1], Yuexin Li[1], Patricia Lee[3], Diana Caridha[3], Michael Madejczyk[3], Monica Martin[3], Xiannu Jin[3], Kristina Pannone[3], Mara Kreishman-Deitrick[3], Chad Black[3], Qigui Li[3], Christina Nolan[3], Roland Cooper[4], Michael Riscoe[1], Brandon Pybus[3], Alison Roth[3]

The global impact of malaria remains staggering despite extensive efforts to eradicate the disease. The challenges for a sustainable elimination include the failing effectiveness of front-line artemisinin-based combination therapy (ACT) due to emerging resistance and safety concerns associated with limited radical cure options for relapsing Plasmodium vivax. There is an urgent need for novel, effective, affordable and safe antimalarial drugs to overcome drug resistance, and ideally, such agents would be efficacious against both blood stage and liver stage malaria infections. We have developed a novel antimalarial acridone chemotype with dual stage efficacy against both liver stage and blood stage malaria, as well as single-dose cure ability and potential to prevent relapsing infection. Our novel acridone chemotype represents a broad-spectrum approach with potential to vanquish many challenges.

Relapsing malaria caused by Plasmodium vivax causes substantial morbidity. Currently, primaquine is the only available antimalarial to prevent relapses in South Asia, however its optimal regimen remains unclear. A systematic review identified P. vivax clinical efficacy studies published between Jan 1, 2000, and August 23, 2021. Available individual patient data were pooled using standardised methods. The cumulative risks of recurrence between days 7 and 42, and days 7 and 180 were assessed

by Kaplan-Meier methods with the effect of primaquine total mg/kg dose and treatment duration on rate of P. vivax recurrence investigated by Cox regression with random effects for study site. The number of patients with a >25% drop in haemoglobin to <7 g/dL, or an absolute drop of >5 g/dL between day 1-14 were categorised by primaquine daily mg/kg dose. The presence of vomiting, diarrhoea or anorexia following primaquine were assessed as a composite endpoint. Of 17 eligible studies, data were available from 7 studies including 791 patients from 4 countries. The cumulative risk of recurrence at day 180 was 61.1% (95% CI 42.2-80.4; 201 patients followed; 25 recurrences) after treatment without primaquine, 28.8% (95% CI 8.2-74.1; 398 patients; 4 recurrences) following low total dose primaquine (2-<5 mg/kg) and 0% (96 patients; 0 recurrences) following high total dose primaquine (≥5 mg/kg). After controlling for confounders, the rate of first recurrence between days 7 and 42 was reduced following treatment with low total dose primaquine compared to treatment without primaquine (adjusted hazard ratio: 0.4 (95% CI 0.1-2.8); no recurrences were observed following high total dose primaquine. No patients had a >25% drop in haemoglobin to<7g/dL. No data were available to assess gastrointestinal tolerability. Treatment with primaquine led to a marked decrease in the risk of P. vivax recurrences following low (~3.5 mg/kg) and high (~7 mg/kg) total dose primaquine regimens, with no reported severe haemolytic events. However, few data were available to compare efficacy of different primaquine regimen with prolonged follow up.

EFFICACY OF THREE ARTEMISININ-BASED COMBINATIONS FOR THE TREATMENT OF UNCOMPLICATED MALARIA IN CHILDREN IN BURKINA FASO

Adama Gansané[1], Siaka Debe[1], Moussa Lingani[2], Casimir Tarama[1], Salif Sombie[1], Rene Kinda[1], Adama Ganou[1], Farida Tiendrebeogo[1], Halidou Tinto[2], Gauthier Tougri[3], Charlotte Eddis[4], Jehan Ahmed[4], Leah F. Moriarty[5], Innocent Valea[2]

[1]Centre national de recherche et de formation sur le paludisme, Ouagadougou, Burkina Faso, [2]Unité de Recherche Clinique de Nanoro, Nanoro, Burkina Faso, [3]Programme national de lutte contre le paludisme, Ouagadougou, Burkina Faso, [4]PMI Impact Malaria, Washington, DC, United States, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States

The World Health Organization recommends regularly monitoring the efficacy of artemisinin-based combination therapy (ACT), a critical tool in the fight against malaria. This study evaluated the efficacy of three ACTs recommended to treat uncomplicated P. falciparum malaria in Burkina Faso in three sites across different epidemiological zones of malaria: Niangoloko, Nanoro, and Gourcy. This was a three-arm randomized controlled trial to assess the efficacy of artemether-lumefantrine (AL), dihydroartemisinin-piperaquine (DP), and artesunate-pyronaridine (As-Pyr) in children aged 6 months to 12 years old following supervised treatment. The primary outcomes of the study were uncorrected and PCR-corrected efficacies at day 28 for AL and day 42 for DP and As-Pyr. Day-7 lumefantrine concentrations for the AL arm were measured. We enrolled 1080 children:180 in the AL arm, 90 in the DP arm, and 90 in the As-Pyr arm per site. PCR-uncorrected 28-day efficacy in the AL arm was 64.7% [95% confidence interval (CI) 57.1-71.1], 64.0% [95% CI 56.4-70.6] and 56.7% [95% CI 49.1-63.6] in Gourcy, Niangoloko, and Nanoro. PCR-uncorrected 42-day efficacy in the DP arm was 86.7% [95% CI 77.3-92.4], 88.0% [95% CI 78.8-93.3] and 89.9% [95% CI 81.5-94.6] in Gourcy, Niangoloko and Nanoro. PCR-uncorrected 42-day efficacy in the As-Pyr arm was 64.6% [95% CI 53.0-74.0], 70.9% [95% CI 60.1-79.3] and 54.8% [95% CI 43.5-64.7] in Gourcy, Niangoloko and Nanoro. Median day-7 lumefantrine concentrations were similar across sites and end-point classification. The day-3 positivity rate was null in all arms in Nanoro, in the DP and AS-Pyr arms in Gourcy, and in the DP arm in Niangoloko. The day-3 positivity rate was 1.1% in the AL arm in Niangoloko and Gourcy and 1.2% in the As-Pyr arm in Niangoloko. The study results show evidence of high rates of PCR-uncorrected treatment failures in the AL and ASPY arms. The low uncorrected efficacy in the AL arm is consistent with previous studies. PCR correction is under way. These findings raise concerns about the most appropriate drug policy in Burkina Faso.

5388

EXPLORING DIMETHYL FUMARATE AS AN ADJUNCTIVE THERAPY FOR CEREBRAL MALARIA IN EXPERIMENTAL CEREBRAL MALARIA MODEL

Cheryl Sachdeva[1], Tarun Keswani[1], Akua Mensah[2], Min-Hui Cui[1], Craig Branch[1], Johanna P. Daily[1]

[1]Albert Einstein College of Medicine, Bronx, NY, United States, [2]CUNY Lehman College, Bronx, NY, United States

Approximately 1% of Plasmodium falciparum infected-children develop cerebral malaria (CM), which presents as a coma and is characterized by cerebral microvascular parasite sequestration. High rates of mortality and long-term neurocognitive impairment can occur in survivors despite potent antimalarial therapy. Adjunctive therapy is needed to improve CM outcomes. Our previous studies demonstrated the association of upregulation of transcription factor, Nrf2 in children with CM who had good clinical outcomes. Nrf2 modulates antioxidant and anti-inflammatory pathways, which may impact the pathophysiology of CM. Dimethyl fumarate (DMF) upregulates the Nrf2 pathway and is used to prevent relapses of multiple sclerosis. We assessed the potential of DMF in the experimental cerebral malaria model (ECM). We examined the effects of DMF on survival, neuro-cognition and blood brain barrier permeability in C57BL6 female mice infected with P. berghei ANKA using state-of-the-art techniques. DMF significantly increased survival in mice during ECM ($p = 0.0002$). No difference was observed in total body or brain parasite sequestration, using in vivo imaging in mice infected with P. berghei ANKA GFP-Luciferase strain, suggesting that the protective property of DMF is not due to an antiparasitic effect. In ECM mice treated with DMF, we also observed improvement of neurocognitive function during the course of infection using the rapid murine coma and behavior scale. Furthermore, DMF reduced the blood-brain barrier disruption in ECM using the Evans blue extravasation assay on day 6 post infection ($p = 0.01$). We also examined the effect of DMF on brain volume in ECM using magnetic resonance imaging. DMF did not impact the increased brain volume which occurs during ECM. Taken together, this data supports DMF, an FDA approved drug, as a potential adjunctive therapy in CM as it increases survival and reduces the neurological decline in ECM.

METABOLISM OF TAFENOQUINE AND TAFENOQUINE DRUG COMBINATIONS IN LIVER CELL CULTURES

Geoff W. Birrell, Anthony Davies, Karin Van Breda, Michael D. Edstein, George D. Shanks

ADF Malaria and Infectious Disease Institute, Brisbane, Australia

Antimalarial drugs of the 8-aminoquinoline class (pamaquine, primaquine (PQ), and tafenoquine (TQ)) have been the basis of malaria chemotherapy to prevent relapses and block transmission for nearly a century. Despite their wide-spread use, their metabolism and mechanism of action are still poorly understood. The importance of metabolism was suggested by an extensive 8-aminoquinoline testing program conducted by the US Army which found that 8-aminoquinolines without redox activity were unable to inactivate the latent residual parasites in the liver (hypnozoites) responsible for relapsing malaria. The precise mechanism of action of 8-aminoquinolines has been a subject of interest and conjecture for many years. It is known that monoamine oxidase (MAO) and cytochrome P450 2D6 (CYP2D6) convert PQ to the inactive carboxyprimaquine. Hydroxylated-PQ metabolites (OH-PQm) are responsible for efficacy against liver and sexual transmission stages of Plasmodium falciparum. The major CYP2D6 metabolite, formed by degradation of the unstable 5-hydroxy-PQ was found to be 5,6-OQ (5,6-orthoquinone). We have observed, quantified and partly characterised the hydroxylated metabolite of TQ (5,6-OQTQ) that is a marker of oxidative metabolism. Using high resolution accurate mass spectrometry and sophisticated compound structure elucidation software we have identified

the production of 5,6-OQTQ and other stable TQ metabolites in response to TQ alone and drug combinations of TQ over time. In addition, we have used western blotting to demonstrate CYP1A1 enzyme level modulation by TQ and drug combinations of TQ. The CYP1A1 transcript has previously been shown to be modulated by TQ. Our results may help explain the reduced therapeutic efficacy of TQ when combined with artemisinin combination therapies as well as to identify suitable TQ partner drugs in the treatment and prevention (i.e., post exposure prophylaxis) of P. vivax infections.

PREDICTION OF ADENYLOSUCCINATE LYASE 3D STRUCTURE A PROMISING THERAPEUTIC TARGET IN PLASMODIUM FALCIPARUM AND ITS POTENTIAL INHIBITORS FROM AFRICAN NATURAL COMPOUND DATABASES

Mamadou Sangare

African Center of Excellence in Bioinformatics (ACE-B)/USTTB,Mali, Bamako, Mali

The emergence and spread of resistant strains of Plasmodium falciparum constitute the main obstacles for the control of malaria. So, the discovery of new drugs is still urgent and requires continuous effort to identify new therapeutic targets. In this study we present P. falciparum AdenyloSuccinate lyase (Pf ADSL) as a highly promising therapeutic target. This important enzyme is involved in de novo purine biosynthetic pathway, unique in P. falciparum, which results to the formation of adenosine monophosphate (AMP). Because of its role in purine metabolism, this enzyme appears as a promising drug target in P. falciparum.We aimed to construct the 3D structure of Pf ADSL and predict its potential inhibitors from three databases of natural products.The 3D structure of Pf ADSL was modeled using ALphafold server, and natural compounds were extracted from AFRODB, SANCDB, ANPDB. ADMET (Absorption, Distribution, Metabolism, Excretion and Toxicity) predictions were performed using SwissADME, and virtual screening was performed with AutoDock-vina. After virtual screening, the ten (10) compounds with the best binding energies, good ADMET properties and also demonstrated the best results in protein-ligand interactions were selected. The binding energies were ranged between -9.6 and -8. kcal/mol and the selected compounds can provide a basis for invitro studies.The obtained results therefore need to be validated experimentally to confirm their inhibitory activities.

[1]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [2]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Department of Clinical Research, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Groupe de Recherche Action en Santé (GRAS), Ouagadougou, Burkina Faso, [5]Department of Infection Biology, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Department of Non-Communicable Disease Epidemiology, Faculty of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]Quantitative Engineering Design (QED.ai), Warsaw, Poland

It is unknown whether malaria or malaria treatment affects COVID-19 severity, SARS-CoV-2 viral load or duration of shedding. Several antimalarials exhibit antiviral activity against SARSCoV-2 and have been suggested as potential therapeutic candidates for COVID-19, particularly pyronaridine-artesunate (PA). A previous trial in COVID-19 patients without malaria showed that PA enhanced viral clearance compared to placebo. We conducted an open-label randomised trial comparing standard 3-day treatment with PA and artemether-lumefantrine (AL) in newly diagnosed SARS-CoV-2 infected patients aged >=6 months with rapid diagnostic test or microscopy-confirmed non-severe malaria in Kenya and Burkina Faso. SARS-CoV-2 was assessed by RT-PCR on days 3, 7 (primary endpoint), 14 & 28 and symptom resolution daily for 14 days by FLUPRO+. Complete case analysis was conducted using log-binomial regression for binary outcomes, cox-regression for time-to-event outcomes and Poisson regression for count outcomes, adjusted for age, disease severity and viral load at enrolment. From February 2021 to January 2022, 143 participants were enrolled and 133 (AL:68, PA:65) with confirmed SARS-CoV-2 RT-PCR or positive serology/seroconversion contributed to the mITT analysis; median age 20 yrs (IQR 13-38). The baseline characteristics were comparable. Viral clearance by day 7 was slower with PA (adjusted hazard ratio [aHR]:0.62, 95% confidence interval 0.43-0.89, p=0.010) and median (IQR) SARS-CoV-2 viral load on day-7 was higher (AL:1337 [204-7519] vs PA:12,881 [272-46,624], p=0.080). The proportion SARS-CoV-2 by day 7 was AL:58% (38/66) vs PA:48% (29/61) (RR=0.81, 0.58-1.12, p=0.20), and by day 14 AL:94% (62/66) vs PA:84% (51/61) (RR=0.87, 0.77-0.99, p=0.028). The time to symptoms clearance was similar (HR=1.01, 0.69-1.48, p>0.90). There were 8 serious adverse events (AL:3, PA:5), including 3 hospitalisations (AL:2, PA:1) and 2 deaths (AL:1, PA:1). PA in COVID-19 patients co-infected with malaria was associated with slower viral clearance than standard treatment with AL and with similar symptom resolution.

5392

LEVERAGING COMMUNITY OWNED RESOURCE PERSONS (CORPS) TO REACH THE UNDERSERVED POPULATION THROUGH INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM) TO FIGHT MALARIA IN TANZANIA

Onesmo Mwegoha[1], Goodluck Tesha[2], Sijenunu Aaron[1], Abdallah Lusasi[1], Samwel Lazaro[1], Hassani Mwaga[1], Daniel Mbwambo[1], Katherine Wolf[3]

[1]National Malaria Control Program, Ministry of Health, Dodoma, Tanzania, United Republic of, [2]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego, Baltimore, MD, United States

Malaria modeling in Tanzania demonstrates that case management (CM) should target ≥85% malaria cases appropriately managed in high malaria transmission areas to increase CM effectiveness and decrease transmission. Tanzania's policy against the use of community volunteers for CM creates a gap at the community level, which is addressed through the deployment of Community Owned Resource Persons (CORPs). CORPs are qualified medical personnel at the community who are either retired or unemployed whom the National Malaria Control Program (NMCP) utilizes to promote the early recognition, prompt testing and appropriate treatment of malaria among all age groups in areas with limited access to facility-based health care providers. CORPs were mapped in 10 high malaria councils to establish an equitable and efficient system for delivery of community malaria case management services. The mapped villages had high malaria risk, were hard to reach as well as overstretched health services. The service operates within the routine delivery system by using current logistic and M&E frameworks. Sensitization was done with regional and council health management teams, and CORPs were trained. 104 (33%) CORPs were mapped in 311 villages that also have 434 Community Health Workers (CHWs). Between June and December 2022, CORPs attended to 35,409 patients and tested 33,030 (93.3 %) for malaria. Among them, 10,631 (32%) had confirmed malaria. Community level diagnosis accounts for 5% of national malaria cases and 16% in those Councils during the reporting

period. Community malaria CM promotes the early recognition, prompt testing and appropriate treatment of malaria among all age groups in areas with limited access to facility-based health care providers. Following the experience and lessons learned, the Ministry of Health through the NMCP plans to: 1) review protocol for iCCM implementation to address the challenges (eg. low numbers of CORPS per village); 2) advocate for using CHWs in place of CORPs for the sustainability of the intervention; and 3) review data collection and support supervision tools to address challenges.

5393

MALARIA AND THE INTERMITTENT PREVENTATIVE TREATMENT FOR FOREST-GOERS IN CAMBODIA: PRELIMINARY RESULTS AND LESSONS LEARNED

Siv Sovannaroth[1], Bunmeng Chhun[2], Rafael Jairah Jr. Matoy[2], Vichka Khy[2], Elijah Filip[2], Céline Christiansen-Jucht[3], Giulia Manzoni[3], Luciano Tuseo[3], Huy Rekol[1]

[1]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [2]Clinton Health Access Initiative, Phnom Penh, Cambodia, [3]World Health Organization, Phnom Penh, Cambodia

Malaria risk in Cambodia is highest in forest and forest fringe areas and linked to forest-goers. To address this challenge, the National Center for Parasitology, Entomology and Malaria Control (CNM), alongside the World Health Organization (WHO), began implementing "Last Mile Elimination" (LME) in 2021 - an innovative collection of interventions which includes providing intermittent preventative treatment for forest goers (IPTf) to prevent malaria infection. In each of the 117 LME villages, a census was conducted to identify male forest-goers between the ages of 15 and 49 who would be eligible for IPTf. Once identified, village malaria workers (VMWs) went door-to-door weekly to distribute IPTf to those planning to go to the forest in the following 30 days. Based on the preliminary findings of the initial implementation, the rate of this population taking IPTf has not surpassed 50% since the start of the program. Several contributing factors have been identified, including concerns about side effects and their impact on an individual's ability to work and the fact that some forest-goers were engaged in illegal forest activities and were reluctant to disclose their forest-going habits. CNM has responded to these challenges by adapting its approach to IPTf, yielding important lessons learned the application of prophylactic approaches. For example, due to reports of persistent side effects, CNM shifted from artesunate-mefloquine to artesunate-pyronaridine starting in August 2022. CNM has also incentivized treatment completion to ensure forest-goers are fully protected from getting malaria. Despite the low uptake of IPTf, LME villages in Kampong Speu and Kratie implementing the full package of interventions have seen P. falciparum and mixed infections decrease by 82% over the last two years and there are ongoing analyses to ascertain whether this decrease was due, in part, to the distribution of IPTf. As Cambodia approaches elimination, documenting and sharing lessons learned and identifying which programs are truly accelerating elimination will be instrumental in aiding both Cambodia and the region in reaching their elimination targets.

PLANT-DERIVED ADJUVANTS PROVIDE A PATH TO THWARTING EMERGING DRUG-RESISTANT MALARIA

Pooja Rani Mina

Bioprospection and Product Development Division, CSIR- Central Institute of Medicinal and Aromatic Plants, Lucknow, India

Plasmodium falciparum's drug resistance has become a significant issue in recent decades. Humans developed drug resistance to most antimalarial drugs, which caused severe side effects and failed malaria elimination programs. Hence, there is a need to investigate chemotherapeutic agents with low cost and causing minimal toxicity for the treatment of malaria. Combination therapy is a more emerging trend to control drug-resistant malaria. Plant-derived products are highly accessible and available and can be used as partner drugs with recommended ACTs and other clinically used drugs. Considering the above problems, a systematic study was conducted to search for reported plant-based adjuvants and combination therapy. Identifying practical, synergistic/additive drug combinations could improve drug-resistant malaria control. This review critically appraises the available evidence regarding plant-derived adjuvants to combat the problem of drug resistance in malaria. My presentation will highlight my previous work with current drug scenario available in past years for plant-derived adjuvants for combination therapy to combat drug resistance in malaria.

5395

SPILLOVER EFFECTS OF REACTIVE, FOCAL MALARIA ELIMINATION INTERVENTIONS IN NAMIBIA

Jade Benjamin-Chung[1], Haodong Li[2], Adam Bennett[3], Roly Gosling[4], Davis Mumbengegwi[5], Immo Kleinschmidt[6], Alan Hubbard[2], Mark van der Laan[2], Michelle S. Hsiang[4]

[1]Stanford University, Stanford, CA, United States, [2]University of California, Berkeley, Berkeley, CA, United States, [3]PATH, Seattle, WA, United States, [4]University of California, San Francisco, San Francisco, CA, United States, [5]University of Namibia, Windhoek, Namibia, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

A recent factorial cluster-randomized trial in Zambezi region, Namibia found that interventions targeted within 500m of index cases reduced malaria incidence (NCT02610400). To investigate whether interventions also reduced incidence in nearby areas, we measured spillover effects among untreated individuals within 500m and up to 1km from index cases. The trial randomized 56 clusters to: 1) reactive case detection (RACD) with rapid diagnostic testing and treatment with artemether-lumefantrine (AL) and single-dose primaquine, 2) reactive focal mass drug administration (rfMDA) with presumptive treatment with AL, 3) rfMDA + reactive focal indoor residual spraying (rfIRS) with indoor residual spraying using pirimiphos-methyl, and 4) rfMDA + rfIRS. Our primary outcome was the cumulative incidence of locally acquired Pf malaria in untreated individuals up to 1km from index cases. We defined spillover effects as cumulative incidence ratios (CIRs) for treatment contrasts based on the parasite reservoir targeted: 1) human reservoir (rfMDA vs. RACD); 2) mosquito reservoir (rfIRS vs. no rfIRS); and 3) human & mosquito reservoir (rfMDA + rfIRS vs. RACD). We estimated unadjusted CIRs and adjusted CIRs accounting for statistical interference between outcomes of nearby untreated individuals in different study clusters using hierarchical targeted maximum likelihood estimation. For all treatment contrasts, cumulative incidence in untreated individuals was lower in the treatment vs. comparison arms. Unadjusted CIRs were 0.85 (95% CI 0.75, 0.95) for any rfMDA vs. RACD, was 0.67 (0.60, 0.75) for rfIRS vs. no rfIRS, and 0.57 (0.48, 0.67) for rfMDA + rfIRS vs. RACD. Using TMLE and accounting for interference, CIRs were 0.78 (0.26, 2.37) for rfMDA vs. RACD, 0.93 (0.45, 1.90) for rfIRS vs. no rfIRS, and 0.60 (0.34, 1.05) for rfMDA + rfIRS vs. RACD. Overall, our findings suggest that targeted interventions produced spillover effects and may hold promise for malaria elimination. Measuring spillover effects can inform a precision public health approach using focal interventions to reduce malaria in and near hot spots in low transmission settings.

5396

EFFECTS OF METEOROLOGICAL FACTORS AND ELEVATION ON MALARIA TRANSMISSION IN ELIMINATION TARGETED DISTRICT OF ETHIOPIA

Desalegn Dabaro Dangiso[1], Zewdie Birhanu[2], Abiyot Negash[3], Dawit Hawaria[4], Delenasaw Yewhalaw[3]

[1]Yirgalem Hospital Medical College, Yirgalem, Ethiopia, [2]imma University, Jimma, Ethiopia, [3]Jimma University, Jimma, Ethiopia, [4]Hawassa University, Hawassa, Ethiopia

Malaria remains a significant public health issue in Ethiopia despite impressive progress made toward the 2030 targets of eliminating the disease. Several factors, most notably climate change, and related environmental factors have been challenging the progress. This study aimed to ascertain the transmission dynamics of malaria and associated factors in the elimination-targeted districts in the country. Malaria morbidity and meteorological data recorded from 2010 to 2017 were obtained from the

district's health facilities and the national meteorology agency, respectively. A community-based asymptomatic malaria survey was also conducted from April to May 2021, using rapid diagnostic test and light microscopy. A total of 135,607 malaria suspects were diagnosed using RDT and microscopy over the last 8 years, of which 29,554 (21.8%) were confirmed positive cases. Plasmodium falciparum, P. vivax, and mixed infection accounting for 56.3 %, 38.4 %, and 5.2 %, respectively. A time series plot showed a marked decline in the disease. In a negative binomial regression, the transmission season, rainfall, temperature, elevation, and the patient's sex and age were predictors of occurrence. The monthly incidence was predicted to oscillate about 88 cases in 2030 by an ARIMA (2, 1, 2), the best-fit model for point prediction. Asymptomatic malaria was prevalent (6.1%), and the use of bed nets, prior travel experiences, and window placement all significantly increased the risk of infection. The prediction models revealed that the elimination target would not be accomplished despite a significant decline in malaria morbidity in the examined years. The rising incidence of asymptomatic malaria in the community supports the model's forecast that the targeted elimination objective would not be achieved. Thus, the intensification of existing interventions by considering community mobility patterns and housing conditions might help in achieving the elimination goal.

5397

PRESENT STATUS OF THE PRIVATE SECTOR ENGAGEMENT IN MALARIA CASE MANAGEMENT IN BANGLADESH

Mohammad Sharif Hossain[1], Md Ekramul Haque[2], Mohammad Jahangir Alam[3], Ching Swe Phru[1], Md Nazmul Islam[4], Md Moshiqur Rahaman[2], Md. Mushfiqur Rahman[5], Anupama Hazarika[3], Mohammad Shafiul Alam[1]

[1]icddr,b, Dhaka, Bangladesh, [2]National Malaria Elimination Programme (NMEP), Directorate General of Health Services (DGHS), Dhaka, Bangladesh, [3]World Health Organization Bangladesh Office, Dhaka, Bangladesh, [4]Communicable Diseases Control Unit, Directorate General of Health Services (DGHS), Dhaka, Bangladesh, [5]BRAC, Dhaka, Bangladesh

Bangladesh has achieved remarkable progress in malaria control and sets a target to become malaria-free by 2030. Currently, private sector involvement is limited to, partner NGOs in the NMEP platform. We conducted this study to understand the role of the for-profit private sector in malaria case management not partnering with NMEP in Bangladesh. Based on the endemicity and strategic priorities, we purposively selected 15 Upazilas for this study. Among them, eight were from high transmission districts (control area), six were from low transmission districts (endemic area) and one from non-endemic districts that have borders with high transmission districts. We have listed and enrolled all the for-profit private sectors in those selected upazilas that have some capacity for malaria case management. A structured questionnaire was developed and used with the advice of the expert panel members. Between August to September 2022, a total of 104 health facilities were enrolled from 15 upazilas. More than half (54.8%) of health facilities were consulted & diagnostic centers followed by private clinics (18.3%) and drug stores with malaria diagnostic facilities (13.5%). Overall, 80.8% of facilities provided malaria testing while only 18.3% provided treatment services. Most of the health facilities in the control areas had facilities for malaria testing by RDT (77.7%), however, it was quite higher (95.0%) in endemic areas than control area. The price of RDT test varies widely from 50-1000 Bangladeshi Taka in different areas. Overall, 42.3% of health facilities reported malaria cases to the health authorities, however, this reporting was much lower in control areas (21.9%) than in the endemic areas (56.1%). Among the providers, 62.9% indicated willingness to work with the NMEP platform. Our study concludes that the for-profit private sector is somehow engaged in malaria case management but their contribution is not recognized. There is interest among the providers to work under the NMEP platform. However, there is an urgent need for a strategy to incorporate them into the nest of the NMEP surveillance systems.

5398

DETERMINANTS OF HIGH NON-REDUCING MALARIA ADMISSION RATES IN GHANA: AN AUDIT OF MALARIA ADMISSIONS IN 13 HEALTH FACILITIES WITH HIGHEST RATES IN 2021

Tracy Hanson[1], Paul Boateng[2], George Adu Asumah[2], Alex Asamoah[2], Mildred Komey[2], Ferguson Duvor[2], Joel Balbaare Naa[2], Nana Yaw Peprah[2], Kezia Malm[2]

[1]University of Ghana Medical school, Accra, Ghana, [2]National Malaria Elimination Programme, Accra, Ghana

Despite reductions in malaria prevalence in Ghana over the years, malaria admissions have remained stagnant, with a recent rise from 120 to 129 per 10,000 population between 2021 and 2022. This study was conducted to identify factors associated with the high unremitting admission rates. A cross-sectional study was conducted in September 2022. January to June 2022 malaria admissions data from the national Health Information Management System (HIMS) for 13 facilities were verified using source data. Also, medical records of 394 clients admitted for malaria (severe malaria) were reviewed, and data abstracted. Data was analyzed using Stata 16.0 into frequencies, proportions and means. Logistic regression was performed to determine association between malaria admission and explanatory variables. P-value <0.05 at 95% confidence interval was judged significant. Nearly half 6/13 (46%) of the facilities were privately owned. Significant data variation was noticed in 33% of the facilities (4/12), with faith-based health facilities and those using only paper-based data management systems more likely to observe significant variations. Fifty-one percent of cases were female, and 42.2% less than 10 years. Over 54% (215/394) of cases did not meet the WHO criteria for severe malaria, and among those meeting the criteria, 54.8% (98/179) had other severe comorbidities warranting admission by themselves. Significant associations were found between facility type, referral status, previous surgery, artemisinin-based combination therapy (ACT)after parenteral antimalarial and timeliness factors; and admission due to severe malaria ($p<0.05$). Eighty-nine percentof cases were tested for malaria, 18.0 % triaged, 96.7% received parenteral antimalarial for at least 24 hours, 86.4% prescribed full-course ACT after parenteral treatment and 54.5% scheduled for follow-up visit. Improvements are needed in quality of data validation meetings, application of WHO criteria for severe malaria, documentation, patient triaging and follow-up scheduling. Admission reporting forms need revision to distinguish severe from uncomplicated malaria.

5399

FORMULATION OF G6PD HEMOGLOBIN CONTROL FOR POINT-OF-CARE G6PD DIAGNOSTICS

Sampa Pal, Nerie Roa, Maria Kahn, Greg Bizilj, Manjari Lal, Gonzalo J. Domingo

PATH, Seattle, WA, United States

Radical cure of Plasmodium vivax malaria requires glucose-6-phosphate dehydrogenase (G6PD) testing. A significant gap for the implementation of point-of-care (POC) G6PD testing is the availability of reagents to support quality control (QC) of G6PD products along the supply chain from the manufacturer to the end user. Key attributes to the utility of these reagents are stability and unitized packaging. Although reagents and systems exist to support QC of laboratory screening tests for G6PD, they are not formulated or packaged adequately to support programmatic quality assurance (QA) programs for POC G6PD tests. PATH has developed a G6PD-hemoglobin combined control reagent that can be used in POC settings. To represent high or normal G6PD concentration, human recombinant G6PD was used for spiking whole blood in K2EDTA, whereas low or deficient G6PD was created with contrived whole blood sample. Prior to lyophilization, a protective formulation was mixed in the blood sample to protect the G6PD enzyme activity against degradation from denaturation. Formulated blood samples were aliquoted into individual single-use tubes for lyophilization. Post lyophilization, the freeze-dried reagents were placed in individual packs with desiccants and stored at different temperatures for a one-year stability

study. Reference assays for G6PD activity and hemoglobin concentration were used to determine the stability of the G6PD-hemoglobin controls. Lyophilized G6PD-hemoglobin controls in both normal and deficient levels are stable for at least 365 days when stored at 2°C-8°C. The reconstituted control in the liquid format is stable for 3 hours at ambient temperature. The formulation of combined G6PD-hemoglobin controls with high and low G6PD enzyme activity with yearlong stability will support a framework for a sustainable QC/QA system at country level to support robust point-of-care G6PD testing for P. vivax radical cure.

INVESTIGATING THE IMPACT OF LARVICIDING AS A SUPPLEMENTARY MALARIA VECTOR CONTROL TOOL IN RURAL SOUTH EASTERN TANZANIA: A SIMULATION STUDY

Gloria Salome Gabriel Shirima[1], Gerald Kiwelu[2], Ismail Nambunga[2], Samson Kiware[2]

[1]Nelson Mandela African Institution of Science and Technology, Arusha, Tanzania, United Republic of, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of

Despite tremendous gains in reducing the malaria burden due to the massive use of insecticide-treated nets (ITNs) and indoor residual spraying (IRS), transmission continues in most of sub-Saharan Africa. Rufiji district located in rural southeastern Tanzania, still has malaria transmission occurring despite high ITN coverage (80 -85%), which may be explained by the evolution of insecticide resistance and behavioral changes in malaria vectors. Therefore, there is an urgent need for additional interventions to complement ITN use. To investigate the potential impact of larviciding in different scenarios and coverage levels, a mathematical model, Vector Control Optimization Model was adapted and simulated with 80% ITN coverage as a baseline. To evaluate the effect of the application of larviciding on the mortality rate of An. gambiae, matured and immature mosquitoes were collected in two phases, before (2016-2017) and after (2019-2021) larviciding application. The entomological inoculation rates (EIR), reproduction number (R0) and biting rate were used as the primary outcome measures during the simulation. For the period of 1 year, larviciding was predicted to reduce EIR by 76.43% more than when only ITN was used, took over from 42 down to 9.9, Additionally, deploying larviciding together with ITNs was predicted to have a large impact, as it was estimated to reduce mosquito biting rate (approximately 60%) relative to the scenario without larviciding. Sensitivity analysis over a range of likely values for the biting rate, mosquito lifespan, and mosquito carrying capacity shows comparable the estimated impact between scenarios. This indicates that the predicted impact of larviciding is robust to uncertainty in model parameters and assumptions. The application of larviciding has practical challenges such as hardship in attaining high coverage but gives an assurance to vector control especially targeting the spreading An. Stephensi. This study supports larviciding as a successful strategy that policymakers and public health professionals, like the NMCP, may use to control malaria vectors based on WHO application recommendations.

5401

IMPACT OF MASS DRUG ADMINISTRATION AND INDOOR RESIDUAL SPRAYING ON MALARIA BURDEN IN A HIGH TRANSMISSION SETTING: A QUASI-EXPERIMENTAL STUDY DESIGN

Ronald Mulebeke[1], Humphrey Wanzira[1], Adoke Yeka[1], Jean-Pierre Van Geertruyden[2]

[1]Makerere University, KAMPALA, Uganda, [2]University Antwerp, Antwerp, Belgium

Mass drug administration (MDA) is likely to accelerate vector control impact. Yet exists little evidence on its impact on the malaria burden. We test the hypothesis that MDA plus indoor residual spraying (IRS) accelerates malaria burden reduction as compared to IRS.The study used a quasi-experimental design in three sub-counties of high malaria transmission endemicity where all received the standard of care. Toroma and Kapujan sub-counties received four rounds of IRS using primiphos-methyl (Acttellic SC300) six to eight months apart from December 2016 till December 2018. Kapujan sub-county received simultaneously with IRS, MDA using dihydroartemisinin-piperaquine (DHA-PQ). Patient data were collected routinely from health facilities and aggregated in the health management information system (HMIS), at the facility level, and into the District Health Information Software (DHIS2). Data were analyzed using interrupted time series (ITS) and difference-in-difference (DID) to estimate the differences in changes in malaria case incidence rate and test positivity rate and the value of MDA on IRS. Safety was recorded through passive surveillance and patients managed following the standard of care. This study was registered with the Pan African Clinical Trial Registry under PACTR 201807166695568. Malaria cases dropped by 83% (IRR: 0·17 (0·16- 0·18); p=0·001) while in the IRS arm, these drops were 47% (IRR: 0·53 (0·51, 0·56); p=0·001) in children under 5 years. A total of 6·85 (CI 95: 2·53, 11·19) cases per 1000 persons per month were prevented in the IRS+MDA arm compared to the IRS arm in under 5 years. TPR dropped at a rate of 21 positives per 1000 persons (p=0·003) and a month-to-month decline of 0·09 positives per 1000 persons (p=0·90) in children under 5 years. An additional decrease of 60 (p-value, 0·040) mean malaria cases among children under five years and a mean decrease in TPR of 16·16 (p-value, 0·001) was observed. MDA reduces malaria burden among children under 5 years suggesting it's a potential key strategy for malaria control and elimination in high transmission settings.

5402

ASSESSMENT ON THE RATIONAL USE OF ANTIMALARIA DRUGS IN HEALTH FACILITIES OF ETHIOPIA, CROSS SECTIONAL STUDY

Lydia Yohannes Ferenje, Natnael Solomon Hassan

Ministry of Health, Addis Ababa, Ethiopia

Malaria is one of the major causes of morbidity and mortality in in Ethiopia. Appropriate use of antimalarial drugs is vital in the effective management of malaria. This study helps to assess antimalarial drug use and level of adherence to national malaria treatment guideline and identify improvement areas at health facilities. To assess the rational use of anti-malarial drugs on the management of malaria cases in selected six health facilities in Ethiopia. Indicator based cross-sectional study was conducted by reviewing medical records of malaria patients who were treated from August 1, 2021, to June 30, 2022. Medical records of 540 patients were selected using systematic random sampling for data collection by standard questionnaire, exported to SPSS and descriptive analysis was done. 540 malaria patient medical records were reviewed. Most of the patients were male (55.7%), mean age of the patients was 22.9 years (SD=15.3) and 162 (30%) were children under 15 years. Only 136 (25%) of the patients were treated based on weight. Laboratory test was done for 463 (85.7%) of the patients, and 14.3% were treated without laboratory confirmation. Plasmodium falciparum species was the predominant species (54.9%), and most (39.1%) of the patients were diagnosed with severe malaria followed by uncomplicated malaria (23.3%). Primaquine co-administration was provided to only 124 (24.5%) of the patients, which is a small proportion compared to the need to provide it to all the patients. Parenteral IV of AR was shifted to PO within the recommended period for only 64.7% of the patients. Even though Primaquine is contraindicated during any trimester of pregnancy 3 pregnant women were given. In conclusion, there is low compliance to the national malaria treatment guideline and irrational use of antimalarial drugs. Prescription pattern of antimalarial drugs for most indicators was inappropriate. Health facilities should strengthen Drug Therapeutics Committees to continuously assess drug use at health facilities, design and implement interventions.

5403

ASYMPTOMATIC MALARIA AND ITS TREATMENT EFFECTIVENESS IN GIA LAI AND PHU YEN PROVINCES OF VIETNAM FOR THE MALARIA ELIMINATION ROADMAP GIA LAI AND PHU YEN PROVINCES OF VIETNAM FOR THE MALARIA ELIMINATION ROADMAP

Huynh Hong Quang[1], Nguyen Thi Minh Trinh[1], Nguyen Van Thanh[2], Chau Van Khanh[1], Pham Xuan Vinh[2], Ho Van Hoang[1], Le Van Dong[3], Michael D. Edstein[4], **Marina Chavchich**[4]

[1]Institute of Malariology, Parasitology, and Entomology, Quy Nhon, Viet Nam, [2]Military Institute of Preventive Medicine, Hanoi, Viet Nam, [3]Military Medical Department, Hanoi, Viet Nam, [4]Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia

A significant challenge for malaria elimination in Vietnam is the detection and elimination of asymptomatic malaria infections, which presents a hidden reservoir for malaria transmission contributing to the spread of drug-resistant malaria parasites. Gaining an understanding of the prevalence, distribution and persistence of asymptomatic malaria will help design intervention strategies to accelerate malaria elimination. Between 11 June 2022 and 17 February 2023, we screened 1,200 asymptomatic people (adults and children ≥ 5 years old) residing in Krong Pa district, Gia Lai province (n=1,045 people) and Song Hinh district, Phu Yen province (n=155) in Central Vietnam. Of these, 400 people (cohort 1) were living in close proximity to the previous year's symptomatic malaria cases and 800 people (cohort 2) were close contacts of the "index" symptomatic malaria cases associated with a concurrently run therapeutic efficacy study of pyronaridine-artesunate (Pyramax®). Finger prick blood samples were collected. All subjects were malaria negative by rapid diagnostic tests and blood film microscopy. RNA was extracted from 150 µL of blood and malaria parasites were detected by one-step RT-qPCR targeting 18S ribosomal RNA transcripts of Plasmodium falciparum, P. vivax, P. ovale and P. malariae. Of the 1,200 subjects, 77 (6.4%, CI 95%: 5.2-7.9%) were positive for malaria parasites by RT-qPCR, with 73 (94.8%) cases infected with P. falciparum and four cases of unknown speciation. The prevalence of asymptomatic malaria in cohort 1 of 1.8% (CI 95% 0.9%-3.6%) was significantly lower (P<0.0001), than that in cohort 2 amongst close contacts of the current symptomatic malaria cases of 8.8% (CI 95% 7.0%-10.9%). A total of 54 malaria positive subjects elected to be treated with Pyramax® (3-day course) and a single dose of primaquine. The study is ongoing with 25.9% (14/54) of treated subjects still being followed up to day 90 after starting treatment. The efficacy findings will be presented at the meeting. This information will inform the National Malaria Control and Elimination Program of Vietnam on strategies to accelerate malaria elimination in Vietnam.

5404

EVALUATION OF THE PERFORMANCE OF THE EXTENSION OF INVESTIGATIONS - RESPONSE OF MALARIA CASES IN THE REGION OF FATICK (SÉNÉGAL) FOR THE YEAR 2021

Elhadji Doucoure[1], Doudou Sene[1], Ibrahima Diallo[1], Alioune Badara Gueye[2], Yakou Dieye[3], Moustapha Cisse[3], Tidiane Thiam[3], Assane Ndiaye[4], Ibrahima Diouf[3]

[1]National malaria control program (NMCP), Dakar, Senegal, [2]PMI, Dakar, Senegal, [3]PATH/Macepa, Dakar, Senegal, [4]Medical Region, Ministry of Health and Social Action, Fatick, Senegal

In order to eliminate malaria in Senegal, investigations - responses to malaria cases started in 2013 initially in the northern zone of the country to interrupt local transmission. The Fatick Region is the first in the central zone to be enrolled in the extension phase in 2020 due to its low incidence. Evaluating the first year of activity is important to ensure proper implementation. The performance evaluation concerns the year 2021 and the entire Fatick region. The population of the eight districts is included. Data were obtained from registers, documentation forms, case listing, supervision reports, Tracker and DHIS2 platforms. Analyses were done with Excel software and the Tracker and DHIS2 analysis modules. 90% of the skilled workers and 20% of the community health workers were trained on the investigations. The completeness of the reports was 98% with 1333 malaria cases reported; 94% were documented within 24 hours and 94% investigated within 72 hours. The sex ratio was 3:1 in favor of females, and the age group 15 to 30 years represented 55% of the cases [1 month to 83 years]. There were 1299 uncomplicated cases, 34 severe cases and 1 death. The analysis of the travel history of the patients shows that a stay in the regions of Dakar and Diourbel was the most frequent, respectively 34% and 17%. The positive rate of RDTs during investigations with the FTAT approach was 0.38% (177 cases/45424 tests); there was a 0.1% refusal from the population and a need for 10733 LLINs in the concessions visited was identified. On the other hand, 55 cases of outbreaks were detected with 6557 people treated. The results of the first year of investigations show a successful implementation in the Fatick region. It is necessary to work for a change in the behavior of the 15-30 year old age group, which bears the main burden. The distribution of LLINs through investigations must be strengthened given the gaps observed. Also, the weakness of the trained community actors must be corrected for the appropriation of the populations and the sustainability of the approach.

5405

EXPOSURE TO A MULTI-CHANNEL MALARIA SBC PROGRAM AMONG GOLD MINERS IN GUYANA

Suruchi Sood[1], Gabrielle Hunter[1], Jennifer Orkis[1], Lyndsey Mitchum[1], sean Wilson[2], Joann Simpson[2]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Breakthrough ACTION Guyana, Georgetown, Guyana

Early diagnosis and prompt treatment is critical for malaria elimination. Guyana's Ministry of Health has implemented a program to increase access to testing and treatment in remote gold mining communities where malaria is endemic. The program interventions cut across the social ecological model, including distribution of insecticide-treated nets and training community members as volunteer malaria testers (VMT) who can administer rapid diagnostic tests, provide treatment for individuals with uncomplicated cases of malaria, and conduct ongoing monitoring. In partnership with the USAID-funded Breakthrough ACTION project, the VMT program is complemented by a National Malaria Social and Behavior Change (SBC) strategy and a multi-channel SBC intervention, Little Mosquito Big Problem (LMBP), that utilizes culturally relevant activities and messaging to increase miners' perceptions of malaria risk and self-efficacy to sleep under LLINs, test for malaria, and complete treatment. A robust mixed methods evaluation of this program examined pre-and post-intervention changes in malaria knowledge, attitudes, and practices among gold miners in the study areas. The evaluation included cross-sectional surveys with approximately 1,200 adult miners in 2019 and 2022. At post-test 77% of miners recalled at least one LMBP campaign component and a third of the miners knew about the VMT program. Multivariable logistic regression analysis controlling for miner's sociodemographic characteristics and mining context found that exposure was associated with higher knowledge, progressive attitudes towards malaria prevention and treatment, self-efficacy for malaria-related behaviors, positive self-image, and availability of social support. The results highlight gains made in Guyana to address malaria in remote areas. Care-seeking behaviors were reported by slightly more than half of all miners, and as such, there continues to be the need for multi-level programs for malaria elimination and expanded reach of the program.

5406

CONSIDERATIONS FOR MEDICATION SAFETY FOR MASS DRUG ADMINISTRATION FOR PLASMODIUM FALCIPARUM MALARIA ELIMINATION

Michelle A. Chang[1], Bernadette Fouche[2], Jonas Rigodon[3], Jean Frantz Lemoine[4], Marc-Aurele Telfort[4]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Quisqueya University, Port-au-Prince, Haiti, [3]US Centers for Disease Control and Prevention - Haiti, Port-au-Prince, Haiti, [4]Ministere de la Sante Publique et de la Population, Port-au-Prince, Haiti

The use of mass drug administration (MDA) for malaria can have a large impact - ranging from rapidly decreasing morbidity and mortality during malaria outbreaks to potentially contributing to malaria elimination with multiple rounds. These two scenarios may carry different risk-benefit outcomes because of their differing levels of malaria transmission, yet there are few published reports on the implementation of safety measures in MDA campaigns notably for malaria elimination. A medication delivered to a large population should be both operationally appropriate and safe to justify its use in MDA. The ideal medication for MDA would meet the following criteria: efficacious in clearing all stages of the parasite, long prophylactic effect against new infections, a single dose regimen per round, safe in pregnancy, safe in common chronic medical conditions, minimal risk of drug-drug and drug-food interactions, low potential for drug hypersensitivity reactions, and associated with only minimal reports of adverse drug reactions (ADRs). In addition, rigorous screening algorithms to assess an individual's eligibility to participate may be implemented during the MDA campaign to further minimize the risk of adverse events. In 2020, the National Malaria Control Program in Haiti administered sulfadoxine-pyrimethamine (SP) and a single low dose of primaquine (PQ) to 42,249 people. We implemented a medical eligibility screening algorithm that found self-reported rates (preliminary data) of kidney or liver failure (1.92%), SP allergy (0.28%), PQ allergy (0.39%), currently taking other medications that required additional review before administering SP or PQ (4.58%); and among women 15-49 years old, known or possible pregnancy (9.44%), currently breastfeeding (19.92%). Additional screening questions or testing were administered as needed. For ADR monitoring, passive pharmacovigilance was implemented that detected four cases of Stevens-Johnson syndrome. A review of MDA screening procedures identified no errors. An analysis of our campaign procedures and experience will provide lessons learned to increase the safety of MDA campaigns.

5407

ELUCIDATING INTERSEASON RESIDUAL PLASMODIUM INFECTION IN HUMANS AND WILD MOSQUITOES TO GUIDE THE SUCCESSFUL IMPLEMENTATION OF INTERVENTIONS FOR MALARIA ELIMINATION

Inès G. Pare[1], Frédéric Guigma[1], Bernard M. Somé[1], Nicaise Djègbè[1], Thomas S. Churcher[2], Anna Cohuet Cohuet[3], Roch K. Dabiré[1], Dari F. Da[1]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]MRC Centre for Global Infectious Disease Analysis, Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [3]Maladies infectieuses et vecteurs : écologie, génétique, évolution et contrôle (MIVEGEC), Montpellier, France

In the efforts of malaria control, multiple interactive strategies need to be deployed in the field. Because of specific mechanisms and action of each strategy, it is critically important to assess the main epidemiological parameters of malaria transmission in natural setting. The responsibility of human and vector as the main Plasmodium reservoirs in the parasite transition between two malaria seasons is unclear. Here, we aim to investigate the seasonal variations of Plasmodium infection during the dry season emphasizing on the potential role of human and vector in Burkina Faso. A longitudinal survey was performed during an entire dry season of 6 months for P. falciparum infection combining molecular and microscopy analysis in school age-group of children who were classified into 4 cohorts. The first group consisted of confirmed-uninfected individuals, the second, malaria submicroscopic infections, the third, asymptomatic infected-children with low P.f densities (to monitor parasitemia progress), and the fourth group included malaria asymptomatic cases which were treated with antimalaria drug. In parallel, we examined the spatial and temporal distribution of the mosquito vectors and their Plasmodium infection status. Following approximately 1000 children revealed that humans remain the main parasite reservoir between malaria seasons: with more than 50% of P.f-asymptomatic carriers remain infected all dry season during which the vector was quasi-absent. Advanced molecular analysis using Plasmodium in blood samples will provide more information about the parasite genotypes. Interestingly, 95% of negative individuals for P. falciparum infection (naturally or by antimalarial treatment) remains uninfected until the start of the transmission season, implying that intervention such as mass drug administration in the absence of the vector could be more beneficial for malaria control.

5408

KNOWLEDGE AND PERCEPTIONS OF NATIONAL GUIDELINES FOR THE CASE MANAGEMENT OF MALARIA IN PREGNANCY AMONG HEALTHCARE PROVIDERS AND DRUG DISPENSERS IN THE CONTEXT OF MULTIPLE FIRST-LINE THERAPIES IN WESTERN KENYA: A MIXED METHODS STUDY

Caroline B. Osoro[1], Stephanie Dellicour[2], Eleanor Ochodo[1], Taryn Young[1], Feiko O. ter Kuile[2], Julie R. Gutman[3], Jenny Hill[2]

[1]Stellenbosch University, Cape Town, South Africa, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]United States Centers for Disease Control and Prevention, Atlanta, GA, United States

Emerging resistance to artemether-lumefantrine (AL) in Africa prompted the pilot introduction of multiple first-line therapies against malaria in the general population in western Kenya, potentially exposing women of childbearing age to antimalarials with unknown safety profiles in the first trimester. We undertook a mixed-methods study to explore the knowledge and perceptions of malaria treatment guidelines for pregnant women among healthcare providers and drug dispensers. Structured questionnaires were administered to 174 providers across 50 health facilities and 40 drug outlets. In-depth interviews (IDIs) were conducted with 33 purposively selected healthcare providers, drug dispensers, and health managers. Transcripts were coded by content analysis using the WHO health system building blocks framework. Descriptive analyses and Chi-square tests were used to report differences in proportions. There was a greater awareness of guidelines in health facilities (83/134 [62%]) versus drug outlets (16/40 [40%]) (p=0.023), and more staff in health facilities had been trained on malaria in pregnancy in the last year (49% vs 20%, p=0.002). Lack of training on malaria case management was also evident from the IDIs with drug outlet providers, who did not know the national malaria treatment guidelines and reported a lack of pregnancy tests. Knowledge of recommended antimalarials for treatment in the first trimester (72% vs 90%, p=0.02), second /third trimesters (70% vs 84%, p=0.07), and for severe malaria (50% vs 71%, p=0.02) was less common in drug outlets than health facilities. Providers reported using AL instead of quinine in the first trimester due to the side effects and unavailability. Patient preference was a major factor in the antimalarials prescribed. Health managers reported a lack of supervision of drug outlets due to insufficient funds. Almost all providers reported drug stock-outs, with quinine most affected. Improved training, regulation, and monitoring of drug outlet providers is warranted, in addition to regular supply of malaria commodities and pregnancy test kits to ensure adequate management of malaria in pregnancy.

5409

WHY DID BLACK SOLDIERS HISTORICALLY HAVE MORE PNEUMONIA THAN WHITE SOLDIERS IN THE US ARMY?

G Dennis Shanks

Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia

Black US Army soldiers had four times as much bacterial pneumonia as White US Army soldiers during both the US Civil War and World War 1 (WW1). Pneumonia case fatality rates were a third higher in Black soldiers during the US Civil War but were the same between the racial groups by WW1. During WW2 the use of antibiotics decreased bacterial pneumonia mortality rates 100-fold and apparently erased racial differences. Similar differences in bacterial pneumonia rates by racial group were observed in African colonial soldiers of the French and British Armies during WW1. Pneumonia rates in Indian, Pilipino and Puerto Rican soldiers suggested that genetic polymorphisms were not a decisive factor determining Black pneumonia mortality. Post-measles pneumonias did not suggest an immune deficit in Black soldiers. Geographic focus of pneumonia in Black soldiers from the southern USA States and other tropical regions raises the possibility that increased bacterial pneumonia rates were indirectly related to malaria infections. Malaria remains a difficult to measure but potentially important mortality risk factor in pneumonia.

ONE OUT OF TWO CHILDREN CARRIES MALARIA PARASITES: HIGH PREVALENCE OF ASYMPTOMATIC MALARIA AMONG CHILDREN IN THE AHANTA WEST DISTRICT, GHANA

Emmanuel Kobla Atsu Amewu[1], Amma Larbi[2], Rosemond Mawuenyega[2], Alexander Kwarteng[1]

[1]Kumasi Centre for Collaborative Research in Tropical Medicine, KNUST, Kumasi, Ghana, [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Malaria is a persistent problem in sub-Saharan Africa, particularly among children. The World Health Organisation (WHO) has set a goal to reduce cases by 50% and mortality by 90% by 2025. However, the asymptomatic carriage of parasites continues to pose a challenge. Rapid diagnostic tests (RDTs) are recommended for surveillance due to their ease of use and low technical requirements. In this study, we evaluate the performance of three RDTs for detecting Plasmodium falciparum and Pan Plasmodium in asymptomatic children in the Ahanta West Municipality of Ghana in December 2022. We collected demographic and medical information using a structured questionnaire and performed venepuncture to obtain peripheral blood for the malaria RDTs. The study included 113 participants with a mean age of 12.10±2.3; 70 (61.9%) were girls, and 25 (22.1%) reported receiving malaria treatment in the three months prior to data collection. Malaria positivity rates were 44.2% for Bioline, 49.6% for NxTek, and 52.2% for First Response, with an overall prevalence of 53.1%. No significant associations were found between asymptomatic malaria positivity and study variables. Our findings suggest a high prevalence of asymptomatic malaria even during the dry season, which may hinder current elimination strategies and contribute to the transmission of malaria. Additionally, individuals with asymptomatic malaria may act as reservoirs for malaria parasites, underscoring the need for continued surveillance and treatment.

5411

VIVAX MALARIA IN DUFFY NEGATIVE ETHIOPIAN PATIENTS SHOWS INVARIABLY LOW ASEXUAL PARASITAEMIA

Lemu Golassa[1], Andargie Abate[1], Isabelle Bouyssou[2], Solenne Mabilotte[3], Cecile Lang[3], Laurent Dembele[4], Didier Menard[5], Eugenia Lo[6]

The detection of Plasmodium vivax infection among Duffy negative individuals in Africa has challenged the established dogma of the associations between Duffy antigen and P.vivax invasion of reticulocytes. The human host P.vivax relationship has brought new insights in the impact of Duffy polymorphisms on the epidemiology of malaria. The objective of this study was to determine the prevalence of P.vivax among Duffy negative and Duffy positive individuals; and to compare parasite density in those patients. Identification of Plasmodium species was performed by microscopic examination on field sites and by real time PCR in the laboratory. Genotyping of Duffy antigens was followed by DNA sequencing to determine its polymorphisms in a total of 138 P.vivax infected samples. The proportion of Duffy negative among P. vivax infected patients was 2.9% (4/138) with FYB/FYBES and FYA/FYBES genotypes being the common variants. However, FYBES/FYX genotype was only seen in two P. vivax infected patients. Low P. vivax parasitemia was counted in individuals with FYBES/FYBESand FYBES/FYX genotypes. In conclusion, although P. vivax infects Duffy negative individuals, polymorphisms of Duffy antigens have effect on asexual parasitemia. Patients with Duffy negative had low density parasitaemia as compared to those with Duffy positives. Infection in Duffy negatives, remain undetected by the commonly used malaria diagnostic tools (microscopy and Rapid diagnostic tests) putting them as the silent reservoirs in fueling onward malaria transmission. This unquestionably affects the elimination efforts.

5412

EPIDEMIOLOGICAL STUDY TO ESTIMATE MALARIA PREVALENCE AND USE OF CONTROL MEASURES IN AN AREA WITH PERSISTENT TRANSMISSION IN SENEGAL

Fassiatou Tairou[1], Ibrahima Gaye[2], Saira Nawaz[3], Libasse Sarr[4], Birane Cissé[5], Babacar Faye[1], Roger C K Tine[1]

[1]Department of Medical Parasitology, Université Cheikh Anta Dlop of Dakar, Dakar, Senegal, [2]Institut en santé et développement (ISED), Université Cheikh Anta Dlop of Dakar, Dakar, Senegal, [3]Primary Health Care, PATH, Seattle, WA, United States, [4]Département de géographie, Université Cheikh Anta Dlop of Dakar, Dakar, Senegal, [5]Environnement et Santé, Département de Géographie, Université Cheikh Anta Dlop of Dakar, Dakar, Senegal

While there is evidence of malaria burden among under-five, limited data on malaria prevalence and use of control measures are available across all age groups in Senegal. As the country is shifting from control to elimination, there is a need to better understand malaria distribution across all age groups in order to guide future interventions. A cross-sectional survey was conducted in four health posts in the Saraya health district, an area with persistent malaria transmission during the 2021 transmission season. A multistage random sampling technique was used to select households and individuals over 6 months of age who consented were invited to participate. Socio-demographic data, household assets, and use of preventive measures were collected using an electronic questionnaire. Malaria parasites were screened by microscopic examination of blood smears, and hemoglobin levels were measured using a portable hemoglobinometer (Hemocue 301TM). Logistic regression was used to identify factors associated with malaria infection. Overall, 1759 participants were enrolled and P. falciparum prevalence was 20.5%. There is no statistically significant difference between the prevalence of under-five children (20.5%) and adolescents (26.6%), (p=0.52), nor between 5-10 years old children (26.6%) and adolescents (24.7%), (p=0.76). P falciparum accounted for 99.2% of the malaria infection, and 69% were asymptomatic. The odds of malaria was associated with the location of Khossanto (aOR=1.97, 95% CI: 1.35-2.88) and the primary education level (aOR=1.64, 95% CI: 1.08-

2.50). Around 33% of the study participants were anemic (hb<11g/dl), with under five children bearing the highest prevalence (67.3%). P. falciparum positive individuals (aOR=1.33, p=0.037), females (aOR=2.10, p=0.000), and under-five children (aOR=11.90, p=0.000) were more at risk of anemia. Bed net usage was lower among adolescents (31,1%) compared to 48.0% for under five and 41.2% for 5-9 years old children. Malaria prevalence was higher among adolescents. Interventions tailored to this specific population group are needed to better control the disease and reduce its burden.

5413

MALARIA TRENDS DURING THE COVID-19 PANDEMIC IN THE CITY PROVINCE OF KINSHASA / DR CONGO

Brigitte Laishe

Ministère de la santé publique, Kinshasa, Congo, Democratic Republic of the

Malaria Trends During The COVID-19 Pandemicin The City Province Of Kinshasa / Dr Congo. Laishe B1, Musema B2, Mukomena E1,3, Likwela J4 National Malaria Control Program, RD Congo 2. University of Kinshasa, 3 . University of Lubumbashi, 4 University of Kisangani, I.

Malaria is one of the scourges that concern the world with high morbidity and mortality In 2019, 212 million cases of malaria were recorded worldwide with 429,000 deaths. The African region is the most affected and accounts for 89% of all cases and 91% of deaths recorded worldwide (WHO 2019). In DR Congo, malaria is the leading cause of hospitalization among children under 5 and pregnant women. Added to this is the occurrence of the COVID-19 pandemic with the highest lethality (2.6%) (Epidemiological Bulletin 2020). We want to know if the COVID-19 pandemic has an impact on the proportions of malaria in the city of Kinshasa. II. We carried out a cross-sectional study using data from the annual reports of the PNLP / DR Congo edition 2019 and 2020. In 2019, about 2,249,789 suspected cases of malaria were registered, 1,270,497 confirmed cases (56%, 119,009 serious cases and 973 deaths. In 2020, 2,148,169 suspected cases, 1169,841 (54.5%) confirmed cases, death.The results of this study revealed no significant difference. The increase in deaths during the pandemic period is justified by the fact that at the start of this pandemic, the population had deserted the health structures. In conclusion, COVID-19 appears to have no impact on the proportions of malaria cases. Large-scale studies across the country need to be conducted to confirm these findings.

5414

FACTORS ASSOCIATED WITH ACTIVE PRIVATE HEALTH PROVIDER FOLLOW-UP OF PLASMODIUM VIVAX PATIENTS TREATED WITH PRIMAQUINE IN MYANMAR

May Me Thet[1], Myat Noe Thiri Khaing[1], Su Theingi Aung[1], Sandar Oo[1], Moe Myint Oo[1], Lee-Ann Gallarano[2]

[1]Population Services International Myanmar, Yangon, Myanmar, [2]Population Services International, WASHINGTON DC, BC, United States

Recorded cases of Plasmodium vivax have risen in Myanmar since 2019, with 39342 cases reported in 2022, almost double that of 2021. Myanmar aims to eliminate P. vivax by 2030. Elimination will require patient adherence to radical cure with primaquine (PQ), which has hitherto proven difficult due to the 14-day dosing regimen. Adherence can be supported by active provider follow-up. We developed a suite of tools to support malaria care providers, including an NMCP-approved direct observation treatment form, patient counseling form and case management guide. A cross sectional mixed-method study was conducted with private general practitioners (GPs) and trained informal private outlet (PO) providers to investigate knowledge, attitudes, and practices related to P. vivax treatment and explore opinions of the new tools. A total of 216 GP and 204 PO providers completed a quantitative survey, which was followed by qualitative in-depth interviews (IDIs) with 10 GP and 6 PO. Descriptive and logistic regression analyses were conducted for survey data and deductive content analysis performed on qualitative data. Providers had excellent knowledge of P. vivax treatment, with 99.1% of GPs and 94.1% of POs correctly citing the national guidelines. However, only 25.5% of GP and 79.4% of PO reported that they usually followed-up patients who were treated with PQ. Multivariate regression identified the following significant determinants of patient follow-up: providers aged above 60 yrs (aOR=0.39, p=0.016), provider education above high school (aOR=0.15, p<0.001) and providers in rural areas (aOR=1.9, p=0.019). IDIs revealed transportation and connectivity at patients' location and poor patient awareness of the importance of adherence as challenges to patient follow-up. Providers valued the new tools and believed that they would help improve treatment adherence and monitoring PQ side effects. However, providers could not complete the counseling form for every patient when their case load was high. The study highlighted additional customized program support is needed to support providers with active patient follow up per treatment guidelines.

5415

DISTRIBUTION OF ANOPHELINES AND MALARIA PREVALENCE ACCORDING TO HOUSE STRUCTURE AND COMMUNITY PRACTICES DURING A LARVICIDING PROGRAM IN THE CITY OF YAOUNDÉ, CAMEROON

Carmène Sandra Ngadjeu[1], Abdou Talipouo[1], Patricia Doumbe-Belisse[1], Parfait Awono-Ambene[2], Sevilor Kekeunou[3], Charles Sinclair Wondji[4], Christophe Antonio-Nkondjio:[2]

[1]OCEAC/University of Yaounde I, Yaoundé, Cameroon, [2]OCEAC, Yaoundé, Cameroon, [3]University of Yaounde I, Yaoundé, Cameroon, [4]Vector Group Liverpool School of Tropical medicine Pembroke Place, Liverpool L3 5QA, UK, liverpool, United Kingdom

The most efficient malaria vectors bite and rest inside houses, hence houses play a determinant role in malaria transmission. During the implementation of additional vector control tools such as larviciding, individual disease risk perception could be affected. We carried out this study to evaluate the influence of house structures, community knowledge and practices on anophelines diversity and malaria prevalence, before and during a larviciding program. The study was conducted before and during larviciding intervention in 26 districts. Indoor CDC light traps were used to collect mosquitoes. Questionnaires were administered to collect data on house characteristics and to assess the impact of larviciding on population knowledge and behaviour. After morphological identification, anophelines were tested by ELISA to detect infection to Plasmodium parasites. RDT was used to test the blood samples of participants. Binary analyses were used to assess the correlation between different variables. The majority of houses were made with cement walls. The most abundant anophelines was Anopheles coluzzii, followed by An. gambiae s.s, with the highest densities in traditional houses before the treatment and in control sites, whereas, they were most abundant in modern houses in treated sites. Opened eaves and the absence of a ceiling exposed people to anopheline bites. Possession of LLINs before the treatment and in control sites exposed people to anopheline bites while they were protected in treated sites. Infection to Plasmodium and malaria prevalence were highest in modern houses found in control sites; while in treated sites, infection to Plasmodium was high in modern houses, but malaria prevalence was the same in both house types. People who lived in treated sites knew more about malaria prevalence and mosquito breeding sites, and the latter used fewer LLINs. Well-built houses protect people against anophelines species. The implementation of larvicide control improved the knowledge of people and decrease their personal protection against mosquito bites.

5416

BREAKING THE MALARIA CYCLE; ASSESSMENT OF REPEAT MALARIA INFECTIONS IN LAKE ENDEMIC REGION OF WESTERN KENYA, JUNE 2021-MAY 2022

Jedidah W. Kiprop[1], Geoffrey K. Githinji[1], Fredrick O. Odhiambo[1], Maurice O. Owiny[1], Elvis Oyugi[2]

[1]Field Epidemiology and Laboratory Training Program, Ministry of Health, Nairobi, Kenya, [2]Division of National Malaria Program, Ministry of Health, Nairobi, Kenya

The burden of malaria in Kenya is not uniformly distributed, with the Lake-endemic region in Western Kenya having a prevalence of 19% compared to the national average of 6%. There's limited data on repeat malaria infections in this region. We sought to characterize repeat malaria infections epidemiologically and identify associated factors among outpatients.We reviewed medical records from 1st June 2021 through 31st May 2022 in nine public health facilities in three counties in the Lake-endemic region. The study population was patients diagnosed with confirmed malaria. Temporal, demographic and diagnostic data were abstracted using a standardized template from outpatient and laboratory registers. A repeat malaria infection was defined as confirmed parasitemia in a patient fourteen days after treatment initiation. The outcome variable was >1 confirmed malaria episode in the same patient. Analysis was performed using Epi Info v7.2.5. We calculated means and medians for continuous variables, frequencies and proportions for categorical variables. Chi-square test was used to measure the association between repeat infections and independent variables and factors with p<0.05 were considered statistically significant. We analyzed 26,133 records; 12% (3,132/26,133) were repeat malaria cases, 64% (1,993/3,132) were aged <15 years and 27% (844/3,132) < 5 years. The majority, 87% (2,728/3,132), had one repeat infection, and 15.2% (476/3,132) had more than one episode. The median duration to repeat episodes was 146 days (IQR:51-341). Overall, diagnosis by microscopy was 57% (1,783/3,132) and 43% (1,335/3,132) by RDT. Healthcare workers adhered to national treatment guidelines in 88.2% (1,683/1,909) cases representing 90.6% (727/802) among <5 years and 86.4% (956/1,107) among 5-14 years. We found an association between diagnosis and patients <5 years (cOR 1.5, 95%CI 1.1-2.1).Persons aged <15 years had the highest burden of repeat infections. The malaria lake-endemic counties should enhance laboratory surveillance and treatment for repeat malaria infections in children.

5417

INSIGHTS INTO THE IMPLEMENTATION OF A LIFE-SAVING INTERVENTION: A PROCESS EVALUATION OF PRE-REFERRAL RECTAL ARTESUNATE SUPPOSITORIES ADMINISTRATION IN CHILDREN FROM RURAL ZAMBIA FOR SEVERE MALARIA

Andrew Andrada[1], Ernest Chanda[2], Irene Kyomuhangi[1], Jayne Webster[3], Stephen Bwalya[2], Busiku Hamainza[2], Arantxa Roca-Feltrer[4], Adam Bennett[4], Mulakwa Kamuliwo[2], Ruth Ashton[1], Refilwe Karabo[1], Zhiyuan Mao[1], John M. Miller[5], Thomas P. Eisele[1], Kafula Silumbe[5]

[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]National Malaria Elimination Centre, Lusaka, Zambia, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]PATH, Seattle, WA, United States, [5]PATH MACEPA, Lusaka, Zambia

Children with severe malaria in remote rural areas have the highest risk of malaria mortality. Appropriate malaria treatment may be delayed due to travel costs, geographical barriers, and travel distances. Rectal artesunate suppositories (RAS) administered by community health workers as a pre-referral treatment for severe malaria (SM) have been shown to help save the lives of children with SM by greatly reducing their parasite load. These children must still be taken to referral hospitals for case management and completion of antimalarial treatment, or risk parasite resurgence. Recent observational studies found that children with SM in regions where RAS was being implemented had an increased risk of dying compared to regions without RAS. This surprising result led to the WHO revising its recommendations on RAS implementation and encouraged process evaluation of ongoing in-country implementations. The National Malaria Elimination Centre (NMEC) of Zambia along with its partners, successfully piloted the RAS intervention package in 2017 and has since scaled it up to 10 districts in Zambia. This mixed-methods study assesses real-world implementation of the RAS intervention package across three districts in Zambia with varying implementation experience. The primary objectives are to ascertain service availability and readiness of service providers across the cascade of care for severe malaria, enumerate what proportion of severe malaria cases complete each step along the cascade, describe where children with severe malaria are dying and why, and identify perceptions, facilitators, and barriers to referral care for caregivers and other community members. Data collection is being conducted during peak malaria transmission season and preliminary results will be presented. These results will provide critical information for the NMEC and its partners. In addition, it will provide a more holistic understanding of the RAS intervention package, which may help improve RAS implementation in other countries and reduce mortality among children in remote rural areas with severe malaria.

5418

HELMINTH AND MALARIA CO-INFECTION AMONG PREGNANT WOMEN IN TWO DISTRICTS OF THE VOLTA REGION OF GHANA

Sarah Alhakimi[1], Navneet Kaur[1], Javeriya Choudry[1], William K. Anyan[2], Abraham K. Anang[2], **Nilanjan Lodh**[1]

[1]Marquette University, Milwaukee, WI, United States, [2]University of Ghana, Accra, Ghana

In sub-Saharan Africa, approximately 40 million pregnant women are exposed to parasitic diseases such as malaria caused by Plasmodium falciparum, Schistosome parasites, and soil-transmitted helminth (STH). When parasitic diseases share the same habitat and overlap in distribution then high rates of co-infection occur. The co-infection can lead to consequences for the child, such as intrauterine growth retardation, low birth weight, pre-term delivery, and neonatal mortality. The objective of the study was to determine the nature and extent of coinfection from 100 samples collected from the Battor (50) and Adidome (50) districts of Ghana in collaboration with Noguchi Memorial Institute for Medical Research, University of Ghana. Out of 50 for the Adidome district determined for P. falciparum by RDT, Malaria PAN, and Malaria Pf kit, 39 were true positive (TP), 8 were true negative (TN), and 30 were false negative (FN). For Battor, 19 were TP, 12 TN, and 20 FN. For S. mansoni in Adidome via polymerase chain reaction (PCR) and loop-mediated isothermal amplification (LAMP), 21 tested positive, and 29 negatives with 52.5% sensitivity and 100% specificity. For S. haematobium, 28 were positive and 22 negatives using PCR with 70% sensitivity and 100% specificity. In LAMP, 28 were positive, and 22 negatives with 70% sensitivity and 100% specificity. In Battor PCR for S. mansoni, 28 positives and 22 negatives with 68.3% sensitivity and 100% specificity. In LAMP, 32 were positive, and 18 were negative with 80% sensitivity and 100% specificity. For S. haematobium, PCR showed 30 positive and 20 negative with 73.2% sensitivity and 100% specificity. With LAMP, 21 were positive, and 29 negatives with 51% sensitivity and 100% specificity. In both district age groups, B (20-30 years) had the highest infection prevalence for P. falciparum, S. mansoni, S. haematobium, and Strongyloides stercoralis. The results will be utilized as a part of the continuous surveillance for future research aiming at gathering nationally representative data in Ghana on the prevalence of coinfection and proposing interventions based on that for the vulnerable pregnant women population.

5419

TARGETING MALARIA CONTROL EFFORTS IN MALAWI: OUTPUTS AND RECOMMENDATIONS FROM A WORKSHOP ON BURDEN STRATIFICATION FOR THE 2023-2030 STRATEGIC PLAN

Donnie Mategula[1], Colins Mitambo[2], William Sheahan[3], Nyanyiwe Masingi Mbeye[4], Austin Gumbo[5], Colins Kwizombe[6], Jacob Kawonga[7], Benard Banda[7], Gracious Hamuza[5], Alinafe Kalanga[8], Dina Kamowa[9], Jacob Kafulafula[10], Akuzike Banda[5], Halima Twabi[11], Esloyn Musa[9], Atupele Kapito-Tembo[12], Tapiwa Ntwere[9], James Chirombo[1], Patrick Ken Kalonde[1], Maclear Masambuka[13], Lumbani Munthali[5], Melody Sakala[1], Abdoulaye Bangoura[14], Judy Gichuki[15], Michael Give Chipeta[16], Beatriz Galatas Adrade[17], Michael Kayange[18], Dianne J. Terlouw[1]

[1]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [2]Research Unit, Ministry of Health, Lilongwe, Malawi, [3]PATH, Seatle, WA, United States, [4]School of Global and Public Health, Kamuzu University of Health Sciences,, Blantyre, Malawi, [5]National Malaria Control Programme, Ministry of Health, Lilongwe, Malawi, [6]U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Lilongwe, Malawi, [7]Country Health Information Systems and Data Use (CHISU) Program, Lilongwe, Malawi, [8]MulanjeDistrict Council, Mulanje, Malawi, [9]Kamuzu University of Health Sciences, Blantyre, Malawi, [10]Nkhotakota District Council, Nkhotakota, Malawi, [11]Department of Mathematical Sciences, School of Natural and Applied Sciences,University of Malawi, Zomba, Malawi, [12]School of Public Health,Kamuzu University of Health Sciences, Blantyre, Malawi, [13]Kasungu District Council, Kasungu, Malawi, [14]PMI VectorLink Project, Abt Associates,, Lilongwe, Malawi, [15]Strathmore University, Institute of Healthcare Management, Nairobi, Kenya, [16]African Institute for Development Policy (AFIDEP), Lilongwe, Malawi, [17]World Health Organization, Geneva, Malawi, [18]World Health Organization, Lilongwe, Malawi

Malawi's National Malaria Control Programme (NMCP) is developing a new strategic plan for 2023-2030 to combat malaria and recognizes that a blanket approach to malaria interventions is no longer feasible. To inform this new strategy, the NMCP set up a task force comprising 18 members from various sectors, which convened a meeting to stratify the malaria burden in Malawi and recommend interventions for each stratum. The burden stratification workshop took place from November 29 to December 2, 2022, in Blantyre, Malawi, and collated essential data on malaria burden indicators, such as incidence, prevalence, and mortality. Workshop participants reviewed the malaria burden and intervention coverage data to describe the current status and identified the districts as a appropriate administrative level for stratification and action. Two scenarios were developed for the stratification, based on composites of three variables. Scenario 1 included incidence, prevalence, and under-five all-cause mortality, while Scenario 2 included total malaria cases, prevalence, and all-cause mortality counts in children under five. The task force developed four burden strata (highest, high, moderate, and low) for each scenario, resulting in a final list of districts assigned to each stratum. The task force concluded with 10 districts in the highest-burden stratum (Nkhotakota, Salima, Mchinji, Dowa, Ntchisi, Mwanza, Likoma, Lilongwe, Kasungu and Mangochi) 11 districts in the high burden stratum (Chitipa, Rumphi, Nkhata Bay, Dedza, Ntcheu, Neno, Thyolo, Nsanje, Zomba, Mzimba and Mulanje) and seven districts in the moderate burden stratum (Karonga, Chikwawa, Balaka, Machinga, Phalombe, Blantyre, and Chiradzulu). There were no districts in the low-burden stratum. The next steps for the NMCP are to review context-specific issues driving malaria transmission and recommend interventions for each stratum. Overall, this burden stratification workshop provides a critical foundation for developing a successful malaria strategic plan for Malawi.

5420

COMMUNITY HEALTH VOLUNTEER CONTRIBUTION TO MALARIA SURVEILLANCE IN SIAYA COUNTY, WESTERN KENYA

Wycliffe Odongo[1], Kizito Obiet[2], Brian Seda[2], Victoria Seffren[1], Oliver Towett[2], Simon Kariuki[2], Feiko ter Kuile[3], Titus Kwambai[1], Gutman Julie[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Significant efforts have been undertaken to improve malaria surveillance data in Africa. These efforts are geared towards transforming surveillance into a core intervention. Despite these, there has been little emphasis on granular analysis of community case management of malaria (CCM) data. We reviewed 3 scannable registers routinely completed by community health volunteers (CHV) in Siaya County, western Kenya: household and service delivery registers and daily activity log. We analyzed line-listed data from 416 CHVs covering 443 villages in 73 community units (CU) in 2021-2022. The household registration in 2022 documented 250,707 people (128,926 Rarieda, 118,372 Alego Usonga). Over the year, 47% were offered CCM services by CHVs. Vitamin A, family planning, and routine check-ups were the most frequent referrals constituting 19% (n=16,454) of total referrals by CHVs to health facilities. In 2022, CCM evaluations rose from 12,513 to 21,044; CHVs performed 17% of total tests and identified 20% of all malaria cases in both sub-counties. Mean monthly rapid diagnostic tests (RDTs) performed per CHV increased from 2.1 to 5.2 in the same period. During this period, 33,197 RDT tests were done by CHVs, 75.0% (n=24,729) among febrile patients. 83.5%(n=20661) of febrile and 79.6% (n=6715) of afebrile cases tested positive for malaria. 95% (n=26015) of RDT positive cases were treated with artemisinin combination therapy, spotlighting. Overall, test positivity rate (TPR) was high: 82.5%, with mean CU TPR of 87.3% (95% CI:85.2-89.4) in Alego Usonga and 82.4% (95% CI:80.8-83.9) in Rarieda. Interestingly, village level TPR was over 80% in 247 villages, substantially higher than health facility TPRs: 56.4% overall, 64.9% (95% CI;63.3-66.7) Alego Usonga, 54.6% (95% CI;51.5-57.7) Rarieda. The discrepancy between CU and facility TPR suggests a community bias towards CHV care for people who think they have malaria while those suspecting another illness go to the facility. Further investigation is needed to better understand care-seeking behaviors and whether these TPR differences are real.

5421

MALARIA TEST POSITIVITY RATES IN COMMUNITY SURVEILLANCE AS COMPARED TO HEALTH FACILITY SURVEILLANCE IN MALARIA ENDEMIC AREA RARIEDA SUB-COUNTY, WESTERN KENYA

Brian Louis O. Seda[1], Wycliffe Odongo[2], Oliver Towett[1], Kizito Obiet[1], Victoria Seffren[3], Aaron M Samuels[3], Simon Kariuki[1], Feiko O ter Kuile[4], Julie R. Gutman[3], Titus K Kwambai[3]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta GA, USA, Atlanta GA,USA, GA, United States, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta GA, USA, Atlanta GA, GA, United States, [4]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, UK, Liverpool, United Kingdom

In malaria endemic western Kenya, community case management (CCM) for malaria is a key strategy to increase access to care and provide prompt diagnosis and treatment. However, there are few data assessing the proportion of malaria cases identified by community health volunteers (CHV) compared to facility out-patient departments (OPD) in our setting. In Kenya, CHVs are organized in community units (CUs), which consists of a number of villages and the health facilities that they are linked to. CHVs visit households with reported malaria symptoms, and test and treat them

for malaria and other health conditions. These data are recorded in CHV Activity Registers (CHV-AR) which was digitized using ocular character recognition technology (ScanForm) to enhance quality, timeliness, and data use of information collected in this register.We analyzed data collected between January 2021–December 2022 from 35 health facility OPD ScanForm registers (stratified by age to <5yrs, 5–14yrs and 15+yrs) and CHV-ARs from the corresponding 39 CUs covering 397 villages with a total population of about 128,926 people in Rarieda sub-county, western Kenya. We reviewed the number of persons tested for malaria and calculated test positivity rates (TPR). Overall, 229,511 malaria tests were performed, including 203,208 at OPD (5yrs=40,326, 5–14yrs=63,321, 15+yrs=99,435) and 26,598 in the community (<5yrs=7,770, 5–14yrs= 9,453, and 15+yrs=9,080)The overall TPR was 56.4% at OPD (<5yrs=51.9%, 5–14yrs=69.3%, 15+yrs=48.1%) and 81.1% in the community (<5yrs=85.3%, 5–14yrs=82.5%, 15+yrs=76.0%). Community cases accounted for 11.5% of all malaria tests but 16.1% of all positive cases, highlighting the high TPR in the community. Appropriate provision of artemisinin-based combination therapy for test positive cases was 92.4% at OPD and 95.1% at the community. Despite significant utilization of health facilities, the burden of symptomatic malaria in the community remains high. Our data suggest that CHVs appropriately follow testing and treatment guidelines and reach a population in need. Further support for the CCM should be considered to increase the reach of CHVs.

5422

IMPLEMENTING HIGH QUALITY COMMUNITY CASE MANAGEMENT AND DATA REPORTING: LESSONS FROM THE FIELD IN SIAYA, WESTERN KENYA

Kizito O. Obiet[1], Wycliffe Odongo[2], Brian Seda[3], Victoria Seffren[2], Oliver Towett[3], Simon Kariuki[3], Feiko O. ter Kuile[4], Titus K. Kwambai[5], Julie Gutman[2]

[1]Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]US Center for Disease Control and Prevention, Atlanta, GA, United States, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]US Center for Disease Control and Prevention, Kisumu, Kenya

Malaria is still a major cause of mortality and morbidity in western Kenya, despite implementation of recommended malaria control interventions. Community case management of malaria (CCM), implemented by Community Health Volunteers (CHVs), is a key strategy for timely identification of fever cases and management. However, inadequate data capture tools, training and supervision affect the quality of data. We aimed to track access to diagnostics, treatment, and referral services offered by CHVs using scannable registers to enhance accurate data capture and reporting. In 2021, we deployed scannable registers in 2 sub-counties, in Siaya County, western Kenya. 914 CHVs covering 975 villages in 89 community units (CU) attached to 95 health facilities were trained on the use of scannable registers and senior MoH staff trained on supervision and data quality review, including summary dashboards.34 CUs up from 22 CUs in Alego Usonga began reporting during the implementation period (out of 50). In Rarieda, which has received support since 2021, all CUs are reporting (n= 39). There was an increase in the number of malaria positive cases reported by CHVs, from 8653 in 2021 to 12955 in 2022. While cases seen at the health facility decreased (from 61370 to 51842), the proportion of overall cases seen by a CHV increased from 12.4% in 2021 to 20%. More frequent (Monthly) data reviews at CU level as opposed to quarterly at sub-county level improved reporting timeliness. We uncovered gaps in data collection, review, tallying and reporting. Delayed reports prevented action on critical interventions e.g., restocking malaria testing and treatment commodities. Multiple registers collecting similar indicators presented challenges for CHVs. Therefore, streamlining existing data tools and ensuring partner coordination could reduce CHV workload and improve efficiency. Routine data reviews provide opportunities for supportive supervision and could improve quality of care and data. Integrating and automating tallies from CHV line-listed data into DHIS2 could enhance data quality and facilitate analyses for more targeted malaria control interventions.

5423

NON-RANDOM DISTRIBUTION OF PLASMODIUM SPECIES INFECTIONS AND ASSOCIATED CLINICAL OUTCOMES IN CHILDREN 3-17 YEARS OF AGE IN THE LAKE VICTORIA REGION, KENYA, 2012-2020

Protus Okwato Omondi[1], Brian Musyoka[1], Takatsugu Okai[1], James Kongere[1], Wataru Kagaya[1], Chim W. Chan[1], Achyut K. C[2], Jesse Gitaka[3], Akira Kaneko[2]

[1]Department of Parasitology, Graduate school of Medicine Osaka Metropolitan University, Osaka City, Japan, [2]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden, [3]Directorate of Research and Innovation, Mount Kenya University, Nairobi, Kenya

Plasmodium falciparum (Pf), P. malariae (Pm), and P. ovale (Po) infections are endemic in Kenya. However, plasmodium species mixed infections (co-infections) have not been well documented. We assessed the distribution of co-infections and associated clinical features in the Lake Victoria region of Kenya. Twelve school-based cross-sectional surveys were conducted in Mfangano island and Ungoye village between 2012-2020. Peripheral blood was collected on filter paper for dried blood spots from children aged 3 to 17 years. Plasmodium infection was determined by microscopy and nested polymerase chain reaction (nPCR). The multiple-kind lottery (MKL) model calculated the expected distribution of plasmodium infections in the population and compared it to observed values using a chi-squared test ($\chi 2$); a p-value of 0.05 was considered statistically significant. Multivariate logistic regression model generated adjusted odds ratios (aOR) adjusting for age, sex, school, and survey year and 95% confidence intervals (CI) to assess any association between co-infections, and fever (axillary temperature above 37.5°C), splenomegaly (clinically palpable spleen), and anemia (hemoglobin below 11 g/dl) all measured on the day of the survey. The plasmodium prevalence by nPCR was 41.3% (6849/16563). Among all infections (6849), Pf, Pm, and Po mono-infections were 60.1%, 4.1%, and 2.4%, respectively. Pf-Pm, Pf-Po, Pm-Po, and Pf-Pm-Po co-infections were 21.5%, 3.4%, 0.2%, and 6.9%, respectively. MKL modeling revealed non-random distributions with frequencies of Pf-Pm and Pf-Pm-Po co-infections higher than expected ($\chi 2$=2130, p<0.001). Pf co-infections with Pm and or Po were associated with a decreased risk of fever (aOR 0.70, 95% CI 0.56-0.87; p=0.03). Co-infections with Pf were associated with splenomegaly (aOR 2.79, 95% CI 2.13-3.64; p<0.001) and anemia (AOR 1.23, 95% CI 1.00-1.50; p=0.04) compared to single-species infections. Plasmodium co-infections were common and non-randomly distributed. Prompt diagnosis and adequate treatment of plasmodium co-infections are urgently needed for malaria elimination to be realized in Kenya.

5424

DYMANICS OF SUBMICROSCOPIC MALARIA INFECTION IN SOUTHERN BENIN

Akpeyedje Yannelle Dossou

Institut de Recherche Clinique du BENIN, Abomey-Calavi, Benin

Since 2016, malaria cases have increased; the largest annual increase of 13 million cases was observed between 2019 and 2020 during the first year of the COVID-19 pandemic according to WHO. In Benin, malaria transmission occurs throughout the year with a peak during the rainy season. Since 2000, there has been a progressive increase in the number of new cases of malaria in Benin, despite the various control strategies in place. According to Health Statistical Yearbook 2021, malaria is the first cause (44.6%) of outpatient consultations in public health facilities. Malaria remains a major public health problem in Benin, which is struggling to control morbidity and mortality. Benin, has set a target of malaria elimination.This study was conducted in urban areas of Adjrako in south of Benin, located in the Atlantic department in the south of Benin; All 1064 inhabitants of Adjrako village were screened for malaria in 2021. Then the following year, 436 individuals from the same village were also screened. Factors influencing submicroscopy and microscopy were studied, using an ordered polytomous logistic regression model.Of the total number of infections,

86.49% were asymptomatic in the dry season and 82.95% in the rainy season. The proportion of individuals with asymptomatic infections was 34.30% and 49.88% in the dry and rainy seasons respectively. Whether in the dry or rainy season, individuals between 5 and 15 years of age have the largest infectious reservoir (50.8% in the dry season and 70.1% in the rainy season) followed by those over 15 years of age (41.1% in the dry season and 60.3% in the rainy season) and then by those under 5 years of age (21.6% and 42.5%) In univariate polytomous logistic regressions, the effect size for age was high in both years and significant ($p < 0.001$). During the rainy season, the risk was greater for 5-15 year olds (OR: 3.43 [95% CI: 2.44- 4.81]) than for those over 15 years old (OR: 2.00 [95% CI: 1.42 - 2.81].Our results confirm the ubiquity of the asymptomatic reservoir in the dry and rainy seasons. Age, sex, season and the use of preventive measures played a role in explaining the asymptomatic infections..

5425

HIGH PROPORTION OF LOW PARASITAEMIA AND SUBMICROSCOPIC MALARIA INFECTIONS IN HONDURAN MOSKITIA

Gabriela Matamoros[1], Denis Escobar[1], Alejandra Pinto[1], Delmy Serrano[2], Eliška Ksandrová[1], Nicole Grimaldi[1], Gabriel Juárez-Fontecha[1], Marcela Moncada[1], Danielle Pannebaker[3], **Hugo Valdivia**[3], Gustavo Fontecha[1]

[1]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, [2]Hospital de Puerto Lempira, Puerto Lempira, Honduras, [3]U.S. Naval Medical Research Unit No. 6, Lima, Peru

Efforts towards malaria elimination in Honduras have achieved substantial progress and reductions in the incidence of cases in the country. La Moskitia, a region with the highest concentration of malaria infections in the country, reported less than 800 cases in 2020. However, achieving and sustaining malaria elimination requires the implementation of highly sensitive tests that can detect low-density parasitemia to identify asymptomatic and submicroscopic carriers. In this study, we implemented photoinduced electron transfer polymerase chain reaction (PET-PCR) and assessed its performance versus light microscopy and conventional nested PCR (nPCR) on 309 whole blood samples collected from febrile subjects using a passive surveillance approach at the Puerto Lempira hospital in Gracias a Dios, Honduras. Different diagnostic performance metrics were calculated including sensitivity, specificity, negative and positive predictive values, kappa index, accuracy, and ROC. Malaria prevalence was estimated at 19.1% by Light Microscopy (LM), 27.8% by nPCR, and 31.1% by PET-PCR with 40 and 13 cases missed by LM and nPCR, respectively. The sensitivity of LM and nPCR was 59.6% and 80.8% using PET-PCR as the reference test. LM showed a kappa index of 0.67, with a moderate level of agreement. This study identified a prevalence of 12% submicroscopic malaria among febrile cases in the Honduran Moskitia. Potential asymptomatic malaria cases are not routinely tested, and, therefore, the actual prevalence in this population could be even higher. Asymptomatic malaria represents a major challenge to malaria elimination in Honduras. Therefore, highly sensitive molecular surveillance tools such as PET-PCR that maximize malaria diagnosis are needed to reduce overall malaria burden, and to secure the progress that Honduras has achieved in the fight against malaria

5426

A PRELIMINARY ANALYSIS OF HEALTH BEHAVIORS AND ACCESS TO CARE FOR SEVERE MALARIA DISEASE AT SUSSUNDENGA-SEDE HEALTH CENTER

Dominique E. Earland[1], Albino F. Bibe[2], Vali Muhiro[3], Diocleciano Nelio[3], João Ferrão[4], Kelly Searle[1]

[1]University of Minnesota School of Public Health, Minneapolis, MN, United States, [2]Escola Secundária de Sussundenga, Manica, Mozambique, [3]Sussundenga-Sede Rural Health Center, Manica, Mozambique, [4]Consultores Associados de Manica, Manica, Mozambique

Severe malaria disease prevention is influenced by access to care, individual health behaviors, and navigation of care at health centers. Severe malaria case management rarely considers the complexity of factors and environments that cause increased morbidity and mortality associated with severe malaria disease. There is limited research about severe malaria case management in Western Mozambique, especially in rural, high transmission settings. Our aim was to quantify access to care and use of malaria prevention behaviors among individuals seeking care at the Sussundenga-Sede health center in Sussundenga, Mozambique, a rural village bordering Zimbabwe in Manica Province. We conducted a time-matched case control study from April 2022-2023. We used systematic sequential sampling to enroll 120 individuals with severe malaria disease and 120 individuals with non-malaria disease who are hospitalized at the Sussundenga-Sede health center. Cases were defined as a hospitalization with malaria tested by blood smear or positive malaria rapid diagnostic test (RDT) and one or more severe malaria symptoms. Controls were defined as a hospitalization without malaria tested by a negative blood smear or negative malaria RDT and not seeking care for conditions related to an accident. Eligible participants were: 1) older than 3 months; 2) full time residents in Manica Province; 3) had the capacity to provide consent; and 4) presented to Sussundenga-Sede health center within 72 hours of enrollment. The study excluded military members, children younger than 3 months, and pregnant women. All consenting participants completed a survey about their neighborhood level access to care, malaria prevention behaviors, and process to seek care at Sussundenga-Sede health center. The survey included a medical records abstraction tool to record severity of disease and treatment. The findings of this preliminary analysis will provide additional insight into community access to care and identify malaria health behaviors that impact seeking care for severe malarial disease.

5427

HEAVY SCHISTOSOMA MANSONI INFECTION IS ASSOCIATED WITH REDUCED RISK OF PLASMODIUM INFECTION IN SCHOOLCHILDREN IN LEMFU, DEMOCRATIC REPUBLIC OF THE CONGO

Rhyno Aubert Tshibamba Kalonji

Protestant University of Congo, Kinshasa, Congo, Democratic Republic of the

Schistosoma mansoni and Plasmodium spp. coinfection is common in the tropics. Studies on the interactions between these parasites have yielded conflicting results in the sense that S. mansoni infection is associated either with reduced or increased concurrent Plasmodium spp. infection intensity. The lack of data on the interaction between these two diseases in the Democratic Republic of the Congo (DR Congo) motivated the undertaking of the present study. An analytical cross-sectional study was conducted in two elementary schools in Lemfu. The diagnosis of S. mansoni and Plasmodium infections was made by Kato-Katz and Giemsa-stained blood drop smears techniques, respectively. The association between both infections was determined by the Chi-square test of independence. Out of 216 schoolchildren involved in the study, 93 (43.1%) were concurrently infected with both S. mansoni and Plasmodium spp., of whom 52 (56.52%) and 23 (24.7%) had light malaria parasite burden and heavy S. mansoni infection, respectively. Half (13) of those with heavy schistosomiasis had light malaria infection. Forty-two (45.16%), 35 (37.63%), and 16 (17.2%) schoolchildren had S. mansoni-P. falciparum, S. mansoni-P. malariae and S. mansoni-P. falciparum-P. malariae, respectively. Twelve-years old subjects with heavy schistosomiasis had about 6 times less risk of having concurrent malaria infection than those with light S. mansoni infection, especially with P. malariae. S. mansoni-Plasmodium spp. coinfection is common in tropics, including DR Congo where it constitutes a public health problem. Effects of S. mansoni on Plasmodium spp. seems to be dependent on the S. mansoni parasite burden and the age of the human hosts. Further studies are needed to exclude possible influence of the endemicity and transmission levels for both schistosomiasis and malaria.

5428

ASYMPTOMATIC AND SUBMICROSCOPIC MALARIA INFECTIONS IN SUGAR CANE AND RICE DEVELOPMENT AREAS OF ETHIOPIA

Water resource development projects such as dams and irrigation schemes have a positive impact on food security and poverty reduction but might result in an increased prevalence of malaria. Therefore, we assessed asymptomatic and sub-microscopic malaria in sugarcane and rice development areas of Ethiopia. We conducted two cross-sectional surveys in dry and wet seasons in irrigated and non-irrigated clusters of Arjo sugarcane and Gambella rice development areas of Ethiopia in 2019. A total of 4464 and 2176 blood samples were collected from Arjo and Gambella. A subset of 2244 microscopy-negative blood samples was analyzed by polymerase chain reaction (PCR). Multivariate logistic regression was used to estimate the association between risk factors and malaria infection. The prevalence of malaria infection by microscopy was 2.0% (88/4464) in Arjo and 6.1% (133/2176) in Gambella. In Gambella, the prevalence was significantly higher in rice-irrigated clusters (10.4% vs 3.6%) than in non-irrigated clusters, but no difference was found in Arjo (2.0% vs 2.0%). Educational level was a risk factor associated with infection in Arjo [adjusted odds ratio (aOR): 3.2; 95% confidence interval (CI) (1.27-8.16)] and in Gambella [aOR: 1.7; 95%CI (1.06-2.82)]. While the duration of stay in the area for < 6 months [aOR: 4.7; 95%CI (1.84-12.15)] and being a migrant worker [aOR: 4.7; 95%CI (3.01-7.17)] were risk factors in Gambella. Season [aOR: 15.9; 95%CI (6.01-42.04)], no ITN utilization [aOR: 22.3; 95%CI (7.74-64.34)] were risk factors in Arjo, while irrigation [aOR: 2.4; 95%CI (1.45-4.07)] and family size [aOR: 2.3; 95%CI (1.30-4.09)] were risk factors in Gambella. Of the 1713 and 531 randomly selected smear-negative samples from Arjo and Gambella analyzed by PCR the presence of Plasmodium infection was 1.2% and 12.8%, respectively. P. falciparum, P. vivax, and P. ovale were identified by PCR in both sites. In conclusion, strengthening malaria surveillance and control in project development areas and proper health education for at-risk groups residing or working in such development corridors is needed.

5429

ANTENATAL CARE SURVEILLANCE OF PLASMODIUM FALCIPARUM IN MOZAMBIQUE: FROM MALARIA TRENDS TO GENOMICS

Glória Graça Ernesto Matambisso[1], Clemente Silva[1], Dário Tembisse[1], Simone Boene[1], Henriques Mbeve[1], Nelo Ndimande[1], Eduard Rovira[2], Neide Canana[3], Bernadete Rafael[4], Sónia Enosse[3], Maria Rodriques[3], Baltazar Candrinho[4], Francisco Saúte[1], Alfredo Mayor[2]

[1]Manhica Health Research Centre (CISM), Manhica district, Mozambique, [2]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [3]Malaria Consortium (MC), Maputo, Mozambique, [4]National Malaria Control Program (NMCP), Maputo, Mozambique

Pregnant women at first antenatal care (ANC) visit may provide accessible routine information of malaria trends in the community. With the purpose of testing the viability of an ANC-based surveillance approach in Mozambique, we are recruiting pregnant women at first ANC visit (from January 2022 to December 2023) at sixty-five health facilities, in eight provinces, with low and medium-to-high intensity of malaria transmission. At this first ANC visit, clinical and demographic information are being collected together with malaria rapid diagnostic test (RDT) results. Finger-prick blood samples onto filter papers are being collected for detection and quantification of Plasmodium falciparum by real-time quantitative PCR (qPCR) and amplicon-based next generation sequencing. From January to December 2022, a total of 3.764 pregnant women were recruited. The preliminary results showed that P. falciparum positivity rate by rapid diagnostic test (PfPRRDT) was 0.8% (10/1253) in the low transmission area (Magude district) and 31.7% (796/2511) in medium-to-high transmission areas (highest in the provinces of Sofala [49.7%], followed by Nampula [44.4%] and Zambézia [42.3%] and lowest in the provinces of Gaza [7.6%], Manica [14.7%], Inhambane [15.4%]; and Niassa [33.3%] p<0.001). We are currently comparing the PfPRRDT in pregnant women with data obtained from 2-10 year-old children at health facilities and assessing the impact of antimalarial interventions in reducing parasite rates at ANC clinics. Those samples that are positive by RDT will be quantified for P. falciparum and analysed using amplicon-based next generation sequencing to identify molecular markers of resistance against artemisinin , sulfadoxine-pyrimethamine, chloroquine, P. falciparum multidrug resistance gene 1 copy number variation (pfmdr1 CNV), amodiaquine, Plasmepsin II-III CNV and markers of genetic diversity. This study will provide epidemiological and genomic information for the validation of an ANC surveillance approach to improve the programmatic performance of malaria control and elimination activities in Mozambique.

5430

SPATIO-TEMPORAL DISTRIBUTION OF MALARIA CASES IN MUTASA DISTRICT FOLLOWING MALARIA CONTROL INTERVENTION BETWEEN 2017 AND 2023

Nobert N. Mudare[1], Mukuma Lubinda[2], Tamaki Kobayashi[3], Sungano Mharakurwa[1], William J. Moss[4]

[1]Africa University, Mutare, Zimbabwe, [2]Macha Research Trust, Choma, Zambia, [3]Johns Hopkins Bloomberg School of Public Health, Mutare, MD, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Over the last decade, the incidence of confirmed malaria has declined significantly in Mutasa District. Despite a relatively good national case reporting system, detailed maps of malaria distribution have not been publicly available. In this study, monthly surveillance records over the period 2017 - 2023 of malaria burden data by PfHRP2 based rapid diagnostic tests confirmed malaria parasite positive blood specimen, were used to produce maps of malaria distribution across the District. The maps show that Plasmodium falciparum malaria incidence has a marked variation in distribution over the District. The incidence of P. falciparum malaria follows a spatial heterogeneity pattern. In the north of the district, malaria shows one seasonal peak in the period April- May of the year, whereas towards the south, the malaria cases are sporadic. This paper provides maps of

P. falciparum malaria incidence distribution in Mutasa district resolution, which may be useful to health professionals, travelers in their assessment of malaria risk in Mutasa. As incidence of malaria changes over time, regular updates of these maps are necessary.

5431

SPATIAL DYNAMICS OF MALARIA TRANSMISSION

David Smith[1], Sean L. Wu[1], John M. Henry[1], **Juliet Nsumba Nakakawa**[2], Doreen M. Ssebuliba[3], Daniel T. Citron[1], Austin R. Carter[1], Dorothy C. Echodu[4]

[1]University of Washington, Seattle, WA, United States, [2]Makerere University, Kampala, Uganda, [3]Kyambogo University, Kampala, Uganda, [4]Pilgrim Africa, Seattle, WA, United States

Malaria transmission dynamics are complex due to variations in space, time, heterogeneity, stochasticity, and other exogenous forces like the weather. These variations affect mosquito ecology and malaria transmission dynamics through blood feeding. From the Ross-Macdonald model, several individual-based models have been developed and analyzed but with little emphasis on the analysis of spatial dynamics and uncertainty. Modeling and analyzing real systems can become computationally overwhelming with parametric challenges and increasing factors from dimension, interactions, and system processes. This always leads to the development of simple but unrealistic models that give limited room for robustness. This study aims at providing a modular framework as an alternative approach to dealing with complexity that is analytically tractable. It also provides algorithms to understand mosquito ecology, parasite dispersal, mosquito dispersal on a spatial landscape, and human stratification by behavior, travel, age, sex, bed net usage, and care-seeking among others. The framework further provides a platform for quantifying and synthesizing transmission that occurs at a particular time and place by keeping track of the mosquito and human position. As a case study, we provide a three-habitat, two patches, and two human stratified model describing mosquito ecology and malaria dynamics in the modular framework. This is analyzed with steady states and reproductive numbers to prove mathematical consistency and biologically meaningful output. From this study, it is noted that the modular framework makes it easy to develop and extend this existing model to incorporate other factors including exogenous forcing, drug resistance, and vector control among others. It is also easy to modify the functional response and some basic parameters that may affect the outcome while maintaining robustness. We intend to show a model of malaria transmission in Uganda at the district level built using this framework

Malaria is a parasitosis transmitted to humans by the bite of theinfected female Anopheles. In 2020, approximately 220 million cases were reportedby WHO country members. The Democratic Republic of Congo (DRC) is the secondmost affected African country, with 15,272,767 cases reported. Three of theseplasmodial species, Plasmodium falciparum, P. malariae and P. ovale are reported but theirdistribution in the cities of Bandundu and Kikwit is poorly known. This study aims toprovide reliable and updated date on frequency and distribution of the plasmodialspecies in the study cities to improve management of malaria. To determine the frequency and distribution of the plasmodial speciescirculating in the towns of Bandundu and Kikwit. A cross-sectional study was conducted. We collected thick and thinblood smears from patients admitted in the health facilities to determine parasite loadand identify the plasmodial species involved. Measures of central tendency anddispersion of study variables were determined. The association between test positivityand study variables was tested by logistic regression and the non-parametric Kruskall-Wallis test. The parasite prevalence was of 33.1% in both cities. The study revealed 2 plasmodial species circulating in the region; P. falciparum 94.3% of cases and P. malariae 5.7% of cases. We found a statistically significant association betweengender, overnight stay under mosquito nets and malaria positive test of respectivelyOR=0.668, p=0.009 and OR=0.59, p=0.023. In conclusion, the study identified two plasmodial species, P. falciparum and P. malariathat circulate in Bandundu and Kikwit. P. falciparum being the most frequent.

5433

METHODOLOGY TO ESTIMATE DISTRIBUTION OF MALARIA CASES AMONG CHILDREN IN SUB-SAHARAN AFRICA BY SPECIFIED AGE CATEGORIES

Cornelis Winnips[1], Olorunfemi Oshagbemi[1], Pedro Lopez-Romero[1], Katalin Csermak Renner[1], Guoqin Su[2], Elodie Aubrun[1]

[1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Children in Sub-Saharan Africa (SSA) remain the most vulnerable to malaria infections and death, thus a better understanding of distribution of malaria within this subpopulation is important for the enrolment of representative populations into clinical trials. To estimate the distribution of Plasmodium falciparum (Pf) malaria among children by specified age categories (0 to <2 years, 2 to < 6 years, 6 to <12 years, ≥12 years) in SSA. We employed data on the number of cases and incidence rates of PF malaria by age group from the Institute of Health Metrics and Evaluation (GBD 2019) for 11 countries located in SSA. Different statistical distributions were fitted to observed data. The best fitting statistical distribution was used to estimate the percentage of individuals within the age bands of interest. We found that the best-fitting distribution of Plasmodium falciparum (Pf) malaria cases by prespecified age categories was derived using a combination of a log-Normal and Weibull distribution. According to this distribution of Pf malaria was 15.4% for ages 0 to <2 years, 30.5% for 2 to < 6 years, 17.6% for 6 to <12 years, and 36.5% for ≥12 years based on data from selected countries in SSA. In conclusion, our results have important implications for the current drive by regulators to ensure the representativeness of real-world populations in clinical trials evaluating the safety and efficacy of medication exposure. The theoretical distributions of Pf malaria reported in this study will help guide researchers in ensuring that children are appropriately represented in clinical trials and other interventions aiming to address the current burden of malaria in SSA.

5434

PREVALENCE OF ASYMPTOMATIC AND SUBMICROSCOPIC MALARIA INFECTIONS AMONG HIV PATIENTS IN YAOUNDE, CAMEROON

Peter T. N. Niba[1], Laura A. Tata[1], Tsiambom Monju[2], Akindeh M. Nji[1], Innocent M. Ali[3], Jean P. K. Chedjou[4], Abdel A. Selly-Ngaloumo[1], Calvino T. Fomboh[1], Michelle L. M. Bakam[1], Liwang Cui[5], Gillian Stresman[5], Jude D. Bigoga[1], Michael Alifrangis[6], Wilfred F. Mbacham[1]

[1]University of Yaounde I, Yaounde, Cameroon, [2]School of Health Sciences, Catholic University of Central Africa, Yaounde, Cameroon, [3]University of Dschang, Dschang, Cameroon, [4]University of Buea, Buea, Cameroon, [5]University of South Florida, Tampa, Florida, FL, United States, [6]University of Copenhagen, Copenhagen, Denmark

Malaria remains a major public health problem in Cameroon despite the scale-up of interventions. Asymptomatic carriers are important reservoirs

for transmitting malaria parasites to susceptible human hosts. Malaria and HIV infections are known to interact bi-directionally and synergistically with each other. Hence, this study aimed to determine the prevalence of asymptomatic and submicroscopic malaria infections among HIV patients in Yaounde, Cameroon. A cross-sectional hospital-based study was conducted among HIV patients attending the antiretroviral clinic at the District Hospital Cité Verte, Yaounde, in 2018. Malaria parasite detection was done using microscopy and rapid diagnostic test (RDT). Parasite DNA was extracted from the Whatman 903 filter papers spotted with whole blood. Molecular detection was done by nested PCR (n-PCR) targeting the 18S rRNA. A total of 240 asymptomatic samples were successfully genotyped. The prevalence of asymptomatic malaria infections by microscopy, RDT and n-PCR was 23.8% (57/240), 10.8% (26/240), and 16.3% (39/240), respectively. Submicroscopic malaria infections were identified in 14.5% (26/179) of the study participants. Moreover, the sensitivities, specificities and overall diagnostic accuracies using n-PCR as the standard method were: microscopy (35.90%, 78.61%and 71.67%) and RDT (33.33%, 93.53%and 83.75%). The Cohen's Kappa value for microscopy, rapid diagnostic test, and n-PCR was 0.448 (P<0.0001). The performance of RDT was higher (AUC=0.634, P=0.008) when compared with microscopy (AUC=0.573, P=0.152). Among the Plasmodium species identified, Plasmodium falciparum accounted for 50.0% (17/34) of asymptomatic infections, followed by P. malariae and P. ovale with 26.5% (9/34) and 23.5% (8/34), respectively. This study reported a moderate prevalence of asymptomatic and submicroscopic malaria infections among HIV patients. It was observed that RDTs performed better than microscopy in the identification of asymptomatic malaria infections. There is a need to reinforce training in microscopy due to the high number of false positives registered.

5435

EXPLORING THE COST EFFECTIVENESS OF PROACTIVE CASE DETECTION IN HARD-TO-REACH, HIGH INCIDENCE COMMUNITIES FROM A COHORT STUDY IN SOUTHEAST MADAGASCAR

Joseph Lewinski[1], James Hazen[1], Mahery Rebaliha[2], Virginie Ralisoa[2], Elanirina Andrianoelivololona[2], Benjamin Rice[3]

[1]Catholic Relief Services, Baltimore, MD, United States, [2]Catholic Relief Services, Antananarivo, Madagascar, [3]Princeton University, Princeton, NJ, United States

Passive, untargeted malaria control strategies may fail to reach and manage cases in hard-to-reach communities. Investments in proactive approaches targeted at these communities may enable progress towards malaria elimination goals. However, questions remain as to cost-effectiveness and scalability. We studied a cohort of 500 households (2485 individuals) from a high-incidence district (Mananjary) in southeast Madagascar. Households were defined as hard-to-reach if they had low access to treatment at healthcare facilities, community case management, and prevention coverage. Beginning in July 2021, bimonthly testing and treatment were provided to enrolled households via mobile clinic. At baseline, less than 3% of infected individuals received treatment from a healthcare facility or community health worker, and prevalence varied from 15.3% to 60.4% among communities. From the monthly screening data (23,632 total observations to date), we estimate cost-effectiveness in terms of the cost per individual screened, cost per infection treated, and explore potential savings from cases averted. During follow-up, we observed a mean decline in prevalence of 58.6% among enrolled households to date. We leverage this empirical data and mathematical modeling to explore scalability from two perspectives. First, we model susceptibility of proactive case detection approaches to disruptions, such as extreme weather events. Second, we model the extent and sustainability of declines in incidence achievable at varying levels of coverage at the community level. The optimal screening frequency and coverage to maximize cost-effectiveness will be presented. Results demonstrate the need to invest in more proactive case management in hard-to-reach areas to achieve basic control goals and set foundations for elimination efforts.

5436

GENETIC DIVERSITY AND GENOTYPE MULTIPLICITY OF PLASMODIUM FALCIPARUM INFECTION IN PATIENTS WITH UNCOMPLICATED MALARIA IN CHEWAKA DISTRICT, ETHIOPIA

Abdulhakim Abamecha[1], Hassan ElAbid[2], Daniel Yilma[1], Wondimagegn Addisu[1], Achim Ibenthal[3], Abebe Genetu Bayih[4], Harald Noedl[5], Delenasaw Yewhalaw[1], Mohieddine Moumni Moumni[2], Alemseged Abdissa[4]

[1]Jimma University, Jimma, Ethiopia, [2]Laboratory of Cellular Genom ics and Molecular Techniques for Investigation, Faculty of Sciences, Moulay Ismail University,, Meknès, Morocco, Morocco, [3]Faculty of Science and Art, HAWK University, Gottingen, Germany, [4]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [5]Malaria Research Initiative Bandarban (MARIB), Vienna, Austria

Genetic diversity in Plasmodium falciparum poses a major threat to malaria control and elimination interventions. Characterization of the genetic diversity of P. falciparum strains can be used to assess intensity of parasite transmission and identify potential deficiencies in malaria control programmes, which provides vital information to evaluating malaria elimination efforts. In this study, we investigated the P. falciparum genetic diversity and genotype multiplicity of infection in parasite isolates from cases with uncomplicated P. falciparum malaria in Southwest Ethiopia. A total of 80 P. falciparum microscopy and qPCR positive blood samples were collected from study participants aged six months to sixty years, who visited the health facilities during the evaluation of a therapeutic efficacy study of arthemeter-lumefantrine from September-December, 2017. Polymorphic regions of the msp-1 and msp-2 were genotyped by nested polymerase chain reactions (nPCR) followed by gel electrophoresis for fragment analysis. Of 80 qPCR-positive samples analyzed for polymorphisms on msp-1 and msp-2 genes, the efficiency of msp-1 and msp-2 gene amplification reactions with family-specific primers were 95 % and 98.8%, respectively. A total of 29 msp alleles (10 for msp-1and 19 for msp-2) were detected. In msp-1, K1 was the predominant allelic family detected in 47.7% (42/88) of the samples followed by Mad20 and RO33. For msp-2, the frequency of FC27 and IC/3D7 were 77% (57/74) and 76% (56/74), respectively. Eighty percent (80%) of isolates had multiple genotypes and the overall mean multiplicity of infection was 3.2 (95% CI: 2.87- 3.46). The heterozygosity index was 0.43, and 0.85 for msp-1 and msp-2, respectively. There was no significant association between multiplicity of infection and age or parasite density. The study revealed high levels of genetic diversity and mixed-strain infections of P. falciparum populations in Chewaka district, Ethiopia; reflecting both the endemicity level and malaria transmission remained high and more strengthened control efforts are needed in Ethiopia.

5437

ULTRA-DEEP AMPLICON SEQUENCING OF HIGHLY POLYMORPHIC NOBLE MARKERS OF PLASMODIUM FALCIPARUM SHOWS DECLINING OF MALARIA TRANSMISSION IN ETHIOPIA

Abeba G. Reda

Ethiopian Public Health Institute (EPHI), Addis Ababa, Ethiopia

Plasmodium falciparum is the most serious, genetically complex, and fastest-evolving malaria parasite. This study was initiated to explore the population structure, to generate relatedness networks, multiple infections, and heterozygosis of the P. falciparum population in three malaria-endemic sites northern, eastern, and southern Ethiopia. The participants of the study were patients who were recruited for uncomplicated falciparum malaria therapeutic efficacy tests from October 2015 to December 2015 and November 2019 to December 2019. Quantitative real-time polymerase chain reaction (QRT-PCR)-confirmed Dry blood spot samples were analyzed by ultra-deep amplicon sequencing to detect P. falciparum amp-1, csp, cpp, cpmp, and msp7 genes. Population structure was analyzed using STRUCTURE software. Identity-by-state (IBS) was calculated as a measure

of parasite relatedness and used to generate relatedness networks. 183 were successfully sequenced by deep amplicon sequence. Five genes, ama 1, csp, cpp, cpmp and msp7 genes were successfully sequenced and respectively detected in 179(97.8%), 181(98.9%) and 179 (97.8%),178 (97.3%) and 160.(87.4%) of the samples from the three sites. Multiple of infection (MOI) of each marker was 1.2, 1.06, 1.16, 1.14, and 0.99, respectively. The overall MOI was 1.38. The expected heterozygosity index (He) of each marker was 0.25, 0.15, 0.26, 0.24, and 0.36, respectively. No population structure was evident for suggesting high transmission and gene flow among the three sites (P > 0.05). In conclusion, low genetic diversity in the P. falciparum population and the overall declining trend were observed as demonstrated by the lower Multiple of infection and heterozygosis suggesting better progress in malaria control in the regions.

5438

GENETIC DIVERSITY OF PLASMODIUM FALCIPARUM AND TRANSMISSION PATTERNS IN FOREST-GOING POPULATIONS IN SOUTHERN LAO PDR

Ying-An Angie Chen[1], Francois Rerolle[2], Eric Vickers[3], Emily Dantzer[2], Bouasy Hongvanthong[4], Andrew Lover[5], Hsiao-Han Chang[1], Adam Bennett[6], Bryan Greenhouse[3]

[1]Institute of Bioinformatics and Structural Biology, College of Life Sciences and Medicine, National Tsing Hua University, Hsinchu, Taiwan, [2]Malaria Elimination Initiative, The Global Health Group, University of California, San Francisco, San Francisco, CA, United States, [3]EPPIcenter Research Program, Division of HIV, Infectious Diseases and Global Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA, United States, [4]Center for Malariology, Parasitology and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic, [5]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts Amherst, Amherst, MA, United States, [6]PATH, Seattle, WA, United States

The Lao People's Democratic Republic (PDR) is approaching malaria elimination and the remaining cases are increasingly clustered in forest areas in the southern provinces. To assess parasite transmission patterns in this area, 53 Plasmodium falciparum (Pf) positive cases detected through test and treat campaigns between December 2017 and November 2018 were sequenced, targeting 180 diverse microhaplotypes. Two R packages, Moire and Dcifer, were applied to assess the complexity of infections (COI), within-host parasite relatedness, and inter-sample relatedness. Genomic data were integrated with survey data to investigate the associations between parasite genetic diversity and case characteristics. Parasite genomic analysis showed that 32% of the cases (17/53) were polyclonal infections (COI = 2-3), and 68% (36/53) of cases were infected by a single parasite clone (COI = 1). Most of the polyclonal samples showed evidence of strong within-host relatedness (mean $\hat{r}$ = 0.7), suggesting that cotransmission rather than superinfection was primarily responsible for maintaining polyclonality in this low transmission setting. We identified five genomic clusters with high pairwise relatedness ($\hat{r}$ = 0.7-0.9) in forest fringe villages in Pathoomphone (PT) district; this area had the highest test positivity and forest activity. There were four smaller clusters of 2-3 cases linking Moonlapamok (MP) and PT districts, with a lower degree of genetic relatedness (mean $\hat{r}$ = 0.58) or greater sampling time difference (> two months), suggesting cross-district transmission, possibly on a longer time scale. Among 53 positive cases, 81.1% (43/53) were infected by genetically linked parasites, and they were primarily male adults (median aged 27) detected through a focal test and treat intervention specifically targeting forest-goers. Transmission clusters identified in this study provide useful information for understanding malaria parasite transmission dynamics in this highly mobile forest-going population and targeting of remaining foci, where there is stronger evidence of ongoing local transmission.

5439

GENETIC DIVERSITY OF PLASMODIUM FALCIPARUM AND GENETIC PROFILE IN CHILDREN WITH ACUTE UNCOMPLICATED MALARIA IN CAMEROON

Theresia Njuabe Metoh[1], Jun-Hu Chen[2], Philip Fongah[3], Xia Zhou[4], Roger Somo-Moyou[5], XiaoNong Zhou[6]

[1]University of Bamenda, Bamenda, Cameroon, [2]NIPD CDC, Shanghai, China, [3]ITC Enschede, University of Twenty, Hengelosestraat 99, 7514 AE Enschede, Hengelosestraat, Netherlands, [4]National Institute of Parasitic Dis eases, Chinese Centre for Disease Control and Prevention, Shanghai 200025, People's Republic of China., National Institute of Parasitic Diseases (NIPD-CDC, China, [5]University of Yaounde I, Yaounde, Cameroon, [6]National Institute of Parasitic Dis eases, Chinese Centre for Disease Control and Prevention, Shanghai 200025, People's Republic of China, Shanghai, China

Malaria is a major public health problem in Cameroon. Genotyping of malaria parasite population is essential for understanding the mechanism underlying malaria pathology and to determine parasite clones profile in an infection, for proper malaria control strategies. The objective of this study was to perform a molecular characterization of Plasmodium falciparum genetic markers and to determine allelic distribution with their influencing factors valuable to investigate malaria transmission dynamics in Cameroon. Merozoite Surface Protein-1 (MSP-1) and Merozoite Surface Protein-2(MSP-2) revealed greater parasite diversity than Glutamate-Rich Protein (GLURP). Of 350 isolates analysed, a total of 16 different MSP-1 genotypes were identified, including K1, MAD20 and RO33 allelic families. A peculiarity of this study is that RO33 revealed a monomorphic pattern among the Pfmsp-1 allelic type. A total of 27 different Pfmsp-2 genotypes, were recorded of which 15 belonged to the 3D7-type and 12 to the FC27 allelic families. The analysis of the MSP-1 and MSP-2 peptides reveals that the region of the alignment corresponding K1 polymorphism had the highest similarity in the MSP1and MSP2 clade followed by MAD20 with 93% to 100% homology. Therefore, population structure of P. falciparum isolates from Cameroon is identical to that of other areas in Africa, suggesting that vaccine developed with k1 and MAD20 of Pfmsp1 allelic variant could be protective for Africa children. The MOI was significantly higher ($P<0.05$) for Pfmsp-2 loci (3.82), as compared to Pfmsp-1 (2.51) and heterozygotes ranged from 0.55 for Pfmsp-1 to 0.96 for Pfmsp-2. High genetic diversity and allelic frequencies in P. falciparum isolates indicate a persisting high level of transmission. This study advocate for an intensification of the malaria control strategies in Cameroon

CYP3A4 GENE VARIANTS AMONG RESIDENTS OF LAKE VICTORIA REGION, KENYA, 2013

Kelvin B. Musyoka[1], Chim W. Chan[1], Protus Omondi[1], Caroline Kijogi[2], Evelyn Marie Gutiérrez Rico[2], Takatsugu Okai[1], Mtakai Ngara[3], Wataru Kagaya[1], Masahiro Hiratsuka[2], Achyut K. C[3], Jesse Gitaka[4], Akira Kaneko[3]

[1]Department of Parasitology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan, [2]Laboratory of Pharmacotherapy of Life-Style Related Diseases, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan, [3]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden, [4]Directorate of Research and Innovation, Mount Kenya University, Thika, Kenya

Precision medicine approaches in Africa need to be driven by native population data. Cytochrome P450 enzymes, the main drug-metabolizing enzymes in humans, therefore, must be better characterized in the African population. Cytochrome P450 3A4 (CYP3A4) significantly contribute to inter-individual variation in drug metabolism and is involved in the metabolism of about 30% of clinically used drugs, including the antimalarials lumefantrine and halofantrine. We explored CYP3A4 polymorphisms in residents of the Lake Victoria basin where malaria is highly endemic. We used 136 archived DNA samples collected in 2013 during malaria cross-sectional surveys from adults resident in the four islands (Takawiri, Mfangano, Ngodhe, Kibuogi, and Ngodhe) in the Lake Victoria region and a coastal mainland (Ungoye). We used polymerase chain reaction

(PCR) amplification and sequencing to explore the genetic variation in the ~800bp of the 5-upstream region and all thirteen exons, including flanking introgenic regions of the CYP3A4 gene. Human Cytochrome P450 Allele Nomenclature Database and dbSNP were utilized to identify variants. Analysis of molecular variance (AMOVA) within and among the population was carried out using GeneAlex version 6.5 and a p-value of <0.05 was considered statistically significant. We identified 14 single nucleotide polymorphisms (SNPs), including rs4986907 (1.5%) and rs2740574 (81) promoter polymorphism. Most SNPs were introgenic at varying frequencies, lowest in Mfangano (2.0%) and highest in Ungoye (77.8%). Based on AMOVA, a lower proportion of variation among populations (8%) was observed as compared to variation within the population (92%, p<.001). In addition, we mapped an introgenic SNP, rs3735451, involved in hydroxychloroquine metabolism. To our knowledge this is the first study in Kenya to genotype the entire CYP3A4 variation which provides a foundation for future pharmacogenetic studies. Our work contributes to the data needed to improve precision medicine approaches in Africa.

5441

PLASMODIUM FALCIPARUM WITH PFHRP2 AND PFHRP3 GENE DELETIONS IN ASYMPTOMATIC MALARIA INFECTIONS IN THE LAKE VICTORIA REGION, KENYA

Takatsugu Okai[1], Chim Wai Chan[1], Wataru Kagaya[1], Protus Okwat Omondi[1], Kelvin Brian Musyoka[1], James Kongere[2], Jesse Gitaka[3], Akira Kaneko[1]

[1]Osaka Metropolitan University, Osaka-city, Japan, [2]KEMRI / Nagasaki University Institute of Tropical Medicine, Homa Bay county, Kenya, [3]Mount Kenya University, Nairobi, Kenya

As an important component in early diagnosis and treatment of malaria, rapid diagnostic tests (RDTs) are easy to use and can provide results in as few as 15 minutes. For diagnosis of Plasmodium falciparum, RDTs targeting the P. falciparum histidine rich protein 2 (PfHRP2) are widely used. Recently, reports of P. falciparum strains lacking PfHRP2 and structurally similar PfHRP3 have led to concern about the usefulness and reliability of PfHRP2-based RDTs. The aim of this study was to detect the presence of P. falciparum with pfhrp2/3 gene deletions in the area around Lake Victoria, Homa Bay County, Kenya. Dried blood spot samples were collected during four cross-sectional malaria surveys of school children between September 2018 and January 2020. RDT negative but PCR positive (n=445) samples were selected for analysis. PCR amplifications of two different single-copy genes (msp1 and msp2) indicated that 125 (28.1%) samples had sufficient P. falciparum DNA for detection of pfhrp2/3 gene deletions. PCR amplifications of the region between exons 1 and 2 of pfhrp2 and pfhrp3 showed that 11.2% (n=14), 7.2% (n=9), and 12.8% (n=16) of the examined samples harbored pfhrp2, pfhrp3, and pfhrp2/3 double deletions, respectively. P. falciparum with pfhrp2/3 double deletions were found in all surveys. While the presence of P. falciparum with pfhrp2 deletions in the study area was identified in 2014, this study reveals for the first time the presence of both parasites with pfhrp3 and parasites with pfhrp2/3 double deletions in Kenya. Although the study was not designed to determine the prevalence of P. falciparum with pfhrp2/3 deletions, the presence and persistence of these parasites highlight the need to monitor and evaluate the performance of PfHRP2-based RDTs currently in use.

5442

POPULATION AND EVOLUTIONARY GENETICS OF AMA1 GENE IN CAMEROONIAN PLASMODIUM FALCIPARUM ISOLATES

Joseph Hawadak, Loick Pradel Kojom Foko, Rodrigue Roman Dongang Nana, Vineeta Singh

National Institute of Malaria Research, New Delhi, India

Antigenic variation associated to genetic diversity in global Plasmodium falciparum apical membrane antigen-1 (PfAMA-1) is a major impediment to broadly effective malaria vaccine design. Here, we report the first study on genetic diversity and natural selection of PfAMA-1 in P. falciparum isolates from Cameroon. A total of 328 P. falciparum PCR-positive samples collected in 2016 and 2019 from five localities of Cameroon were analysed. Ectodomain coding fragment of PfAMA-1 gene was amplified and sequenced. Polymorphic profile and natural selection were analysed using MEGA 11.0 and DnaSP6 software, PAML package and Datamonkey sever. A total of 108 distinct haplotypes were found in 208 P. falciparum isolates with considerable nucleotides (π = 0.0161) and haplotype (Hd = 0.976). diversity Most amino acid substitution detected were scattered in the ectodomain domain I and few specific mutations viz P145L, K148Q, K462I, L463F, N471K, S482L, E537G, K546R and I547F were seen only in Cameroonian PfAMA-1 isolates. Five statistically reliable positively selected codon sites (P145L, S283L, Q308E/K, P330S and I547F) were identified which overlapped with predicted B-cell epitopes and red blood cell (RBC) binding sites suggesting their potential implication in host immune pressure and parasite-RBC binding complex modulation. Evidence of departure from neutrality towards positive diversifying selection was observed (Taj D =2.05824, P < 0.05). The Cameroonian P. falciparum population indicated a moderate level of genetic differentiation compared with global sequences with exception from Vietnam and Venezuela. Our findings provide baseline data on existing PfAMA1-1 gene polymorphisms in Cameroonian field isolates which will be useful information on malaria vaccine design.

5443

GENETIC DIVERSITY AND MOLECULAR EVOLUTION OF PLASMODIUM VIVAX DUFFY BINDING PROTEIN AND MEROZOITE SURFACE PROTEIN I IN NORTHWESTERN THAILAND

Parsakorn Tapaopong

Mahidol University, Bangkok, Thailand

The local diversity and population structure of malaria parasites vary across different regions of the world, reflecting variations in transmission intensity, host immunity, and vector species. This study aimed to use amplicon sequencing to investigate the genotypic patterns and population structure of P. vivax isolates from a highly endemic province in Thailand during 2015-2021. Amplicon deep sequencing was done on 70 samples for the 42-kDa region of PvMSP1 and domain II of PvDBP. Unique haplotypes were identified and a network constructed to illustrate genetic relatedness in northwestern Thailand. Overall, 16 and 40 unique haplotypes were identified in PvDBPII and PvMSP142kDa, respectively. Nucleotide diversity was higher in PvMSP142kDa than in PvDBPII (π = 0.027 and 0.012) as well as haplotype diversity (Hd = 0.962 and 0.849). Significant positive values of neutrality tests were observed in both PvMSP142kDa (dN-dS = 2.87, p < 0.05) and PvDBPII (Fu and Li's D* and F* = 1.6421 and 1.7078, p < 0.05). A lower recombination rate was found in PvDBPII, while the PvMSP142kDa showed strikingly higher levels of genetic differentiation (Fst) in northwestern Thailand versus other regions (0.2761-0.4881). Based on the two gene markers, the genetic diversity of P. vivax in northwestern Thailand was influenced by host immunity and evolved under the balancing selection. The PvMSP142kDa exhibited higher variation and showed genetically specific signatures in a certain area, while PvDBPII is more likely to be a candidate for strain-transcending vaccines due to its fewer genetic polymorphisms. Findings from this study provide an understanding of P. vivax population structure and the evolutionary force on vaccine candidates. They also established a new baseline for tracking future changes in P. vivax diversity in the most malarious area of Thailand.

5444

PREDICTING THE GENETIC SIGNATURES OF DRY SEASON AESTIVATION AMONG MALARIA TRANSMITTING MOSQUITOES

Rita Mwima[1], Tin-Yu Jonathan Hui[2], Austin Burt[2]

[1]Uganda Virus Research Institute, Entebbe, Uganda, [2]Imperial College London, Silwood Park, Berkshire, United Kingdom

Direct evidence suggests that aestivation, a form of dormancy, contributes to Anopheles coluzzii's dry season (DS) survival and its re-establishment

at the next rainy season (RS), but finding a handful of such mosquitoes precluded any opportunities for quantitative essay or parameter estimation. This work uses an indirect (i.e., genetic) approach as a means to estimate the two seasons' breeding sizes as well as the aestivating sizes, in particular, utilising signals from temporal allele frequency dynamics. We mathematically make derivations that the magnitude of drift is dampened at early RS when previously aestivating individuals reappear. This has a severe impact on temporal effective population size () estimates, that the DS breeding size is overestimated by a factor of , where is the aestivating proportion when two samples are from consecutive RS. In fact, sampling the breeding individuals at three consecutive seasons starting from RS is sufficient to estimate the three sizes. This method does not require sampling aestivating individuals, which is the biggest challenge in most experiments. We apply the method to a published An. coluzzii dataset collected from Thierola, Mali between 2008 and 2010. The estimated breeding sizes are 658 and 61 for the first year, with an aestivating size of 580 (. While information is lacking for the second year, precise estimates are obtained for the DS size (59) and the composite parameter (51%). Further, the DS breeding sizes for both years are significantly larger than 0, suggesting the coexistence of reproducing and aestivating populations in the DS. Extensive simulations are run to verify our derivations.

Better understanding of the diversity of molecular interactions and mechanisms underlying RBC invasion phenotypes in natural endemic malaria parasites will facilitate target identification and prioritization for vaccine or drug development against blood stage infection in malaria. Current understanding of invasion ligands is limited to the well characterized erythrocyte binding (EBAs) and reticulocyte homolog (Rhs) gene families. To uncover the wider and complex repertoire of genes associated with invasion phenotype diversity, RBC invasion phenotypes and transcriptome profiles were simultaneously investigated in schizont-stage preparations of Plasmodium falciparum isolates from uncomplicated malaria cases from endemic sites in Cameroon. RBC invasion phenotypes were determined for 63 samples using two-color flow cytometry-based invasion assays against RBCs treated with standard proteases: Neuraminidase (Nm), Trypsin (Tp) and Chymotrypsin (Ch). The transcriptome profiles of a random set of 16 samples were determined by deep RNA sequencing on Illumina NextSeq550. The Cameroonian isolates showed a wide diversity of RBC invasion phenotypes. More than 75% were able to invade Ch treated RBCs but not Nm treated RBCs, representing alternative or sialic acid (SA)-independent pathways of RBC invasion and corroborating previous endemic reports. Genome-wide transcript levels were determined for 5746 genes, of which ~78% were from schizont stages. Two distinct clusters belonging to SA-dependent and SA-independent parasite populations was obtained by data reduction with principal component analysis, mirroring the invasion phenotypes data. Differential analysis of gene expression between the two clusters revealed multiple merozoite-surface, export, and virulent proteins to be up-regulated in the SA-independent parasite isolates, in addition to the EBAs and Rhs. Most of the upregulated genes have been described to have structural and physiological relevance to immune interactions against parasites in endemic settings. These proteins can be further explored as priority targets for next generation vaccine development.

Malaria is a global public health priority causing over 600,000 deaths annually, mostly young children living in Sub-Saharan Africa. Molecular surveillance can provide key information for malaria control, such as the prevalence and distribution of antimalarial drug resistance. However, genome sequencing capacity in endemic countries can be limited. Here, we have implemented an end-to-end workflow for Plasmodium falciparum genomic surveillance in Ghana using the Oxford Nanopore Technologies (ONT) handheld MinION device, targeting antimalarial resistance markers and the leading vaccine antigen, circumsporozoite protein (csp), in a multiplex PCR amplicon sequencing approach. Sample collection, sequencing and analysis was undertaken in Accra and the Upper East Region, using the latest ONT chemistry and a commercial gaming laptop computer. An open-access Nextflow informatics pipeline was developed for real-time genetic variant calling, called nano-rave (the nanopore rapid analysis and variant explorer). The workflow was rapid, robust, accurate, affordable and straightforward to implement. We found that P. falciparum parasites in Ghana had become largely susceptible to chloroquine, with persistent sulfadoxine-pyrimethamine (SP) resistance, and no evidence of resistance to the current front-line antimalarial, artemisinin. Multiple single nucleotide polymorphism differences from the vaccine csp sequence were identified at high frequencies, though their clinical significance is uncertain. These results agreed closely with Illumina sequence data from the same regions. We will present further development and expansion of this ONT amplicon sequencing platform, including the addition of a new variant calling software that can detect minor variants in mixed infections, and extension of the method to dried blood spot samples. Overall, this ongoing study demonstrates the potential utility and feasibility of malaria genomic surveillance using nanopore sequencing, and provides methodological and analytical tools for its establishment in endemic settings.

GYPB DELETION VARIANTS (DEL1 AND DEL2) DISTRIBUTION AMONG GHANAIAN POPULATIONS AND RELATIONSHIP WITH MALARIA SUSCEPTIBILITY

Dominic SY Amuzu[1], Lucas N. Amenga-Etego[1], Kirk A. Rockett[2], Collins M. Moranga[1], Nancy K. Nyakoe[1], Ellen M. Leffler[3], Christina Hubbart[4], Kate Rowlands[4], Anna Jeffreys[4], Alfred Amambua-Ngwa[5], Dominic P. Kwiatkowski[6], Gordon A. Awandare[1]

[1]West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, [2]Wellcome Sanger Institute, Wellcome Genome Campus, Oxford, United Kingdom, [3]Department of Human Genetics, University of Utah,, Salt Lake City, UT, United States, [4]Wellcome Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [5]MRC Unit The Gambia at London School of Hyiene and Tropical Medicine, Fajara, Gambia, [6]Big Data Institute, University of Oxford, Oxford, UK, Oxford, United Kingdom

Glycophorins play an important role in the mediating the invasion of erythrocytes by Plasmodium falciparum, and thus variation in the glycophorin gene locus has implications for malaria susceptibility. In West Africa, the most common variants are deletions of the whole GYPB gene.

The allele frequencies of these GYPB large deletions have been previously estimated to be between 0.05-15% for GYPB DEL1 and DEL2 respectively in populations in Africa but the effect of these deletions on malaria susceptibility is still unknown. To understand this, we genotyped for GYPB DEL1 and DEL2 alleles to facilitate the identification of phenotypes for functional characterization of these variants and malaria disease outcomes. In this study, the distribution and the allele frequency of GYPB DEL1 and DEL2 among Ghanaian populations were determined using a high throughput assay for the identification of these deletions. We genotyped over 2000 samples from different ethnicities in Ghana. Overall, the allele frequency of GYPB deletions was observed to be 0.072% and 0.032% for GYPB DEL1 and DEL2 respectively. The highest allele frequencies for GYPB DEL1 and DEL2 were in the Zambrama (41.67%) and Mo (20.59%). In addition, we observed that GYPB DEL1 or DEL2 allele was associated with absence of malaria parasites and self-reported absence of malaria re-infections. This is the first comprehensive large survey on the distribution of the Glycophorin B deletion variants using a high-throughput assay to genotype different populations. This allows for further experimental work to be done using these ethnic groups with relatively high GYPB DEL1 or DEL2 variants within the Ghanaian population, and for stratification of genetic association studies to understand the role of this region in malarial disease. This study also will pave the way for GYPB DEL1 and DEL2 surveys in other malaria endemic populations in relation to malaria susceptibility.

INCREASED FREQUENCY OF PFHRP2-DELETED PLASMODIUM FALCIPARUM IN THE PERUVIAN AMAZON IS NOT EXPLAINED BY SELECTION OF THE GENE DELETION

Erick Figueroa-Ildefonso[1], Hugo Valdivia[2], Eline Kattenberg[3], Christopher Delgado-Ratto[4], Anna Rosanas-Urgell[3], Dionicia Gamboa[5]

[1]Laboratorio de Malaria: Parasitos y Vectores, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]U.S. Naval Medical Research Unit No. 6 (NAMRU-6), Lima, Peru, [3]Department of Biomedical Sciences, Institute of Tropical Medicine Antwerp, Antwerp, Belgium, [4]Global Health Institute, University of Antwerp, Antwerp, Belgium, [5]Laboratorio de Malaria: Parasitos y Vectores, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia and Instituto de Medicina Tropical "Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, Lima, Peru

Since the first report of the pfhrp2 gene deletion (pfhrp2-) in Plasmodium falciparum parasites from the Peruvian Amazon, the deletion has become more frequent. Recently, this deletion has been reported in other countries within and outside of South America, threatening malaria control efforts. In regions where the deletion surpass 5% prevalence, WHO recommends using alternative diagnostic tools to hrp2-based RDTs. The use of RDTs has been suggested as a main factor driving the increase of pfhrp2- parasites in Ethiopia. However, those findings cannot be extrapolated to countries like Peru, where malaria diagnosis is mainly performed by microscopy. In this regard, using PCR, we evaluated if the frequency of the deletion has increased in samples collected between 2013-2017 (n=172). Subsequently, we performed the genomic analysis of P.f with time, for what we added to our genomic data (n=41), available genomes from additional years (n total=100, 2006-2018). Thus, we characterized the population structure and analyzed the genomes looking for signatures of selection. Our findings showed that pfhrp2- parasites increased to >76%. In addition, pfhrp2- and pfhrp2+ parasites are two different clonal populations that would have expanded after a bottleneck around 2010, when PAMAFRO interventions ceased. We could not detect any signature of selection in the genomic region close to the deletion with Tajima's D test neither with LD-based methods. However, parasites with and without pfhrp2 deletions share common regions with signals of be under balancing selection in genes of the var family, which are involved in parasite interaction with immune system of the human host. Furthermore, pfhrp2-deleted parasites presented unique candidate regions to be under selection that include a transcription factor involved in the gametocyte differentiation (AP2-G) and a gene suggested to be associated with artemisinin resistance (FP2A). These findings suggest that the pfhrp2 deletion has not been under selective pressure in Peru, and its increase in frequency could be consequence of this parasite's drug sensitivity profile and/or increased transmission success.

Plasmodium malariae (Pm) is already prevalent in certain African regions and expected to become more prevalent as P. falciparum (Pf) is eliminated. Like other non-falciparum malaria species, Pm usually causes less clinically severe infections than Pf, but it can cause chronic infections. To better understand this neglected but widespread malaria pathogen, we performed hybrid capture sequencing of 42 Tanzanian Pm isolates collected as part of the Molecular Surveillance of Malaria in Tanzania (MSMT) project in 2021 and Transmission from Submicroscopic Malaria in Tanzania (TranSMIT) project 2018-2021. These isolates span fourteen different regions representing malaria transmission strata ranging from very low (e.g. Kilimanjaro) to very high (e.g. Tabora), with regional Pm positivity rates ranging from 0.2% to 4.5%. Fourteen isolates (33%) are Pm mono-infections, while the others are mixed with Pf. Positive isolates were identified using a semi-quantitative Pm-specific 18S qPCR, with a CT of 35 as the upper limit for sequencing. Library preparation and hybrid capture were performed using a custom Twist Bioscience kit prior to sequencing on an Illumina NovaSeq 6000. This method enables us to generate high coverage sequences spanning the entire Pm genome. Initial experiments in six isolates showed enrichment, with an average of 78% of reads mapping to Pm (range 64% - 88%). Using this method, we are able to generate high-quality Pm sequences even in lower-density isolates and Pm/Pf mixed infections. Using these genome sequences, we will present the first in-depth, country-wide population genomic analysis of this understudied and poorly understood malaria species.

EXPLORING HOW TRANSMISSION INTENSITY, SAMPLING, AND HUMAN MOBILITY IMPACT OUR ABILITY TO MEASURE GENETIC RELATEDNESS ACROSS PLASMODIUM FALCIPARUM POPULATIONS

Sophie Berube[1], Rohan Arambepola[1], Betsy Freedman[2], Steve Taylor[3], Wendy O'Meara[4], Andrew Obala[5], Amy Wesolowski[1]

[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [2]Duke University Medical Center, Durham, NC, United States, [3]Duke University, Durham, NC, United States, [4]Duke Universtiy, Durham, NC, United States, [5]Moi University, Eldoret, Kenya

Malaria parasite genomic data are increasingly used to identify highly related infections which can illuminate epidemiological, spatial, or temporal factors associated with patterns of transmission. However, in settings with moderate to high transmission, measuring relatedness between infections is inhibited by complex infections, overall high forces of infection, and diverse parasite populations. It is not clear how these factors impact the ability to measure between-infection relatedness under various conditions including different sampling schemes, patterns of missing data, and levels of human mobility. Further investigation is required to determine which patterns of relatedness we expect to be able to reliably detect with high quality, densely sampled genomic data in a high transmission setting. We evaluated two identity-by-state measures of relatedness and applied them to amplicon

deep sequencing data collected as part of a longitudinal cohort from an area of high transmission in Western Kenya. We observed evidence of temporal structure, but not of fine-scale spatial structure in the cohort data. To explore factors associated with the lack of spatial structure in these data, we constructed a series of simplified simulation scenarios using an agent-based model calibrated to entomological, epidemiological, and genomic data from this cohort study to investigate whether the lack of spatial structure observed in the cohort could be due to inherent power limitations of this analytical method. We further investigated how our hypothesis testing behaves under different sampling schemes, levels and mechanisms of missingness, transmission intensity, and patterns of human mobility. In high transmission settings, we found that identity-by-state measures of relatedness, even using frequently sampled, longitudinal infection data were likely underpowered to detect moderate levels of spatial structure in parasite populations. This has important implications for the use of parasite genomic data in illuminating patterns of transmission in areas of high endemicity.

AMPLICON DEEP SEQUENCING REVEALS MULTIPLE GENETIC EVENTS LEAD TO TREATMENT FAILURE WITH ATOVAQUONE-PROGUANIL IN PLASMODIUM FALCIPARUM

Daniel Castañeda-Mogollón, Noah B. Toppings, Claire Kamaliddin, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

Atovaquone-Proguanil (AP) is used as treatment for uncomplicated malaria, and as a chemoprophylactic agent against Plasmodium falciparum. Imported malaria remains one of the top causes of fever in Canadian returning travellers. In this study, twelve sequential whole-blood samples before and after AP treatment failure were isolated from a patient diagnosed with P. falciparum malaria upon their return from Uganda and Sudan after partial compliance with AP as a chemoprophylactic agent. Targeted ultra-deep sequencing was performed on the cytb, dhfr, and dhps markers of treatment resistance before and during the episode of recrudescence. Haplotyping profiles were generated using three different approaches: msp2-3D7 agarose and capillary electrophoresis, and cpmp using amplicon deep sequencing (ADS). A complexity of infection (COI) analysis and haplotyping profiles were included. De-novo cytb Y268C mutants were observed during an episode of recrudescence 17 days and 16 hours after the initial malaria diagnosis and AP treatment, indicating treatment failure. No Y268C mutant reads were observed in any of the samples prior to the recrudescence,, suggesting no preselected mutants within the limits of detection of electrophoresis and ADS haplotyping. SNPs in the dhfr and dhps genes were observed upon initial presentation. The haplotyping profiles suggest multiple clones mutating under AP selection pressure (COI>3) with a soft selective sweep. Significant differences in COI were observed by capillary electrophoresis and ADS compared to the agarose gel results. ADS using cpmp revealed the lowest haplotype variation across the longitudinal analysis compared to the msp2 length-polymorphic marker. Our findings highlight the power of ultra-deep sequencing to provide a higher resolution to reveal the natural selection of a mutation as well as haplotyping profiles to understand P. falciparum infection dynamics. Longitudinal samples should be analyzed in haplotyping studies to increase the precision, sensitivity, and specificity in haplotyping calls. This is the first study to report multiclonal (COI>3) cytb de novo mutation.

A CANDIDATE GENE ANALYSIS OF SEVERE MALARIA VARIANTS IN A COHORT OF MALIAN CHILDREN IDENTIFIES A NOVEL SUSCEPTIBILITY LOCUS IN CSMD1 GENE

Delesa Damena Mulisa[1], Amadou Barry[2], Robert Morrison[3], Santara Gaoussou[2], Almahamoudou Mahamar[2], Oumar Attaher[2], Alassane Dicko[2], Patrick Duffy[3], Michal Fried[1]

[1]Molecular Pathogenesis and Biomarkers Section, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Sciences Techniques and Technologies of Bamako, P.O Box 1805, Bamako, Mali, [3]Molecular Pathogenesis and Immunity Section, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Plasmodium falciparum malaria is still a leading cause of child mortality in sub-Saharan Africa. Malaria infection can be asymptomatic or symptomatic, with sequelae ranging from no clinical signs to severe disease. Variations in malaria clinical outcomes are partly attributed to host genetic factors with estimated narrow-sense heritability of 23%. Here, we investigated associations of human candidate gene polymorphisms and risk of severe malaria (SM) in a cohort of Malian children. Based on our previous Genome-wide Association (GWAS) analysis, specific candidate genes (N=11) were selected for in-depth analysis. Selection criteria included gene-level GWAS scores, functional overlap with malaria pathogenesis, and evidence of association with protection or susceptibility to other infectious and inflammatory diseases. Twenty-two representative single nucleotide polymorphisms (SNPs) residing within these genes were selected primarily based on p-values in our previous GWAS studies as well as allele frequency in West African populations. The selected SNPs were genotyped using KASP technology in 477 DNA samples (87 children that had experienced SM and 390 that did not). Logistic regression analysis revealed that a common intron variant, rs13340578 in Cub and Sushi Multi Domain (CSMD1) gene, is associated with increased susceptibility to severe malaria in a recessive mode of inheritance (MAF = 0.42, OR=1.8, 95% CI = [1.78, 1.84], P= 0.029). The SNP is in linkage disequilibrium (LD) (r2=0.75) with a regulatory variant, rs59961277, located 888bp up-stream in the complement control (Sushi) domain of CSMD1. This finding suggests that modified regulation of complement may contribute to malaria disease severity. Further studies are needed to identify causal variants in this locus and the underpinning molecular mechanisms mediating SM.

5453

PROTECTIVE HUMORAL RESPONSE TO PLASMODIUM FALCIPARUM PF27 AND ITS ORTHOLOG P. VIVAX PV27 ANTIGENS IN SERA FROM DANGASSA AND KOILA, TWO MALARIA ENDEMIC AREAS IN MALI

Salimata Kante[1], Saidou Balam[1], Drissa Konate[1], Merepen dite Agnes Guindo[1], Abdouramane Traore[1], Karamoko Tangara[1], Issoufi Y Maiga[1], Seidina AS Diakite[1], Fatoumata Kasse[1], Karim Traore[1], Larissa Denou[1], Seydou Doumbia[1], Corradin Giampietro[2], Mahamadou Diakite[1]

[1]USTTB, BAMAKO, Mali, [2]University of Lausanne, Lausanne, Switzerland

We identified new Plasmodium falciparum (Pf) and P. vivax (Pv) proteins using Bioinformatic tools. Preliminary results showed that individuals sera from Malian donors reacted well with the couple Pf27/Pv27 antigens (42.7% vs 29.2%) about antigens tested, suggesting existence of crossreactivity between Pf and its ortholog Pv proteins and their potential as malaria vaccine candidates. This study aimed to assess the protective immunity (antibody responses) associated with Pf27/Pv27 proteins in sera from a cohort study in Mali. Samples and data on malaria episodes were collected during cross-sectional survey in December 2021 amongst 209 participants from Dangassa and Koila, two malaria endemic areas located approximately at 82 km south-west and 385 km northeast of Bamako, the capital city of Mali, respectively. Antigenic peptides covering orthologs Pf and Pv protein were tested on sera using ELISA assay. Overall prevalence of antibodies anti-Pf27 vs Pv27 was 55.9% vs 64,7% in Dangassa and 54.2% vs 63.6% in Koila. In Dangassa, Pf27 seroprevalence (87.5% vs 42.4%, p = 0.02) and antibody levels (p = 0.010) were significantly higher in children healthy during malaria transmission season, while they were similar in adults. No significant variation in antibody levels against both proteins was observed in Koila. High level of antibodies against Pf27 in children and its association with protection against clinical malaria in Dangassa may warrant further investigation of Pf27 as a potential malaria vaccine candidate.

5454

BROADLY REACTIVE ANTIBODIES TARGET SEVERE MALARIAL ANTIGEN TO NEUTRALISE PARASITE SEQUESTRATION

Sai Sundar Rajan Raghavan[1], Louise Turner[1], Gregory Martin[2], Andrew Ward[2], Evelien Bunnik[3], Thomas Lavstsen[1]

[1]Centre for Medical Parasitology, Copenhagen, Denmark, [2]The Scripps Research Institute, San Diego, CA, United States, [3]The University of Texas Health Science Center, San Antonio, TX, United States

Severe childhood malaria caused by Plasmodium falciparum is associated with the accumulation of parasite-infected erythrocytes in blood vessels and tissues. Plasmodium falciparum erythrocyte membrane protein 1 (PfEMP1) family expressed on the surface of infected erythrocyte binds to the endothelial protein C receptor (EPCR), is associated with development of severe symptoms. Naturally acquired antibodies which block this interaction are found in people from malaria endemic regions and are expected to confer protection to severe malaria. Individuals developing protein against severe malaria harbour broadly reactive antibodies against EPCR binding PfEMP1s. In this study, through the characterisation of PfEMP1 specific B cell receptor and serum repertoire, we have isolated antibodies capable of neutralising PfEMP1 - EPCR interaction. The structural and sequence analyses have revealed unique epitopes of these antibodies capable of recognising high sequence diverse PfEMP1s and neutralise EPCR interaction.

5455

THE CHEMOKINE RECEPTOR CXCR3 PLAYS A CRITICAL ROLE IN T CELL-MEDIATED PROTECTION FROM LIVER-STAGE PLASMODIUM INFECTION

Rebecca Blyn[1], Laura M. Reynolds[2], Lisa Wegmair[3], Patrick Lewis[2], Amina Sheikh[4], Vera Okolo[2], Brandon Wilder[5], Stefan Kappe[2], Nana Minkah[2]

[1]University of Washington, Seattle, WA, United States, [2]Seattle Children's Research Institute, Seattle, WA, United States, [3]AstraZeneca, Hamburg, Germany, [4]NYIT College of Osteopathic Medicine, Glen Head, NY, United States, [5]Oregon Health and Sciences University, Portland, OR, United States

Plasmodium infection involves an asymptomatic liver stage that occurs in hepatocytes and a symptomatic blood stage that occurs in red blood cells. Immunization with whole sporozoite vaccines including genetically attenuated parasites (GAPs) that arrest in the liver can completely prevent the symptomatic blood stage. However, improving these GAPs requires a better understanding of anti-Plasmodium hepatic immunity. Activated T cells increase surface expression of CXCR3 and CXCR3+ liver-resident memory CD8 T cells (TRMs) are critical mediators of protection against infection following GAP vaccination. Hepatocytes also upregulate the CXCR3-binding chemokines CXCL9 and CXCL10 during liver-stage Plasmodium infection, indicating a role for CXCR3 in T cell-mediated protection. We find that GAP-immunized CXCR3-/- mice exhibit impaired ability to control liver-stage infection at 40 days post-immunization. While flow cytometry analysis shows impaired recruitment of activated CD8 T cells into the livers of CXCR3-/- mice early after GAP immunization, by day 40 GAP-immunized CXCR3-/- and wildtype mice exhibit similar numbers of TRMs. This indicates that while CXCR3 is critical early after immunization, other factors may recruit T cells to the liver at later timepoints. However, given that CXCR3-/- mice have impaired protection from challenge at 40 days post-immunization, CXCR3 must play other roles in TRM reactivation, recruitment, and/or function. Hepatic immunity is unique in that hepatocytes and resident immune cells are asymmetrically positioned across the tissue. Recent studies indicate that parasite development in the liver is not uniformly distributed. Thus, we hypothesize that CXCR3 modulates TRM positioning in the liver such that these cells are optimally placed to respond to future infections. Ongoing spatiotemporal studies will characterize parasite development, chemokine production, and TRM positioning to determine how chemokines impact GAP-induced immunity. These findings about the role of CXCR3 in T cell-mediated protection from liver-stage Plasmodium could assist in the development of improved GAP vaccines.

Malaria is a life-threatening disease caused by Plasmodium parasites and transmitted via infected Anopheles mosquitoes. In 2021, an estimated 247 million cases and 619,000 deaths were registered worldwide, with Sub-Saharan Africa bearing the major burden. Clinical manifestations of malaria can vary and depend on a dynamic interplay between host, parasite, and environmental factors. Distinct "malaria phenotypes" can be categorized as asymptomatic, uncomplicated, or severe. The course of the infection is shaped by the host immune response. Within the adaptive immune system, Plasmodium-specific T and B cells play a crucial role in determining the progression from asymptomatic to severe malaria and the development of immunological memory. However, the dynamics and interactions between distinct immune populations in response to malaria remain poorly understood. To define the immunoprofile driving individual reactions, a heterogeneous population with a full spectrum of clinical phenotypes needs to be interrogated. To this purpose, we designed a longitudinal cohort study involving 300 individuals aged 5 to 65 years old from a highly malaria-endemic area of western Kenya. Our baseline surveys indicated a prevalence by RDT of 40.7% and the presence of both symptomatic and asymptomatic cases. 46.3% of these showed repeated infection at the following monthly visit. By analyzing field-transmission samples throughout a broad range of age groups, we aim to profile antimalarial immunity and stratify the cohort into distinct infection groups. Moreover, while cross-sectional studies do not allow to distinguish between asymptomatic or pre-symptomatic states, in longitudinal cohorts disease progression is tracked overtime, allowing asymptomatic cases to be defined more clearly and individuals categorized into a gradient of clinical phenotypes. By analyzing peripheral blood mononuclear cells (PBMCs) from the cohort via high-throughput mass cytometry (CyTOF), we will gain insights into distinct immunological signatures of the host antimalarial response, eventually leading to new vaccination and immunotherapeutic strategies.

The pathogenicity of severe malaria (SM) caused by Plasmodium falciparum is supported by the adhesion of P. falciparum-infected erythrocytes (IEs) to the microvasculature of infected individuals. This adhesion is mediated

by PfEMP-1, which binds one of the most common receptors of the human host, intracellular adhesion molecule-1 (ICAM-1). Knowledge on the quantity and quality of IgG to such PfEMP-1 is limited. The acquisition of IgG specific for IEs, selected for expressing ICAM-1 binding PfEMP-1 and the IgG-mediated opsonic-phagocytosis of such IEs are unknown and the objective of this study was to provide such data.Plasma samples collected from Beninese children under the age of five years with either SM or uncomplicated malaria (UM) were used to measure antibody levels to two recombinant PfEMP-1 domains and their corresponding native proteins expressed on the surface of IEs. ELISA was used to measure PfEMP-1-specific antibodies to the domains, flow cytometric based assay was employed for IE surface reactivity and antibody-mediated opsonic phagocytosis to measure the functional properties of antibodies with respect to the selected PfEMP-1 expressing IEs.Levels of PfEMP-1-specific IgG to the domains and their corresponding IEs were similar in the two groups, SM and UM, suggesting similar exposure to P. falciparum parasites expressing those PfEMP-1 variants. Also, no differences in the reactivity to native IT4VAR13 were observed between all plasma at hospitalization and at convalescence. However, in qualitative assessment, the ability of antibodies to promote opsonic phagocytosis of IEs by monocytes (THP-1 cells) was significantly higher in children with UM at hospitalization on PFD1235w expressing parasite. The findings indicate similar P. falciparum malaria exposure in children with either SM or UM and supports the presence of antibody dependent phagocytosis as a measure of antibody effector function and its association with protection against SM in children.

Gut microbiota composition is known to alter the susceptibility of mice to Plasmodium infection; however, the impact of gut microbiota on the severity of malaria in humans is less well defined. We collected stool samples from a cohort of 180 Malian children aged six to ten years at multiple time points before, during, and after a Plasmodium transmission season, analyzed them using 16S rRNA gene sequencing, and examined the relationship between fecal microbiota composition and the prospective susceptibility of the children to symptomatic Plasmodium infection. We found that microbiota composition of the pre-transmission season sample from ten-year-old children was significantly associated with whether the children were resistant or susceptible to the development of malaria during the study period. No relationship was observed in younger children, who overwhelmingly developed febrile symptoms when infected, or in samples taken during or shortly after the transmission season, possibly due to obfuscation by additional season-dependent factors. In order to examine the potential causal role of gut microbiota, germ-free mice were colonized with the fecal samples from either resistant or susceptible children and then infected with Plasmodium. Mice that received fecal samples from resistant children displayed significantly better control of their parasitemia compared to mice that received fecal samples from susceptible children, demonstrating that gut microbiota play a causal role in malaria severity in Malian children. The specific mechanisms and bacteria associated with susceptibility to malaria are currently being investigated.

[1]Stanford University, Palo Alto, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Makerere University School of Medicine, Kampala, Uganda, [4]Uganda Christian University, Mukono, Uganda, [5]University of California, San Francisco, San Francisco, CA, United States

In recent years, the ability of natural killer (NK) cells to mediate antimalarial immunity through antibody-dependent cellular cytotoxicity (ADCC) has become increasingly appreciated. Our group recently reported that an atypical population of NK cells prevalent in malaria-exposed children has enhanced ADCC activity against opsonized infected erythrocytes superior to that of conventional NK cells. However, ADCC was only evaluated in wild-type erythrocytes infected with laboratory-adapted P. falciparum, despite the high prevalence of hemoglobin polymorphisms in endemic areas and antigenic diversity of field isolates. Furthermore, extensive cellular phenotyping to find features associated with enhanced cytotoxicity and malaria exposure have not been conducted. This work aims to characterize the impact of parasite diversity, erythrocyte polymorphism, NK cell phenotypes, and malaria exposure on the ability to mediate ADCC against infected erythrocytes. We have already found that HbAS erythrocytes and plasma from high-transmission areas enhance ADCC in comparison to HbAA erythrocytes and low-transmission plasma. Experiments in progress are characterizing NK cell phenotypic traits associated with ADCC capacity in malaria-exposed Ugandans in comparison to malaria-naive North Americans. Peripheral blood mononuclear cell (PBMC) samples from the PRISM (Program for Resistance, Immunology, Surveillance, and Modelling of Malaria) observational study cohort in Nagongera, Uganda and malaria-naive North Americans are stimulated with infected erythrocytes or pro-inflammatory cytokines analyzed for phenotypic markers and activation using multiparameter flow cytometry. Killing of infected erythrocytes by NK cells is assessed using a colorimetric assay that quantifies released hemoglobin in cell supernatant. These results will help improve the translatability of future research by creating experimental conditions that better reflect malaria-endemic settings.

BIOCHEMICAL AND BIOINFORMATIC CHARACTERIZATION OF SURFACE EXPRESSED HYPERVARIABLE PROTEIN FAMILIES (RIFIN AND STEVOR) ASSOCIATED WITH PATHOGENESIS AND ACQUIRED IMMUNITY TO PLASMODIUM FALCIPARUM INFECTION

Hristina Vasileva

London School of Hygiene and Tropical Medicine, London, United Kingdom

Malaria, caused by the infectious parasite Plasmodium falciparum (Pf), is a vector borne disease, responsible for approximately 619 thousand deaths and 247 million cases worldwide in 2021, with 94% cases in sub-Saharan Africa. Pathogenesis of malaria infection is dependent on parasite and host factors, and geographic and social factors, causing different clinical outcome and disease severity. Parasite virulence is partly caused by evasion of the human host immune system during the blood stage of infection. Sequestration and cytoadherence are characteristic Pf virulence factors, enabled by parasite-derived proteins expressed on the surface of infected erythrocytes (IEs). These proteins are antigenic and are associated with acquired immunity to Pf. IE surface-expressed antigens are associated with antigenic variability, called Variant Surface Antigens (VSA). VSA are

translocated from blood stage Pf to the IE surface via protein trafficking through Maurer's cleft, a parasite-derived membranous structure, and are expressed on the IE membrane. RIFIN and STEVOR are VSA protein families encoded respectively by 180 rif and 40 stevor gene copies per parasite. Members of each family differ mostly in their hypervariable region, exposed to the circulation and possessing antigenic epitopes. Both variable domains are associated with Pf exposure and potentially clinical outcome. Seroreactivity and recognition to both protein families are age and exposure dependent, with higher reactivity in adults and higher domain recognition in individuals with clinical malaria than in subpatent infections. This study is the first to successfully express isolated domains of RIFIN and STEVOR proteins as recombinants, characterize their antigenicity, expand understanding of the Pf proteome, by investigating novel markers for exposure to Pf and develop a library of variants to explore the breath of antibody responses in participants following mass drug administrations (MDA) in clinical trials (MATAMAL NCT04844905; MASSIV NCT03576313) to explore the impact of the trial interventions on naturally acquired immunity to Pf.

CRYO-EM REVEALS THE STRUCTURAL BASIS OF EPITOPE SELECTIVITY AND PROTECTION FROM MALARIA INFECTION IN A FAMILY OF POTENT ANTI-PFCSP ANTIBODIES

Gregory Martin[1], Jon Torres[1], Tossapol Pholcharee[2], Monica Fernandez Quintero[3], Wen-Hsin Lee[1], Yevel Flores-Garcia[4], Daniel Emerling[5], Randall MacGill[6], Emily Locke[6], C. Richter King[6], Ashley Birkett[6], Fidel Zavala[4], Ian Wilson[1], Andrew Ward[1]

[1]The Scripps Research Institute, San Diego, CA, United States, [2]Oxford University, Oxford, United Kingdom, [3]The University of Innsbruck, Innsbruck, Austria, [4]Johns Hopkins University, Baltimore, MD, United States, [5]Atreca Inc, San Carlos, CA, United States, [6]PATH's Center for Vaccine Innovation and Access, Washington, DC, United States

The generation of high-quality antibody responses to PfCSP, the primary surface antigen of Plasmodium falciparum sporozoites, is paramount to the development of an effective malaria vaccine. Here we present an in-depth structural and functional analysis of a panel of potent antibodies targeting the PfCSP major repeat region (NPNA) and the highly potent mAb L9, which targets the PfCSP minor repeats (NPNV). Each of these mAbs is encoded by the IGHV3-33 heavy chain germline gene, which belongs to one of the most prevalent and potent antibody families induced in the anti-CSP immune response in humans. Cryo-EM reveals a remarkable spectrum of higher-order Fab-CSP structures stabilized by homotypic interactions, many of which correlate with somatic hypermutation. Notably, the homotypic interface in the L9-CSP complex is distinct from the panel of NPNA-specific mAbs; this is the first observation of homotypic interactions in a PfCSP epitope outside of the NPNA region. In vitro and in vivo data demonstrate the key role of these mutated homotypic contacts for high PfCSP avidity and in protection from P. falciparum malaria infection. Importantly, correlation analyses of mAb binding kinetics with in vivo protective efficacy indicates high PfCSP affinity is insufficient to confer potency, highlighting a potential structural determinant of protection. Overall, these data emphasize the importance of anti-homotypic affinity maturation in the frequent selection of IGHV3-33 antibodies and inform next-generation PfCSP vaccine design.

ANTIBODY PROFILES AGAINST NON-MALARIA PATHOGENS DISPLAYED IN PLASMODIUM VIVAX-INFECTED INDIVIDUALS FROM THE PERUVIAN AMAZON

Elizabeth Melisa Villasis[1], Fiona Angrissano[2], Mitchel Guzman[1], Julian Torres[1], Katherine Garro[1], Stefano Garcia[1], Caroline Abanto[1], Luis Cabrera[1], Herbert Opi[2], James Beeson[2], Joseph Vinetz[3], Dionicia Gamboa[1], Leanne Robinson[2], Katherine Torres[1]

[1]Universidad Peruana Cayetano Heredia, LIMA, Peru, [2]Burnet Institute, Melbourne, Australia, [3]Yale University, New Haven, CT, United States

In this study, we screened IgG antibody responses to serological markers (seromarkers) from malaria and other non-malaria pathogens endemic in tropical areas, in Plasmodium vivax (Pv)-infected individuals from the Peruvian Amazon. Between 2018 - 2021, a nested case-control study was conducted in the Peruvian Amazon, for a comparison of immune responses between Asymptomatic (Asym, n=28) and Symptomatic (Sym, n=30) Pv-infected individuals vs control endemic individuals (n=30). Asym individuals had no common malaria symptoms but remained infected with Pv during a 3-week follow-up (qPCR). Control endemic individuals had no history related to malaria during the last three years and no history of comorbidities or chronic infections. Serum samples from all individuals were processed to measure exposure (IgG antibodies responses) against 24 antigens from a validated panel of seromarkers for neglected tropical diseases, using Multiplex Bead Assay (Luminex).Results: Pv-infected individuals showed significantly high IgG antibody responses against PvMSP119 protein and seromarkers for Chikungunya and Filariasis ($p < 0.0001$); Strongyloidiasis, Taeniasis, and Neurocysticercosis ($p \leq 0.01$); and Giardiasis and Trachoma diseases ($p < 0.05$) compared to endemic controls. Interestingly, IgG antibody levels against seromarkers for DENGUE serotype 1, 2, 3, and 4 were lower than endemic controls ($p < 0.0001$). No significant difference was found for IgG responses between Asym and Sym Pv-infected individuals. Furthermore, using a classical cut-off, we were able to determine a higher proportion of Pv-infected individuals exposed to Chikungunya (98% vs 67%), Filariasis (76 vs 37%), Strongyloidiasis (69% vs 30%), Neurocysticercosis (66% vs 23%), and Taeniasis (47% vs 17%) in comparison to endemic controls respectively. In conclusion, his study demonstrates that Pv-infected individuals in the Peruvian Amazon are more exposed to other tropical infectious diseases than endemic control individuals.

PLACENTAL MALARIA MODULATES NEONATAL DENDRITIC CELLS' PHENOTYPE AND FUNCTION: A CROSS SECTIONAL STUDY IN BENIN

Sebastien Dechavanne[1], Omar Malade[2], Simon Akpi[2], Nadine Fievet[3], Achille Massougbodji[2], Elodie Segura[4], Celia Dechavanne[1]

[1]IRD MERIT, Benin Clinical Research Institut, Calavi, Benin, [2]Benin Clinical Research Institut, Calavi, Benin, [3]IRD MERIT, Paris, France, [4]Curie Institut, INSERM U932, Paris, France

Malaria in Pregnancy (MiP) is characterized by the accumulation of Plasmodium falciparum (Pf)-infected red blood cells in the placenta and leads to adverse outcomes in infant. They have a shorter delay to first malaria infection and a higher number of malaria and non-malaria infections in infancy. This indicates that not only infant's adaptive but also innate immunity is modulated by maternal infection. Several studies demonstrated that immune responses were modulated at birth depending on the timing of infection during pregnancy (recent-active, chronic-active or past MiP). There are strong in vitro and ex vivo evidences that Pf is also able to modulate Dendritic Cells (DCs). In that sense, our team showed that neonatal DCs are partially activated in case of MiP. The mechanisms responsible for this modulation and the capability of those DCs to induce (or not) a strong T cell response have not been established. In our cross sectional study, we have purified DCs from cord bloods of 50 naturally-exposed individuals and phenotyped the DC subtypes (cDC1, cDC2 and pDC). We confirmed the partial activation of neonatal DCs with a lower expression of CD80 in

cDC2 when the mothers are Pf-infected (2.77 [CI:2.01; 3.13]) compare to not infected (3.25 [CI:2.56;5.55], p=0.05). Then, we have explored the functionality of neonatal DCs by ex vivo stimulation and co-culture with naïve and hyper-immune T cells (from healthy donors). Compare to chronic MiP, DCs from neonates born from mother with active MiP induced a lower T cell proliferation (1.28 [sd:0.65] vs 1.66 [sd:0.54], p=0.02), a lower Th2 frequency (3.78 [sd:8.38] vs 4.27 [sd:2.64], p=0.005) and a higher Treg frequency (11.53 [sd:9.0] vs 3.98 [sd:6.3]). In parallel, we have characterized the T cells from those same neonates. We observed a high level and frequency of CD28 in newborns' CD4+CXCR3+ and CD8+CXCR3+ T cells in case of active MiP, suggesting that neonatal T cells are fully capable of being activated. Overall, our results demonstrate that the modulation of neonatal DCs differs depending on the timing of infection during pregnancy and may impact the efficacy of the crosstalk between the DCs and the T cells.

5464

THE ROLE OF PFEMP1 IN SICKLE-CELL RESISTANCE TO PLASMODIUM FALCIPARUM MALARIA

Zakaria Seidu[1], Andrew Oleinikov[2], Helena Lamptey[1], Morten Pontoppidan[3], Michael F. Ofori[1], **Lars Hviid**[3], Mary Lopez-Perez[3]

[1]University of Ghana, Accra, Ghana, [2]Florida Atlantic University, Boca Raton, FL, United States, [3]University of Copenhagen, Copenhagen, Denmark

Heterologous carriers (HbAS) of the sickle-cell mutation (HbS) enjoy clinical protection from severe Plasmodium falciparum malaria relative to individuals with either normal hemoglobin (HbAA) or homozygous mutation (HbSS; sickle-cell disease). However, all three genotypes are equally susceptible to infection with these parasites. The reason for the clinical resistance to severe malaria in HbAS is not fully understood. The ability of P. falciparum-infected erythrocytes (IEs) to adhere to host vascular receptors is a central component of the pathogenesis of the disease in general, and of severe malaria in particular. This adhesion is mediated by PfEMP1, parasite-encoded adhesins displayed on the IE surface on characteristic structures called knobs. It is well-documented that knob formation is compromised in HbAS, and it is therefore often assumed that the clinical resistance against severe malaria in HbAS is a consequence of impaired adhesion and increased splenic destruction of IEs. However, little direct evidence is available. An alternative - or additional - possibility is that parasites in HbAS IEs are able to modulate the expression of PfEMP1 variants associated with severe malaria. We studied the expression of PfEMP1 by parasites grown in vitro in HbAA and HbAS erythrocytes under different oxygen tensions. We also assessed the immune response to PfEMP1 variants associated with uncomplicated and severe malaria in Ghanaian children with and without sickle-cell trait. Finally, we determined the proportion of circulating and sequestered IEs in these children. Our results provide direct evidence of impaired cytoadhesion of HbAS IEs in vivo, whereas we did not find convincing in vitro or serological evidence in favor of the hypothesis that resistance to severe malaria in children with sickle-cell trait reflects a qualitative modulation of PfEMP1 expression on HbAS IEs.

5465

ASSESSMENT OF HOST CLINICAL PARAMETERS AND PARASITE DETERMINANTS RESPONSIBLE FOR DISEASE SEVERITY

Aditi Arya[1], Shyam Sundar Meena[2], Monika Matlani[3], Vineeta Singh[4]

[1]ICMR-National Institute of Malaria Research, New Delhi India, India, [2]Department of Pediatrics VMMC, Safdarjung Hospital, New Delhi, India, [3]Department of Microbiology, VMMC, Safdarjung Hospital, New Delhi, India, [4]ICMR-National Institute of Malaria Research, New Delhi, India

Plasmodium falciparum is known to cause severe malaria but since the last decade, P. vivax is also seen to be causing severe malaria in clinical isolates. There are no reported studies for P.vivax immunopathogenesis in clinical patients. In the present study clinical parameters, cytokine profile (SOD-1, TNF-α, IL-10, IL-6, and IFN-γ), integrin gene, and parasite molecular marker (vir genes, drug resistance genes, and msp3 genes) were analyzed in P.vivax clinical infections. A total of 169 P. vivax samples were collected and categorized into severe vivax malaria (n=106) and non-severe vivax malaria (n=63) according to WHO severity criteria. Samples were diagnosed with microscopy, RMAT, and 18S PCR. We measured host biomarker levels of interferon (IFN-γ), superoxide dismutase (SOD-1), interleukins viz. (IL-6, IL-10), and tumor necrosis factor (TNF-α) in patient plasma samples by ELISA for pro- and anti-inflammatory cytokines in severe malaria. Severity was assessed and correlated with the integrin, drug resistance, Pvmsp3, and vir gene using PCR, RT-PCR and sequencing analysis. In our study, thrombocytopenia and anemia were major symptoms in severe P. vivax patients. The levels of cytokines (IL-10, IL-6, and TNF-α) and the anti-oxidant enzyme SOD-1 were significantly higher in severe vivax patients. Molecular genotyping of Pvmsp3α gene has four major genotypes out of which Type B (1.5kb) was predominant in severe and Type C (2kb) was predominant in non-severe samples. For drug resistance genes severe isolates had more mutation than non-severe isolates. Vir-14 gene indicates a significantly higher expression level in the severe samples and Vir-10 related gene showed a higher level of expression in non-severe vivax samples. In conclusion, higher levels of inflammatory cytokine can serve as baseline data for evaluating severe P. vivax infections which will be helpful in developing an effective diagnostic biomarker for understanding the immunopathology of P. vivax malaria.

5466

THE DIRECT BINDING OF PLASMODIUM VIVAX AMA1 TO ERYTHROCYTES DEFINES A RON2-INDEPENDENT INVASION PATHWAY

Seong-Kyun Lee[1], Leanne Low[1], John Anderssen[1], Lee Yeoh[2], Paola Carolina Valenzuela Leon[1], Damien Drew[2], Johannes Doehl[1], Eric Calvo[1], Louis Miller[1], James Beeson[2], Karthigayan Gunalan[1]

[1]NIAID/NIH, Rockville, MD, United States, [2]Burnet Institute, Melbourne, Australia

Plasmodium vivax is a major human malaria species and is the most geographically widespread disease accounting for approximately 2.5 billion people living under threat of infection. Nonetheless, the study of P. vivax has been greatly impeded due to the absence of an in vitro cultivation system, with only two host proteins, Duffy blood group antigen and Transferrin receptor 1, identified as binding partners for P. vivax Duffy Binding Protein (PvDBP) and Reticulocyte Binding Protein 2b (PvRBP2b), respectively. The increase, thus, in Duffy-negative infections and lack of P. vivax-specific vaccine candidates make the discovery of more ligand/receptor combinations an important task. In this study, we used a transgenic parasite in which Plasmodium falciparum parasites were genetically modified to express P. vivax apical membrane antigen 1 (PvAMA1) protein in place of PfAMA1 to study PvAMA1-mediated invasion. In P. falciparum, AMA1 interaction with rhoptry neck protein 2 (RON2) is known to be crucial for invasion, and PfRON2 peptides (PfRON2p) blocked the invasion of PfAMA1 wild-type parasites. However, PfRON2p has no effect on the invasion of transgenic parasites expressing PvAMA1 indicating that PfRON2 had no role in the invasion of PvAMA1 transgenic parasites. Interestingly, PvRON2p blocked the invasion of PvAMA1 transgenic parasites in a dose-dependent manner. We found that recombinant PvAMA1 domains 1 and 2 (rPvAMA1) bound to reticulocytes and normocytes indicating that PvAMA1 directly interacts with erythrocytes during the invasion, and invasion blocking of PvRON2p may result from it interfering with PvAMA1 binding to erythrocytes. It was previously shown that the peptide containing Loop1a of PvAMA1 (PvAMA1 Loop1a) is also bound to reticulocytes. We found that the Loop1a peptide blocked the binding of PvAMA1 to erythrocytes. PvAMA1 Loop1a has no polymorphisms in contrast to other PvAMA1 loops and may be an attractive vaccine target. We thus present the evidence that PvAMA1 binds to erythrocytes in addition to interacting with PvRON2 suggesting that the P. vivax merozoites may exploit complex pathways during the invasion process.

5467

ELEVATED FERRITIN, SEVERE MALARIA, AND ACUTE KIDNEY INJURY

Kazinga Caroline[1], Ivan Mufumba[1], Ruth Namazzi[2], Anthony Batte[2], Robert Opoka Opika[3], Chandy John[4], Andrea Conroy[5]

[1]CHILD Biomedical Research Laboratory, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]Aga Khan University, Nairobi, Kenya, [4]Indiana school of medicine, Indianapolis, IN, United States, [5]Indiana School of Medicine, Indianapolis, IN, United States

Ferritin is a multimeric iron-storage protein expressed by different tissues to either efficiently bind and sequester iron (spleen and liver) or respond to free iron associated oxidative stress (kidney). Ferritin levels are increased in severe malaria but the clinical implication and importance of this pathway in severe malaria pathogenesis is poorly understood. Children <5 years of age with severe malaria (n=594) and community children (n=120) were enrolled at two sites in Uganda and followed for one year. Ferritin was measured at enrolment in all children and one month follow-up in severe malaria survivors. A ferritin threshold of ≥ 5000ng/mL was considered elevated. At enrolment, 22.4% of children with severe malaria had elevated ferritin levels and clinical risk for elevated ferritin included acute kidney injury and signs of hemolysis (severe anemia, jaundice, blackwater fever). Elevated ferritin was associated with increased mortality with 11.3% of children with elevated ferritin dying compared to 6.1% of children with normal ferritin levels (p=0.04). However, ferritin was no longer related to mortality when adjusted for acute kidney injury. At one month follow-up, none of the severe malaria survivors had elevated ferritin but the median ferritin levels remained higher compared to community children (p<0.0001). The presence of elevated ferritin on admission was associated with increased post-discharge mortality OR 3.32 (95% CI 1.89 to 5.81), p<0.0001 independent of acute kidney injury or persistent kidney disease. We further explored the relationship between elevated ferritin and pathways of host response on admission. Elevated ferritin was strongly associated with increases in markers of hemolysis and depleted heme-hemoglobin scavengers (p<0.001 for all) but was not associated with the acute phase response. These findings suggest that ferritin increases in the context of acute kidney injury in response to free iron from hemolysis. Further, ferritin may be a useful biomarker to identify children with severe malaria who have higher risk of post discharge mortality.

5468

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON MALARIA PREVALENCE AND IMMUNITY AMONG CHILDREN IN NORTHERN BENIN

Azizath Moussiliou[1], Charles Ahouansou[1], Blaise Choki[1], Achille Massougbodji[2], Adrian Luty[3], Thierry Adoukonou[1], Nicaise Georges Tuikue Ndam[3]

[1]ENATSE (Ecole Nationale des Techniciens en Santé publique et Surveillance Epidémiologique) Université de Parakou, Parakou, Benin, [2]Institut de Recherche Clinique du Bénin, Abomey-Calavi, Benin, [3]Université de Paris Cité, MERIT, IRD, Paris, France

Malaria is still a major cause of morbidity and mortality despite all efforts to control the disease. The burden of death is still particularly marked in young children in sub-Saharan Africa. A new preventive strategy was recently developed to strengthen the fight against pediatric malaria in areas of seasonal transmission called Seasonal Malaria Chemoprevention (SMC). The Ministry of Health in Benin, as in other countries with this epidemiological facies, initiated the implementation of this strategy in 2019. However, and as often, the countries have not provided the means to assess the impact of this program. This study aims to evaluate the effects of SMC with Sulfadoxine-Pyrimethamine (SP) and Amodiaquine (AQ) on malaria incidence and consequence as well as on the acquisition and maintenance of anti-malarial immunity in treated children. We conducted a cross-sectional study on children aged 6 to 59 months living in two villages in northern Benin, subjected or not to SMC. Sociodemographic and clinical data as well as repeated blood samples were collected from 440 children (before, during and after SMC treatment). Samples were analyzed for malaria infections by RDT, microscopy and PCR. Anti-malaria immunity was assessed to investigate the repertoire of antibody responses to critical antigens using a panel of 28 antigens targeting PfEMP1, GLURP and MSP1 by Luminex assay.Despite the implementation of the SMC, the prevalence of malaria remained similar in treated and untreated villages. During the follow up, malaria prevalence by PCR rather increased during SMC in both villages and decreased, after the SMC in the treated village. No significant impact of SMC was observed on the dynamics and level of antibodies against PfEMP1 and other malaria antigens suggesting that in an area of high seasonal malaria transmission, SMC implementation do not impact acquisition and maintenance of anti-malaria immunity.

5469

NEUREGULIN 1 DECREASES HEME-INDUCED INFLAMMATION IN INDUCED PLURIPOTENT STEM CELLS-DERIVED ENDOTHELIAL CELLS FROM CHILDREN WITH INTRAVASCULAR HEMOLYSIS

Cecilia Elorm Lekpor[1], Adriana Harbuzariu[2], Andrew A. Adjei[1], Afua Darkwah Abrahams[1], Felix A. Botchway[3], Michael D. Wilson[1], Kwadwo A. Kusi[1], Godfred Futagbi[1], Wesley Solomon[4], Jonathan K. Stiles[4]

[1]University of Ghana, Accra, Ghana, [2]Emory University, Atlanta, GA, United States, [3]korle-Bu Teaching Hospital,Accra, Ghana, Accra, Ghana, [4]Morehouse School of Medicine, Atlanta, GA, United States

Hemolysis associated with malaria and sickle cell disease SCD leads to activation of vascular endothelial cells and this modulates migration and adhesion of inflammatory cells. Both diseases result in systemic elevation of free heme leading to oxidative stress and subsequent inflammation and damage to vascular endothelial cells. Previous studies have used cobalt protoporphyrin IX, PPIX to induce heme scavengers to decrease proinflammatory cytokine production in hemolysis associated diseases. However, development of appropriate models to test interventions against heme induced damage to host cells have been limited. Recent studies have revealed that a neuroprotective factor Neuregulin1, NRG1 mediates human brain vascular endothelial cell protection. We differentiated patient derived induced pluripotent stem cells iPSCs into endothelial cells ECs and used them as a model to assess vascular endothelial integrity during exposure to free heme. We hypothesized that NRG1 can modulate heme induced vascular inflammation and endothelial cell dysfunction. Blood and urine samples were used to generate iPSCs from children with SCD and malaria presenting at Korle Bu Teaching Hospital in Accra Ghana. iPSCs derived endothelial cells (iPSC-ECs) expressed CD 31 and CD144 as expected. Biomarkers associated with vascular injury Ang1&Ang2, proinflammatory chemokine and cytokines CXCL10 TNF α IL 1 IL 6 IL 10 and brain derived neurotropic factor BDNF, were assessed in plasma and compared. iPSC-ECs controls were treated with heme, PPIX and NRG1. Patient derived iPSCs from HbSS and HbAS children differentiated to ECs displayed decreased growth and cellular dysfunction under heme treatment. Moreover proinflammatory factors CXCL10 Ang2/Ang1 and BDNF increased in plasma of SCD children infected with Plasmodium falciparum. In addition, PPIX and NRG1 increased survival and proliferation of iPSC-ECs and reduced endothelial dysfunction. In conclusion our patient derived EC could be used as a model for assessing individualized vascular injury and inflammation during SCD or malaria pathogenesis and determined that NRG1 can be used to increase EC survival

5470

IDENTIFICATION OF BIOMARKERS ASSOCIATED WITH MALARIA IN PREGNANCY AND CLINICAL CORRELATION WITH OUTCOMES

Ayesha Wijesinghe, Shoaib Ashraf, Ian Lewis, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

In most tropical areas, pregnant women are at increased risk of malaria, as a consequence of the massive sequestration of parasitized red blood cells

in the placenta. Malaria in pregnancy (MiP) may alter placental functions leading to anemia, prematurity, and low birth weight. Although there are several tools to diagnose malaria infection during pregnancy, there is currently no test to assess placental dysfunction. Various biomarkers associated with placental dysfunction that are of high specificity should be studied in the context of MiP to evaluate their predictive value. Plasma and dried blood spots from a recent diagnostic clinical trial "LAMPREG" which enrolled 2500 women in Ethiopia will be used for samples and clinical data. To evaluate if there is a differential host response between symptomatic and asymptomatic women, we will measure the plasma level of the following inflammatory markers: CRP, vWF, hepcidin. Also, the gene expression of multiplex cytokines panels will be studied using droplet digital PCR in order to assess the host inflammatory response. Additionally, a metabolomic approach will be implemented to map the host response during MiP. Metabolomics will be performed using targeted and untargeted approaches, across several liquid chromatography mass spectrometry platforms. We will conduct analysis for both small molecules and lipids, to obtain a full metabolite coverage. We will use the manufacturer's built-in databases for putative identification of metabolites at the tandem mass spectrometry level.

HISTOPATHOLOGICAL CHARACTERISTICS OF DISCRETE BRAIN REGIONS DURING PLASMODIUM FRAGILE EXPERIMENTAL CEREBRAL MALARIA IN A NONHUMAN PRIMATE MODEL

James Prusak[1], Krystal Vail[2], Sydney Nemphos[1], Hannah Green[1], Sallie Fell[1], Chad Massey[3], Monica Embers[1], Robert Blair[2], Brooke Grasperge[4], Tracy Fischer[1], Andrew MacLean[2], Berlin Londono-Renteria[5], Jennifer A. Manuzak[1]

[1]Division of Immunology - Tulane National Primate Research Center, Covington, LA, United States, [2]Division of Comparative Pathology - Tulane National Primate Research Center, Covington, LA, United States, [3]Diagnostic Parasitology Core - Tulane National Primate Research Center, Covington, LA, United States, [4]Division of Veterinary Medicine - Tulane National Primate Research Center, Covington, LA, United States, [5]Department of Tropical Medicine - Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Cerebral malaria (CM) is a diffuse encephalopathy associated with the detection of Plasmodium spp. in blood. The prognosis of CM is poor, with 15-20% of cases being fatal and resolved cases often resulting in persistent neurological deficits. P. fragile has been previously used to model P. falciparum infection due to its ability to replicate severe malaria in rhesus macaques (RMs). Prior work identified the presence of P. fragile in cerebral vasculature of RMs but did not explore immune involvement or parasite burden within discrete cerebral compartments. We therefore hypothesized that P. fragile infection of RMs would result in CM pathology and differential sequestration of infected red blood cells (iRBCs) in the vasculature of distinct brain regions. An adult male RM (n=1) was intravenously inoculated with $20x10^6$ P. fragile iRBCs. Peripheral parasitemia and anemia were quantified by Giemsa staining of thin blood smears and assessment of plasma hematocrit levels, respectively. Euthanasia and terminal tissue harvest was conducted at 2.5 weeks post infection. Select brain regions were formalin fixed and paraffin embedded and stained with hematoxylin and eosin. Parasite burden in each brain region was determined by a trained veterinary pathologist by selecting 100 blood vessels and quantifying those containing hemozoin (HZ) pigment. At necropsy, peripheral parasitemia was 8.6%, plasma hematocrit was 27.1% indicating anemia, and iRBCs were observed in all brain sites. Petechial hemorrhages were observed grossly in white matter and hemorrhage was observed microscopically in the temporal cortex and the pons. Parasite burden was greatest in the cerebellum (16%), followed by the parietal lobe (11%), frontal lobe (10%), medulla (10%), temporal lobe (9%), basal ganglia (9%), occipital lobe (8%), and pons (6%). HZ was observed in iRBCs within the capillaries and white blood cells (WBCs), indicative of an ongoing immune response. Taken together, these data indicate that P. fragile infection of RMs is a suitable model for examination of CM pathogenesis. Additional studies are underway to identify the role of WBC infiltration in CM pathogenesis.

5472

COMPARISON OF PLASMODIUM FALCIPARUM GROWTH IN VITRO AND IN VIVO IN HUMANISED MICE

Katty Wadda[1], James Keeble[1], Giselle McKenzie[1], Christine Zverev[1], Rose Leahy[1], Vicky Rannow[1], Jessica Gruninger[1], Charles Olomu[1], Shaun Baker[1], Paul Bowyer[1], Sandrine Vessillier[1], Alison Kemp[2], Julian Rayner[2], Sandra Diebold[1], Adela Nacer[1]

[1]Medicines and Healthcare Products Regulatory Agency, South Mimms, United Kingdom, [2]Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom

In vitro culture has been used to study Plasmodium falciparum erythrocytic cycle for years, allowing the characterisation of genes and testing of therapies. However, it is known that P. falciparum undergoes genetic changes under continuous culture and there are limitations in the host-parasite interactions that can be explored in vitro. Humanised mice (HuMice) are immunodeficient mice that can be engrafted with human cells and tissues. They are the only small animal model that can be used to study P. falciparum in situ and may provide a unique opportunity to model human malaria infection. We have successfully established P. falciparum infections in HuMice and have used two distinct approaches to determine parasite changes in vitro and in vivo. Here we compare parasite growth and gene expression in vitro, and in vivo in the presence (HIS-RBC-HuMouse model) or absence (RBC-HuMouse model) of a human immune system. DRAG and NSG humanised mice were engrafted with either 1) human RBCs (hRBCs) alone to maintain infection in vivo (RBC-HuMouse model); or 2) with human immune cells and hRBCs to determine the effect of the human immune system (HIS) on parasite growth in vivo (HIS-RBC-HuMouse model). We established two different HIS-RBC-HuMice models to characterise changes in parasite growth in vivo. First, we used stem cells to reconstitute the human immune system (SC-HIS HuMouse model), allowing the development of functional human immune system cells including B and T cells. Secondly, we established a new approach using PBMCs (PBMC-HIS HuMouse) allowing for the reconstitution of mature immune cells. Using these approaches, we aim to use RNA-Seq to determine the gene expression of P. falciparum in these models and identify genes implicated in parasite growth in vivo. We also aim to evaluate how predictive in vitro assays for the assessment of therapeutics are in these models using monoclonal antibodies. Finally, we discuss the opportunities and limitations of each approach and outline considerations for the selection of models appropriate to research questions.

5473

GENERATION OF A PLASMODIUM BERGHEI LINE EXPRESSING A HALOTAGGED PARASITOPHOROUS-VACUOLE MEMBRANE PROTEIN TO STUDY TARGETED PROTEIN DEGRADATION DURING LIVER STAGE MALARIA

Melanie Lam[1], Ashley A. Lantigua[1], Laura Torres[1], Alexandra Probst[2], Jyothsna R. Kumar[2], Allison Torres[2], Alex Chao[2], Zacharias Thiel[3], Maude Patoor[3], Carole Manneville[3], Matthew E. Fishbaugher[2], Erika E. Flannery[2], Thierry T. Diagana[2], David Marcellin[3], Beat Nyfeler[3], Sebastian A. Mikolajczak[2], Anke Harupa-Chung[2], Gabriel Mitchell[1]

[1]Open Innovation at Novartis Institute for Tropical Diseases, Novartis Institutes for BioMedical Research, Emeryville, CA, United States, [2]Novartis Institute for Tropical Diseases, Novartis Institutes for BioMedical Research, Emeryville, CA, United States, [3]Chemical Biology & Therapeutics, Novartis Institutes for BioMedical Research, Basel, Switzerland

As malaria continues to be a global public health concern, the need for the development of novel therapeutics becomes more prominent in the face of antimicrobial resistance and difficult-to-treat infections. During the liver stage of malaria, parasites infect hepatocytes and reside within an intracellular parasitophorous vacuole (PV), which is delineated by a membrane (PVM)

and decorated by essential plasmodial proteins. These proteins sit at the host-parasite interface with their C-terminal domain exposed to the host cytosol. This project aims to provide a proof-of-concept that induced proximity can be utilized to engage host degradation processes against malaria, representing a novel avenue for the development of therapeutics. To start, we engineered a Plasmodium berghei (Pb) line that expresses a C-terminal fusion of the PVM protein UIS4 with the HaloTag (HT), a domain known to bind HaloTag ligands (HTL). The engineered transgenic parasite was genotyped using PCR, completed the malaria life cycle in a mouse infection model, and expressed the UIS4-HT fusion protein during infection of Huh7 human hepatoma cells. Using the UIS4-HT parasite along with a Halo-proteolysis-targeting chimera (HaloPROTAC) designed to bind the host E3 ligase VHL, we then asked if targeted protein degradation (TPD) can be harnessed to degrade malarial PVM proteins and disrupt the development of liver stages. Infection assays and high-content microscopy experiments demonstrated that UIS4-HT liver stages can bind to a HTL functionalized with a fluorophore and a HaloPROTAC. However, even though the HaloPROTAC was confirmed to trigger degradation of HT proteins in HEK cells, it had no detectable impact on the formation of UIS4-HT liver stages. In conclusion, this study generated and characterized a Pb transgenic parasite expressing a HaloTagged version of the PVM protein UIS4 and demonstrated its functionality at binding HTL compounds during infection. This transgenic parasite will enable mechanistic studies on TPD as well as on other induced proximity approaches during the liver stage of malaria.

5474

PATHWAYS OF MALADAPTIVE REPAIR FOLLOWING SEVERE MALARIA ASSOCIATED ACUTE KIDNEY INJURY

Anthony Batte[1], Ruth Namazzi[1], Geoffrey Situma[2], Robert O. Opoka[1], Stuart L. Goldstein[3], Chandy C. John[4], Andrea L. Conroy[4]

[1]Makerere University College of Health Sciences, Kampala, Uganda, [2]Global Health Uganda, Kampala, Uganda, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, [4]Indiana University, Indianapolis, IN, United States

Malaria is a leading cause of acute kidney injury (AKI) and a risk factor for persistent kidney disease. We leveraged a prospective cohort of children with severe malaria to identify biomarkers on admission and at one-month follow-up associated with persistent and chronic kidney disease (CKD). Between 2014 and 2017, we enrolled 600 children aged 6 months to 4 years admitted to two tertiary hospitals in Uganda. AKI was defined using the Kidney Disease: Improving Global Outcomes (KDIGO), persistent kidney disease was defined at one-month follow-up based on a 1.5-fold increase in creatinine over estimated baseline or an eGFR<90mL/min per 1.73m2 using the Bedside Schwartz equation. CKD was defined in a subset of children at 12 months follow-up. Biomarkers were tested on cryopreserved plasma samples to evaluate pathways of kidney function, tubulointerstitial stress, endothelial and immune activation. The mean age of children was 2.1 years and 43.7% were female. The prevalence of AKI on admission was 45.3% with 9.3% of survivors having persistent kidney disease at one-month follow-up. All biomarkers except for CRP, CXCL10 and IL-18 were associated with severe and persistent AKI (adjusted $p<0.05$). Of those initial biomarkers, 13 predicted persistent kidney disease following AKI (BUN, sVCAM-1, P-Selectin, Angpt-2, sFlt-1, Tenascin C, TIMP-1, Tenascin C, sIL-2R, sTREM-1, sTNR1, NGAL, OPN, TFF3). We measured biomarkers at one-month and six biomarkers were significantly associated with persistent kidney disease at one-month (P-Selectin, MMP-1, sIL-2R, sTREM-1, sTFNR1, NGAL). Biomarkers that predicted mortality over follow-up were MMP1, sTREM-1, sTNFR1 and NGAL. At one-month follow-up biomarkers of endothelial activation and tubulointerstitial inflammation were associated with maladaptive repair leading to CKD at one-year follow-up. In the present study we identified putative pathways of maladaptive repair associated with progression from AKI to CKD in children with severe malaria. Interventions targeting endothelial activation and tubulointerstitial injury represent potential targets to improve long-term kidney health.

DRIVERS OF LONG-LASTING INSECTICIDE-TREATED NET UTILIZATION AND PARASITAEMIA AMONG UNDER-FIVE CHILDREN IN 13 STATES WITH HIGH MALARIA BURDEN IN NIGERIA

Perpetua Uhomoibhi[1], Chukwu Okoronkwo[1], IkeOluwapo Ajayi[2], Olugbenga Mokuolu[3], Ibrahim Maikore[4], Adeniyi Fagbamigbe[2], Joshua Akinyemi[2], Festus Okoh[1], **Cyril O. Ademu**[1], Issa Bolakale Kawu[1], Jo-angeline kalambo[5], James Ssekitooleko[5]

[1]National Malaria Elimination Programme, Abuja, Nigeria, [2]Department of Epidemiology and Medical Statistics, College of Medicine, University of Ibadan, Ibadan, Nigeria, Ibadan, Nigeria, [3]University of Ilorin Teaching Hospital, Ilorin, Nigeria, [4]World Health Organization, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Although Nigeria has made some progress in malaria control, there are variations in progress across administrative levels (States). This study investigated the factors associated with and utilisation of long-lasting insecticide-treated net (LLIN) and parasitaemia among under-five children in 13 States with high malaria burden. Data from the 2015 Nigeria Malaria Indicator Survey and 2018 Demographic and Health Survey were analysed. The 13 study states were stratified into two based on whether they had increased or reduced parasitaemia between 2015 and 2018. Random-effects logit models were fitted to identify independent predictors of LLIN utilisation and parasitaemia. α set at 0.05. LLIN was used by 53.4% of 2844 children, while parasitaemia prevalence was 26.4% in 2018. Grandchildren (AOR=5.35, CI: 1.09-26.19) were more likely to use LLIN while other relatives (AOR=0.33, CI: 0.11-0.94) were less likely compared to direct children of household-heads. Furthermore, LLIN use was more common in children whose mother opined that only weak children could die from malaria (AOR=1.83, CI: 1.10-3.10); more likely among children whose mothers obtained net from ANC or immunisation clinics (AOR=5.30, CI: 2.32-12.14) and campaigns (AOR=1.77, CI: 1.03-3.04). Children aged 24-59 months compared to 0-11 months (AOR=1.78, CI: 1.28-2.48), those in whom fever was reported (AOR=1.31, CI: 1.06-1.63) and children of women with no formal education (AOR=1.89, CI: 1.32 - 2.70) were more likely of parasitaemia. The likelihood of parasitaemia was higher among children from poor households compared to the rich (AOR=2.06, CI: 1.24-3.42). The odds of parasitaemia were 98% higher among rural children (AOR=1.98, CI: 1.37-2.87). In conclusion, the key drivers of LLIN utilisation and parasitaemia were mainly related to socioeconomic factors. These should be targeted as part of integrated malaria elimination efforts.

UPTAKE OF FOUR OR MORE DOSES OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA DURING PREGNANCY WITH SULFADOXINE PYRIMETHAMINE (IPTP-SP) IN ZAMBIA: A SECONDARY ANALYSIS OF THE 2018 MALARIA IN PREGNANCY SURVEY DATA

Cephas Sialubanje[1], Danny Sinyange[1], Lwito S. Mutale[1], Hudson Mumbole[1], Busiku Hamainza[2], Mukumbuta Nawa[1]

[1]Levy Mwanawasa Medical University, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia

In Zambia approximately 25% of pregnant women show evidence of placental infection at delivery. The Zambian government is implementing the malaria in pregnancy (MiP) policy including intermittent preventive treatment of malaria during pregnancy with sulfadoxine pyrimethamine (IPTp-SP). However, the latest (2018) malaria indicator surveys (MIS) showed low uptake of four doses of IPTp-SP at 5%. This study determined the prevalence and predictors of the uptake of four or more doses of IPTp-SP in Zambia. We conducted a secondary analysis of the 2018 MIS dataset comprising 4, 044 women (15—49 years). The survey covered all ten provinces of Zambia. Only 1,381 (34%) women who delivered in 2018 or after the new IPTp-SP policy was introduced were included in our final sample. Descriptive statistical analysis was carried out to summarise participant characteristics and IPTp-SP uptake. Univariate

logistic regression was carried out to determine association between the explanatory and outcome variables. Explanatory variables with a p-value less than 0.20 on univariate analysis were included in the multivariable logistic regression model and crude and adjusted odds ratios along with their 95% CIs, p-value <0.05 were computed. Only 7.5% of the participants received IPTp-SP 4+. The province of residence and wealth quintile were significantly associated with uptake of IPTp-SP doses; participants from Luapula (aOR=8.72, 95%CI [1.72—44.26, p=0.009]) and Muchinga (aOR=6.67, 95%CI [1.19—37.47, p=0.031]) provinces were more likely to receive IPTp-SP 4+ compared to those from Lusaka province. Conversely, women in the highest wealth quintile were significantly less likely to receive IPTp-SP 4+ doses compared to those in the lowest quintile (aOR=0.32; 95%CI [0.13—0.79, p=0.014]). In conclusion, these findings confirm low uptake of four or more doses of IPTp-SP in the country. Preventive strategies should target women in urban provinces with low malaria transmission to ensure adherence to the IPTp-SP guidelines. Interventions should include health messages with emphasis on the new policy of four or more doses of IPTp-SP.

PREVALENCE OF MALARIA CLINICAL PHENOTYPES DURING ROUTINE CONSULTATION IN HOSPITAL DISTRICT HEALTH OF COMMUNE 4, MALI

Bourama Keita[1], Sory Ibrahim Diawara[1], Salif Coulibaly[2], Drissa Konaté[1], Seidina AS Diakité[1], Karim Traoré[1], Mariam Goita[2], Abdoul Razakou Dicko[2], Bakary Sylla[2], Abdouramane Traoré[1], Korotoumou Mallé[1], Fatoumata Kassé[1], Salimata Kanté[1], Abdourhamane Cissé[1], Khatry Mohamedou[1], Saidou Balam[1], Seydou Doumbia[1], Mahamadou Diakité[1]

[1]USTTB, Bamako, Mali, [2]Hospital district health of commune 4, Bamako, Mali, Bamako, Mali

Seasonal Malaria Chemoprevention (SMC) significantly has reduced malaria incidence in target population since its implementation in Mali in 2012. However, the recent studies have demonstrated a change in the epidemiology of malaria in the context of SMC, constituting an obstacle to its long-term implementation in Mali.This study aims to determine the prevalence of severe malaria during routine consultation at hospital district of commune 4 from July to December 2022. Sociodemographic and clinical phenotype data on malaria were collected on tablets. SPSS software version 22 was used for data analysis and Chi2 test for comparison of qualitative variables with a significance threshold at 5%. A total of 559 patients aged 0 to 15 years were enrolled. Age group 5 to15 was the most represented (51.7%) and severe malaria according to WHO definition frequency was 40%. Clinical malaria phenotype varied significantly according to age groups (48.9% in under 4 years vs. 39.4% in older children aged 5 to 15 years, p = 0.02). Severe malaria was dominated by convulsion (53.3%), followed by obnubilation 48.4%, severe anemia (41.3%), coma (34.6%), and respiratory distress (21.1%). Our data show a high prevalence of severe malaria and the need to explore association between severe malaria and Plasmodium falciparum genetic diversity in areas under SMC.

5478

ASSOCIATIONS BETWEEN ANOPHELES VECTOR DENSITY AND MALARIA INCIDENCE IN TWO ADJACENT UGANDAN DISTRICTS WITH AND WITH OUT INDOOR RESIDUAL SPRAYING

Jackson Rwatooro Asiimwe[1], Henry D. Mawejje[1], Geoffrey Otto[1], Patrick Kyagamba[1], James Adiga[1], Wilfred Odol[1], Moses Semakula[1], Ambrose Oruni[1], John Rek[1], Moses Kamya[1], Grant Dorsey[2], Paul J. Krezanoski[2]

[1]Infectious Disease Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco, San Francisco, CA, United States

Five years of Indoor Residual Spraying (IRS) with Bendiocarb and Actellic from 2014-2019 reduced malaria incidence among children in the Tororo district of Uganda from 2.96 to 0.040 episodes/person/year. A switch to clothianidin-based IRS formulations in 2020 was associated with a resurgence of malaria to pre-IRS levels. This study explores associations between Anopheles vector density and malaria incidence in two adjacent districts with and without IRS. Data was collected from September 2020 through January 2023 in 661 participants from 61 households in Tororo (IRS) and 23 households in Busia (without IRS). Individuals were followed at a study clinic and malaria was defined as fever and a positive thick blood smear. Mosquitoes were collected via CDC light traps set every two weeks in participant sleeping rooms. The exposure of interest was the mean vector density from the previous month. The outcome was whether an individual had at least one case of malaria per month. Mixed effects Poisson regression with a log-link was used to estimate the relative risk of malaria adjusted for age. In the IRS district, >1 An. funestus mosquito captured per collection was associated with a 41.8% increase in risk of malaria the subsequent month (95% CI: 24.6-61.2%; p<0.001), but was not associated with malaria in the non-IRS district. Interestingly, >1 An. gambiae s.l. mosquito was associated with a 21.9% decrease in malaria risk in the IRS district (95% CI: 10.7-31.8%; p<0.001), compared to 41.6% increased risk in the non-IRS district (95% CI: 11.3-80.1%; p=0.005). Future work will classify An. gambiae s.l. mosquitoes to the sub-species level. These findings suggest that ongoing IRS in Uganda may be leading to selection pressures with heterogeneous responses by vector species. These changes might be contributing to the malaria resurgence observed in IRS districts like Tororo which had previously achieved very low transmission.

5479

A GEOSTATISTICAL ANALYSIS OF USE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY AMONG PREGNANT WOMEN IN NIGERIA

Nihinlolawa Grace Alo[1], Alimot Amodu[2], Ezra Gayawan[2]

[1]Federal Polytecnic, Ile-Oluji, Nigeria, [2]Federal University of Technology, Akure, Nigeria

Malaria infection during pregnancy is a major public health problem in Nigeria, with substantial risks for the mother, her foetus, and the neonate. Intermittent preventive treatment of malaria in pregnancy (IPTp) is a full therapeutic course of antimalarial medicine given to pregnant women at routine antenatal care (ANC) visits to prevent malaria and maternal and foetal anaemia. In line with the World Health Organization's recommendation, Nigeria, in 2014, adopted the use of at least three doses of Sulfadoxine-pyrimethamine (SP), the recommended medicine for IPTp in the country, during ANC visits. However, data from the 2018 Nigeria Demographic and Health Survey (NDHS) and the 2021 Malaria Indicator Survey (MIS) indicate that only 17% and 31% of pregnant women respectively took the recommended dose. Relying on data from the 2013, 2018 NDHS and 2021 MIS, we used a model-based geostatistical approach within a Bayesian framework to estimate trends in IPTp-SP usage across the subnational levels of Nigeria and to determine specific locations with recorded improvements in 2018 and 2021 when compared with 2013. We further compared the pattern of usage at the subnational levels, among pregnant women who sought ANC at public and private healthcare provider. Our findings highlights Nigeria States with lagging improvements in IPTp-SP usage and the need for locally tailored interventions that will improve usage of the preventive measure across the country.

5480

MALARIA PREVALENCE IN CHILDREN WITH A HISTORY OF EXPOSURE TO SEASONAL MALARIA CHEMOPREVENTION & EXIT FROM THE TARGET: RESULTS OF A CROSS-SECTIONAL STUDY IN SOUTHERN SENEGAL

Isaac A. Manga[1], Abdoukarim Mhadji[1], Aminata Lam[1], Marie Pierre Diouf[2], Fassiath Tairou[1], Amadou Seck[1], Ekoue Kouevidjin[1], Khadime Sylla[1], Doudou Sow[3], Magatte Ndiaye[1], Oumar Gaye[1], Babacar Faye[1], Jean Louis Ndiaye[2]

[1]Parasitology-Mycology Department/FMPO/UCAD, Dakar, Senegal, [2]Parasitology-Mycology Department/UFR Santé/University Iba Der THIAM, Thies, Senegal, [3]Parasitology-Mycology Department/UFR Sante/University Gaston Berger, Saint Louis, Senegal

Seasonal malaria chemoprevention (SMC) was adopted in Senegal in 2013 and implementedin the south of the country in children aged 3-120 months. The evaluation of this strategy ismost often done in its target. This study seeks to determine the prevalence of malaria in childrenwith a history of SMC exposure and out of target.This cross-sectional study was conducted between September and December 2016 in theregions of Kédougou, Kolda, Tambacounda and Sédhiou in southern Senegal. The studypopulation was children who had exited the SMC target. The inclusion criteria were to be aged11-14 years, to have taken SMC at least once and to be apparently healthy with a negative RDTfor malaria. A questionnaire was administered and a blood sample taken for a mixed smear andblotter paper for each participant. A real-time PCR of the 18S gene were performed forPlasmodium falciparum identification.A total of 226 children, with a mean age of 11.8 (+/- 0.8) years and a sex ratio (M/F) of 1.5,were recruited in this study. The proportions of children with a history of taking SMC were33.6% for 2013, 87.6% for 2014, 38.5% for 2015 and 0.9% for 2016. The number of childrenhaving taken at least 3 monthly cycles of SMC was higher in 2013, 2014 and 2015 with 51.3%;83.3% and 82.7% respectively. The prevalence of malaria by PCR 19.46%. The proportions ofpositives were higher in children aged 11 (34.09%) and 12 (47.73%).Children who have been protected by SMC become potential reservoirs again when they leavethe target. Extension of this strategy to all the population is urgently needed.

5481

ASSOCIATION BETWEEN BEDNET USE AND MALARIA PREVALENCE BY AGE GROUP IN RARIEDA SUB-COUNTY, WESTERN KENYA, 2015-2020

Oliver Towett[1], Victoria Seffren[2], Brian Seda[1], Kelvin Onoka[1], Julie Gutman[2], Simon Kariuki[1], Feiko O. ter Kuile[3], Aaron M. Samuels[2], Titus K. Kwambai[4]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Department of Clinical Sciences, Liverpool School of Tropical Medicine,, Liverpool, United Kingdom, [4]Malaria Branch, Center for Global Health, US Centers for Disease Control and Prevention, Kisumu, Kenya

Malaria remains a leading cause of illness in western Kenya, particularly among school-aged children (5-14yrs). Identifying whether lack of insecticide-treated bednet (ITN) use by this age group is a factor driving high prevalence is important to guide targeted public health interventions. From April 2015-March 2020, year-round household surveys were conducted in Rarieda sub-county to assess malaria prevalence and ITN use. An average of 1,330 households (HH) were randomly selected to be surveyed each year. A questionnaire was administered to each HH member (or caregiver) to collect data on sleeping structure characteristics, ITN ownership and use, and self-reported fever in the past 2 weeks. Participants were tested with a pLDH/HRP2-based malaria rapid diagnostic test (RDT) irrespective of the presence of fever. Prevalence ratios were obtained by modified Poisson regression. Overall, 21,837 questionnaires and malaria tests were administered in 6,419 enrolled HH. ITN access (≥1 ITN/2 people per HH) was 41.2%. Reported ITN use the night before the survey was 81.0%: 87.5% (<5yrs), 74.7% (5-14yrs), 83.1% (15+yrs). Malaria prevalence was 29.7%: 32.0% in <5yrs, 46.1% in 5-14yrs, 18.8% in 15+yrs and 19.0% of cases reported fever in the past 2 weeks (25.1% in <5yrs; 19.8% in 5-14yrs; 15.8% in 15+yrs). Not sleeping under an ITN the night before the survey was associated with higher malaria risk (41.6% vs 27.1%, PR=1.5, 95% CI 1.4 - 1.6, p=0.001). This was significant (p=0.001) in all age groups (<5yrs: PR: 1.6 [95% CI: 1.3 - 1.7]; 5-14yrs: PR: 1.2 [95% CI: 1.1 - 1.3]; 15+yrs: PR: 1.2 [95% CI: 1.1 - 1.3]). Fever in the past 2 weeks was associated with higher RDT positivity versus those without a fever (42.9% vs 27.7%, P=1.6, 95% CI 1.5 - 1.6, p<0.001) in all age groups (<5yrs: PR: 1.7 [95% CI: 1.5 - 1.9]; 5-14yrs: PR: 1.5 [95% CI: 1.4 - 1.6]; 15+yrs: PR: 1.4 [95% CI: 1.3 - 1.6]). ITN access remains well below globally accepted targets in western Kenya. Non-use of ITNs was associated with malaria among all ages. Children 5-14yrs had the highest malaria prevalence and reported the lowest ITN use. Improving ITN access and use could help to reduce malaria prevalence in this age group.

THE PRESS TOUR: AN OUT-OF-THE-BOX APPROACH TO IMPROVE MALARIA MESSAGING IN MADAGASCAR

Joss Razafindrakoto[1], Anna Bowen[2], Laurent Kapesa[1], Solofo Razakamiadana[1], Jemima Andriamihamina[1], Mamy Rabesahala[3], Nathalie Randriamanga[4], Zoniaina Razafinarivo[4], Didier Fernando[5], Célestine Razafiarisoa[6], Omega Raobela[7]

[1]USAID-PMI, Antananarivo, Madagascar, [2]CDC, Antananarivo, Madagascar, [3]US Embassy, Antananarivo, Madagascar, [4]USAID-Impact project, Antananarivo, Madagascar, [5]USAID-Access project, Antananarivo, Madagascar, [6]Regional Health Directorate, Toamasina, Madagascar, [7]National Malaria Program, Antananarivo, Madagascar

Malaria caused 2.4 million cases and >500 deaths in Madagascar in 2021. Behaviors like using bednets and promptly seeking healthcare can reduce morbidity and mortality and the media can be a powerful channel for sensitizing the public, but journalists do not typically receive malaria-related training. We aimed to train journalists to increase the quality and quantity of malaria messaging in Madagascar. In Nov 2021, PMI Madagascar, the US Embassy Public Affairs' Office, and the National Malaria Program held a 5-day workshop for 18 journalists (7 TV, 4 radio, 5 written, 2 online) followed by 5 days of field visits to communities to learn more about malaria-related activities and concerns. In Feb 2023, we evaluated the results of this training by emailing a questionnaire to each journalist to collect the number of and references for products (articles, broadcasts, and posts on malaria) and the estimated reach per product type and outlet 12 months before and 12 months after the training, and perceptions of changes in their malaria-related knowledge and reporting quality. All 18 journalists answered the quantitative questions, while 13 answered the qualitative questions. The median number of malaria-related products per journalist increased from 1 (IQR 0-2) to 3 (IQR 2-5.8), increasing the estimated reach per journalist from a median of 15,500 (IQR 0-306, 300) to 326,185 (IQR 65,000-1,425,000) people. Among 13 journalists who responded, all reported that their approach changed from copying press releases to investigative reporting and individual storytelling. Other self-reported improvements included writing skills (10/13; 77%), knowledge of public health (11/13; 85%), knowledge of malaria (12/13; 92%), understanding of the US government role in malaria control (12/13; 92%), and importance of a community health approach to malaria control (9/13; 69%). This training was a simple way to help sensitize the public through key malaria messaging, by improving the quantity and likely the quality of malaria reporting via mass media. The results spurred the Ministry of Health to plan a similar press training on immunization and family planning in 2023.

5483

AN EXAMINATION OF NATIONAL SURVEYS AND PROGRAM REVIEWS TO DOCUMENT ACHIEVEMENT OF ANTENATAL CARE AND IPTP TARGETS IN NIGERIA

William Brieger[1], Bright Orji[2]

[1]The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Health Promotion and Education Alumni Association, College of Medicine, University of Ibadan, Ibadan, Nigeria

In 2012, the World Health Organization updated the Intermittent Preventive Treatment of malaria during pregnancy (IPTp) coverage indicator to a minimum of three doses. In 2014, Nigeria set the national target of 100% of women attending ANC to receive IPTp. This study reviewed national survey data for antenatal care (ANC) attendance and IPTp provision from the 2013 and 2018 Demographic Health Surveys (DHS) and the 2015 and 2021 Malaria Indicator Surveys (MIS). Extracted from the national malaria program reviews (MPR) of the National Malaria Strategic Plans (NMSP) of 2014 and 2019 were explanations of program implementation issues. ANC4 attendance and IPTp uptake (1st and 3rd doses) were compared using descriptive statistics. The 2015 MIS did not document ANC 4th visit, so attendance in the remaining surveys was 51%, 57%, and 52% (X2=160.0, df2, p <0.0001). The slow increase of ANC attendance and drop in 2021 meant that opportunity to acquire three IPTp doses was not possible for most women. Over the four surveys, IPT1 increased from 23% to 47% to 64%, then dropped to 58%. IPTp3 rose from 6% to 19% then dropped to 16.6% before increasing to 31% (X2= 1755, df3, p<0.0001). The MPR reports identified four factors inhibiting achievement of the ANC and IPTp targets including insecurity (terrorism, civil unrest), poor integration of malaria in pregnancy into reproductive and maternal health programs, inadequate procurement and stock-outs of SP, and logistical hurdles (lack of vehicles and fuel). By not meeting ANC4 and IPTp1 targets, limits were set for IPTp3 uptake. As other researchers have suggested, NMSPs embody global targets and may not reflect local realities. Local governments, who deliver the bulk of ANC and IPTp services, must be part of the process of setting and planning how to achieve targets.

5484

EFFECT OF BEDNETS USE ON UPTAKE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY; FURTHER ANALYSIS OF THE 2019 GHANA MALARIA INDICATOR SURVEY DATA

Samuel Bernard Ekow Harrison[1], Francis Dzabeng[2], Veronica Agyemang[1], Paul Milligan[3], Kwaku Poku Asante[1]

[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]2.West Africa Centre for Cell Biology of Infectious Pathogens, University of Ghana, Legon, Accra, Ghana, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Malaria in pregnancy constitutes a persistent public health threat in malaria-endemic areas of Africa, with substantial adverse maternal and foetal outcomes, due to low uptake of malaria preventive measures. The combined use of multiple interventions against malaria such as bednets and intermittent preventive treatment of malaria in pregnancy with sulphadoxine-pyrimethamine (IPTp-SP) is greatly recommended by WHO, to achieve maximum impact. However, the use of one intervention may influence the uptake of other interventions. This study explored the effect of bednet use on the uptake of IPTp-SP in Ghana. The data source was the 2019 Ghana Malaria Indicator Survey. Stata version 16.0 was used for data analysis. Weighted frequencies and proportions highlighted participant variables. Bednet use and IPTp-SP uptake were considered the main independent and outcome variables. Survey-adjusted bivariate and multivariate logistic regression analyses were done at 95% confidence interval and 5% level of significance. A total of 2308 women who had children within the last 12 months were involved in the analysis. Participant characteristics were such that 34.4%, 32.5% and 33.1% of respondents were aged 15-24 years, 25-34 years and 35-49 years respectively with a mean age of 29.70 years (SD = 9.65). The national uptake of 1 dose and at least 3 doses of IPTp-SP were 91.7% and 65.0% respectively. While, bednet ownership stood at 80.0%, use of bednets among pregnant women was 52.5%. The combined use of bednet and IPTp-SP was 49.0%. The determinants of uptake of at least 3 doses of IPTp-SP were attending ≥4 ANC visits [aOR = 2.59, 95% CI: 1.67, 4.03; p = 0.006] and exposure to messages on malaria in last 6 months [aOR = 1.34, 95% CI: 1.07,1.67; p = 0.011]. The use of bednets was strongly associated with twice the odds of uptake of IPTp-SP among pregnant women [aOR = 2.02, 95%CI: (1.29, 3.15); p = 0.003]. The combined use of bednets and uptake of IPTp-SP among Ghanaian women is low. Maternal use of bednet positively enhances their uptake of IPTp-SP. Interventions to improve uptake of multiple doses of IPTp-SP should also emphasize the use of bednets to achieve maximum impact.

POSITIVE EFFECTS OF INDOOR RESIDUAL SPRAYING (IRS) IN MALARIA PREVENTION IN NGOMA DISTRICT

Christine Mugeni[1]; Bede Bana[1]; Yves Bizimana[1]; Laurent[1]; Evargiste Bisanukuri [1]; Donat Niyonzima[2]; Jackeline Nyirandegeya[3]

[1]Legacy Clinics and Diagnostic, [2]Jhpiego Kigali Rwanda [3]East African Christian Collage (EECC)

In last years Rwanda has faced different health problems due to some diseases that were leading to the death and suffering, among them, we found Malaria. After the government of Rwanda identified this rising in prevalence of Malaria developed policies to reduce number of death and people affected by Malaria. The method that was used is spray of medication (IRS indoor residual spraying) in all houses that was done in 2019 and 2020. Ngoma district is in the Eastern province of Rwanda between Kirehe and Kayonza districts as well as in other part of the country the spray was done, hence it gave outstanding results in that period. This abstract describes the way malaria spraying medication was effective in prevention of Malaria in Ngoma district. The prevalence of simple malaria, severe malaria and death from malaria before home spraying and after showed there was tremendous reduction. The number shows that in two years before home spraying (2017-2018) simple malaria cases were 4 406 225 cases, severe malaria were 24 946 cases and deaths from malaria were 812 cases while after IRS the number decreases tremendously at the extent simple malaria were 1 350 479 cases, severe malaria were 7 250 cases and number of death were about 255 cases. Percentage of simple malaria cases incidence drop down from 69.35% to 30.65% while the percentage of severe malaria cases reduced from 70.94% to 29.06% and the deaths percentage of malaria cases drop down from 68.60% to 31.40% All these show that IRS should be a continuous measure to be implemented as it gave effective results.

5486

MENTORSHIP-BASED TASK-SHIFTING APPROACH FOR COMMUNITY HEALTH OFFICERS IMPROVES ANTENATAL CARE ATTENDANCE AND INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY SERVICES IN LOWER-LEVEL FACILITIES IN GHANA

Felicia Babanawo[1], Mildred Komey[2], Felicia Amoo-Sakyi[1], Amos Asiedu Asiedu[1], Wahjib Mohammed[2], Paul Boateng[2], Keziah Malm[2], Raphael Ntumy[1], Gladys Tetteh[3], Lolade Oseni[3]

[1]U.S. President's Malaria Initiative, Impact Malaria Project, Accra, Ghana, [2]Ghana Health Service, National Malaria Elimination Programme, Accra, Ghana, [3]U.S. President's Malaria Initiative, Impact Malaria project, Jhpiego, Baltimore, MD, United States

Inadequate numbers of midwives at the sub-district level remain a barrier to providing antenatal care (ANC) services in Ghana. A 2019 Community-based Health Planning Services (CHPS) policy implementation assessment revealed that only 15% of CHPS zones have resident midwives to provide ANC services, leaving out most communities. Community Health Officers (CHOs) who operate CHPS zones are trained mainly to offer essential maternal and child health services. Although CHOs have some knowledge of ANC services, they lack adequate skills to provide ANC, including malaria in pregnancy (MIP) interventions such as intermittent preventive treatment of

malaria during pregnancy (IPTp) in the communities they serve. PMI Impact Malaria collaborated with the National Malaria Elimination Program to build on other CHO capacity-strengthening efforts by introducing a mentorship-based task-shifting training approach to address the challenge. CHOs in CHPS zones without midwives received a practical-based 3-day training to gain skills in history taking, documentation, physical examination, ITN distribution, IPTp services, and case management of MIP. This training was followed by a period of mentorship by midwives from nearby facilities who were paired with the CHOs, to serve as mentors to support the CHOs in developing competence in ANC. The district mentors made facility supervisory visits 4 and 12 months after the training. A total of 185 CHOs were trained on IPTp services and case management of MIP with an overall knowledge gain of 16.5% points (average pre-test score 72.5% and post-test 89%). CHOs mobilized pregnant women through intensified education during the home visit and outreach services. They provided basic ANC to pregnant women with the support of midwives' mentors, increasing ANC attendance from 52,117 to 58,044 in 18 months. IPTp1 coverage increased from 59.9% to 75.2%, and IPTp3 increased from 29.1% to 56.5% within the same period. This pilot demonstrates that through carefully designed mentorship-based task-shifting initiatives, CHOs can be supported to provide ANC and IPTp services at peripheral health facilities.

5487

PAYMENT SYSTEM FOR COMMUNITY ACTORS DURING THE 2021 AND 2022 INSECTICIDE-TREATED NET (ITN) MASS DISTRIBUTION CAMPAIGNS IN MADAGASCAR

Andriamarovesatra Soza[1], Omega Raobela[2], Hasina Harinjaka Ramiandrisoa[2], Mohamed Patrice Diallo[1], Mickael Randriamanjaka[1], Sandy Mbolatiana Ralisata[1], Claudia Rakotonirina[1], Jocelyn Razafindrakoto[3], Laurent Kapesa[3]

[1]USAID-IMPACT project, ANTANANARIVO, Madagascar, [2]National Malaria Program, ANTANANARIVO, Madagascar, [3]U.S. President's Malaria Initiative, USAID, ANTANANARIVO, Madagascar

To prevent malaria in districts at risk, Madagascar conducted mass ITN distribution campaigns in 2021 (all 101 higher-burden districts) and 2022 (10 of 13 elimination districts). More than 91,000 community actors (authenticating agents, community health volunteer mobilizers, storekeepers, and distribution agents) and local supervisors were mobilized to implement the distribution activities. During the previous mass campaigns (2010, 2013 and 2015), community actors' allowances were sent by bank to district level and payment was made through the health facility responsible party. In 2018, the campaign's national coordination committee (NCC) attempted to process payment by mobile money, but it took two years, from November 2018 to December 2020, for community actors to get paid because of long delay in setting up the mobile payment system and far distance between payment place (cash point) and beneficiaries. During the 2021 and 2022 campaigns, to ensure timely payment of community actors, the NCC set up a hybrid payment system: i) proximity payment through civil society organizations, targeting 91,546 community actors in 2021 and 6,020 in 2022; and ii) payment by mobile money directly to 6,232 local supervisors in 2021, and 20 in 2022.As a result of this hybrid payment, 91,510 (99%) of 91,546 community actors (2021) and 5,978 (99%) of 6,020 agents (2022) who were paid via proximity payment and 6,220 (99.8%) of the 6,232 local supervisors (2021) and all 20 supervisors in 2022 who were paid via mobile money received their allowances within one month of completing their work. This payment system substantially shortened the lag between work and payment and allowed direct payment of beneficiaries without intermediaries. Through this successful experience, the National Malaria Program and its partners plan to scale up and standardize this approach for other ITN distribution activities that involve community actors.

5488

IMPACT OF KNOWLEDGE, ATTITUDES, AND PRACTICES REGARDING LONG-LASTING IMPREGNATED NETS ON THE PREVALENCE OF MALARIA INFECTION AMONG CHILDREN UNDER FIVE YEARS OF AGE IN THE DODJI-BATA DISTRICT OF SOUTHERN BENIN

Tchehoundje Benjamine Sèna

clinical research institute of Benin, Abomey-calavi, Benin

For good effectiveness of LLINs, several factors must be taken into account, including effective use, integrity, durability, and, in general, knowledge, attitudes, and practices towards LLINs. The purpose of this study was to assess household knowledge, attitudes, and practices regarding LLINs and to determine the impact of these elements on parasite prevalence among children under 5 years of age. Data were collected using an administered questionnaire based on the MIILDA User. Overall "knowledge, attitude, practice" scores are calculated and ranked using Bloom's threshold. Relationships between the independent variables and the prevalence of malaria infection are compared using a chi-2 statistical test.Of 402 children seen in the households, 199 subjects were female and 203 subjects were male .The age range of children from 12 to 59 months was the most represented. In the households surveyed, 97.96% recognized mosquito nets as a means of controlling malaria. Of the children selected, 89.80% owned a net and 89.94% of these children had spent the night before the survey under the net. Nearly 7 out of 10 households used nets throughout the year; however, the number of people occupying a net was more than 2 in 90% of the cases, which makes the nets less effective and negatively influences the malaria infection rate in this community. The malaria infection rate was 11% . Physical inspection of the fabric integrity of the LLINs seen in the households revealed a proportion of 25% with holes, while 40% of the nets seen were from the 2020 campaign and were of the Olyset Plus type. The overall knowledge, attitude, and practice towards LLINs were satisfactory in the study area. However, reinforcement of communication in the community must be done for a change of behavior such as the provision of mosquito nets for children under 5 years of age in the households. Continuation of net distribution strategies must be effective to ensure adequate coverage of households with nets to avoid an exaggerated number of people occupying a net. Ongoing monitoring and evaluation of the use and durability of LLINs should be conducted to limit misuse to reduce malaria infection rates.

5489

DETERMINANTS OF MISSED OPPORTUNITIES FOR PERENNIAL MALARIA CHEMOPREVENTION TAKING CUES FROM INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY, VITAMIN A SUPPLEMENTATION AND VACCINATION DELIVERY AMONG CHILDREN 0-24 MONTHS UNDER PROGRAMMATIC CONDITIONS: A SYSTEMATIC REVIEW

Olusola B. Oresanya[1], Seyi Soremekun[1], Michael Ekholuenetale[2], James Tibenderana[3], Joanna Schellenberg[1], Bilal I. Avan[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Malaria Consortium, Abuja, Nigeria, [3]Malaria Consortium, London, United Kingdom

Despite a World Health Organization recommendation for the use of perennial malaria chemoprevention (PMC) in endemic areas, currently only Sierra Leone implements PMC at scale. A major bottleneck to policy uptake was the limited efficacy of the original 3-dose schedule, exacerbated in real-world settings by poor implementation and coverage. Missed opportunities for PMC uptake during immunization clinics are an important contributor to poor coverage. This review, planned for June 2023, will systematically identify and synthesize evidence on possible determinants of missed opportunities for PMC drawing valuable lessons from literature on the implementation of intermittent preventive treatment in pregnancy (IPTp), vitamin A supplementation (VAS), and childhood vaccination. Searches will include electronic bibliographic databases, grey literature and bibliographies

of retrieved articles. Inclusion criteria will include: quantitative and qualitative or mixed methods research studies; studies assessing determinants of missed opportunities for IPTp, IPTi, VAS or vaccination; conducted in sub-Saharan Africa; reports and peer-reviewed or grey literature. Search concepts will include 'Intermittent preventive treatment', 'Factor', 'Barrier', 'Determinant', Infant', 'Routine immunization clinic', 'Malaria', 'Coverage', 'Vitamin A supplementation', 'Missed opportunity', 'Policy uptake' etc. Lists of titles and abstracts of articles retrieved will be exported to Endnote library and duplicates removed, and eligible full articles will be retrieved. Quality assessment of the studies will be done using relevant checklists to deal with the risk of bias. A descriptive analysis of the selected studies will be done with a narrative synthesis to bring the findings together. Data extraction will be aided by a tool and verified by a second reviewer. Pre-existing themes used by the authors will be identified and stratified based on user or provider perspectives. This review will contribute to the development of a conceptual framework for addressing missed opportunities for PMC to facilitate uptake and scale up.

5490

LOST TO FOLLOW-UP AND LOW INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCYAT ANTENATAL CARE SETTINGS IN LIBERIA

Victor S. S. Koko[1], Jethro W.S. Zawolo[2], Wahdae-mai Harmon-Gray[3], Mamadou O. Diallo[4], Jessica M. Kafuko[5], Gaspar Mbita[2], Odell Kumeh[1], Julie R. Gutman[6], Laura Skrip[3]

[1]National Malaria Control Program, Ministry of Health, Monrovia, Liberia, [2]USAID Strategic Technical Assistance for Health (STAIP), Jhpiego, Monrovia, Liberia, [3]School of Public Health, University of Liberia, Monrovia, Liberia, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Monrovia, Liberia, [5]U.S. President's Malaria Initiative, U.S. Agency for International Development (USAID), Monrovia, Liberia, [6]Malaria Branch, U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

In 2018, Liberia implemented WHO-recommended intermittent preventive treatment in pregnancy (IPTp) with sulfadoxine-pyrimethamine. The 2020 Liberia Demographic and Health Survey found that 87% of women with a pregnancy in the last four years attended at least four antenatal care (ANC) visits during their most recent pregnancy; 40% of them reported taking at least three IPTp doses (IPTp3). To assess the gap between high ANC attendance and low IPTp3 uptake, we conducted a retrospective review of ANC records of women 15-49 years old who initiated ANC between November 2020 and January 2021 at 33 randomly selected ANC sites in Bong, Nimba, and River Gee Counties. All selected ANC sites were public health facilities (clinic, health center, hospital). A woman who had ANC1 at a given site and never returned to that site was defined as lost to follow up (LTFU). We conducted multivariable logistic regression to investigate factors associated with LTFU. Among 1724 women registered for ANC1, 50% returned to the same site for ANC2, 32% for ANC3, and 19% for ANC4. Overall, IPTp3 uptake was 30% and 9% (141/1644) of women tested at ANC1 were diagnosed with malaria. Among the 878 women who returned for ANC2 services at the same site, 38% completed ANC4; of those 59% received IPTp3. LTFU ranged from 25% in River Gee to 47% in Nimba and 70% in Bong. Women with malaria were more likely to be LTFU (aOR= 1.9; 95% CI:1.3-2.9). Maternal age (aOR=1.0; 95% CI:0.98-1.3), parity (aOR=1.0; 95%, CI:0.9-1.1), ANC site (clinic aOR=1.0 [95% CI:0.8-1.4], and health center vs hospital (aOR=0.9 [95% CI:0.6-1.2]) were not associated with LTFU after ANC1. Compared to those attending ANC at hospitals, women attending ANC at clinics were more likely to receive IPTp3 (aOR= 3.4; 95% CI: 1.8-6.6). Retention in ANC was low, which impedes optimal delivery of IPTp. To improve ANC retention, it is important to better understand and address the factors that prevent women who initiate ANC from attending all recommended visits. It is also critical to understand factors contributing to missed opportunities at ANC to provide IPTp, particularly in hospital settings.

5491

THE ROLE OF COMMUNITY LEADERS IN SEASONAL MALARIA CHEMOPREVENTION: BUILDING STRATEGIES TO COMMUNITY ENGAGEMENT IN NORTHERN MOZAMBIQUE

Mercia A. Sitoe[1], Albertino Zunza[1], Ivan Tarquino[2], Sonia Enosse[2], Kevin Baker[3], Regina Passe[4], Osvaldo Jantar[4], Jossias Machava[2], Maria Rodrigues[2]

[1]Malaria Consortium, Nampula, Mozambique, [2]Malaria Consortium, Maputo, Mozambique, [3]Malaria Consortium, London, United Kingdom, [4]Ministry of Health, Nampula, Mozambique

Seasonal malaria chemoprevention (SMC) is a highly efficacious and effective intervention to prevent malaria infections in areas where the malaria burden is high, and transmission is seasonal. SMC is implemented in northern Mozambique since 2020, administering monthly courses of sulfadoxine plus pyrimethamine and amodiaquine (SPAQ) to children aged 3–59 months. Sensitization and mobilization are carried out before the distribution by community leaders, members recognized as authorities by the community, using a door-to-door approach. A qualitive study was conducted in 2021 in Nampula to assess acceptability of SMC. The presented work describes the contribution of community leaders to the implementation of the SMC campaign. Twenty key informant interviews were conducted with key stakeholders at community, provincial, national and district level and twenty focus group discussions (FGD) were carried out with caregivers of children who received SPAQ, community distributors (CD) and CDs supervisors. Thematic analysis was performed using Maxqda10 software, and themes were identified and categorized following prevalent topics. Community distributors reported that, 'community leaders went to the community to inform' caregivers about SMC medicines, thus 'they [caregivers] accepted to receive the medicine'. District officials perceived that 'the population joined in because of the community leadership' guiding and informing the community. Caregivers talked about the role of community leaders who 'recommended us to participate once the campaign started' and explained the benefits of SMC for children. Participants at community and district level reported that, community mobilization led by community leaders and their direct involvement in the SMC campaign helped deliver accurate information to communities and contributed to their acceptance of the intervention. Community leaders should be recognized authorities that can help further promote dissemination of information on, and acceptance of SMC.

5492

COVERAGE AND FACTORS ASSOCIATED WITH UTILIZATION OF PYRETHROID-PIPERONYL BUTOXIDE TREATED NETS IN MALARIA ENDEMIC REGION, WESTERN KENYA

Stephen A. Aricha[1], Maurice Owiny[1], Fredrick Odhiambo[1], Judy Mangeni[2], Elvis Oyugi[1]

[1]Ministry of Health, Kenya, Nairobi, Kenya, [2]Moi University, Kenya, Nairobi, Kenya

Increased resistance to pyrethroid based Long-Lasting Insecticidal Nets (LLINs) informed WHO recommendation to deploy Piperonyl Butoxide (PBO) based LLINs. Kenya adopted use of PBO nets in endemic areas, though coverage is not known. We determined coverage and factors associated with utilization of PBO nets in a malaria endemic county, Western Kenya. We conducted cross-sectional study with multi-stage sampling in Matayos Sub-County, Busia County. Data were collected using questionnaire from June-July 2022. Data was analyzed by Stata version 16. Universal coverage was defined as ownership of one PBO net for two household members. Proper utilization was defined as sleeping under a mosquito net the previous night, net usage on all days of the week, hanging the net adequately. Data was collected on net ownership, access, utilization. Proper utilization of nets was the dependent variable. We calculated measures of central tendency and dispersion for continuous variables and proportions for categorical variables. Chi-square was used to test for association between dependent and independent variables.

Variables with a p-value< 0.05 were considered statistically significant. A total of 402 participants were interviewed; mean age was 41.2 years (±16.7 years), 268 (66.7%) resided in rural areas, 313 (77.9%) were female, 287 (71.4%) were married, 181 (45%) had formal education and 348 (86.6%) had informal occupations. Among all respondents, 347 (86.3%) had nets, 92.8% (322/347) were PBO and 261 (64.9%) households attained universal coverage. The odds of a household utilizing a PBO net if the household head had informal occupation was 71% less than households whose head had formal occupations (aOR=0.29, 95% CI=0.11-0.78). The odds of households that had not attained universal coverage utilizing a PBO net was 99.9% less than households that had attained universal coverage (aOR=0.01, 95% CI=0.01-0.03). Universal coverage of PBO nets was below the national target. Informal occupation and universal coverage were found to be associated with the utilization. We recommend continuous distribution of nets through additional innovative channels.

5493

PSYCHOSOCIAL FACTORS INFLUENCING INSECTICIDE-TREATED NET USE AND CARE IN LIBERIA

Joseph Millward[1], Victor S. Koko[2], Odell Kumeh[2], Ben Kitson[3], Liwenan Li[1], Eric Gaye[3], Vivian Nyankun[3], Eric Filemyr[1], Mamadou O. Diallo[4], Stella Babalola[1], Catherine Harbour[1]

[1]Breakthrough ACTION Project, Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [2]National Malaria Control Program, Ministry of Health, Monrovia, Liberia, [3]Breakthrough ACTION Liberia Project, Johns Hopkins Center for Communication Programs, Monrovia, Liberia, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Monrovia, Liberia

In Liberia, which has year-round malaria transmission, ownership and use of insecticide-treated nets (ITN) is a key strategy for malaria control. To assess the association of psychosocial determinants with consistent ITN use (i.e., daily) and net care (i.e., tying up nets when not in use), Breakthrough ACTION and the National Malaria Control Program conducted a Malaria Behavior Survey in 2021. Standard questionnaires were administered to 5822 individuals (4677 women and 1145 of their male partners) from 3719 households. Psychosocial factors, including attitudes towards nets, confidence in one's ability to use a net every night, and perceptions of others' use of nets (norms), were assessed based on agreement with a series of statements. Responses were scored (1 for agreement, 0 for uncertainty, and -1 for disagreement) and summed into factor-specific scales. Scale scores greater than 0 defined presence of relevant psychosocial factors. In 2454 households with at least one net (66%), 4192 (72%) and 4308 (74%) respondents reported consistent use and tying up nets when not in use, respectively. In multivariate regression, factors associated with consistent net use included favorable attitudes towards ITN use (OR: 2.1, 95% CI: 1.6-2.7), confidence in one's ability to use a net every night (OR: 7.4, 95% CI: 5.8-9.5), and perceived community use (OR: 1.4, 95% CI: 1.1-1.6). Factors associated with net care included knowledge that nets can prevent malaria (OR: 1.3, 95% CI: 1.1-1.6) and favorable attitudes towards both net use (OR: 2.1, 95% CI: 1.7-2.8) and net care (OR: 2.3, 95% CI: 1.2-4.3). Net sufficiency (1 net per 2 household members) was not correlated with consistent net use; however, each additional net reported in a household was associated with increased net care (OR: 1.1, 95% CI: 1.0-2.3). These results suggest that interventions to promote favorable attitudes towards nets, strengthen confidence in one's ability to use nets consistently, and strengthen community norms may increase consistent net use. Net care may sustain household supplies of nets; interventions should seek to increase positive attitudes towards nets to boost net care.

5494

PREVENTION OF MALARIA IN PREGNANT WOMEN AND ITS EFFECTS ON MATERNAL AND CHILD HEALTH, THE CASE OF CENTRE HOSPITALIER DE KINGASANI II IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Japhet Kabalu Tshiongo, Trésor Zola Matuvanga, Patrick Mitashi, Hypolite Muhindo Mavoko, Junior Matangila Rika

University of Kinshasa, Kinshasa, Congo, Democratic Republic of the

During pregnancy, malaria causes life-threatening outcomes to the mother and the newborn. The strategies to control malaria during the pregnancy rely on management malaria cases and anemia, and preventive measures such as intermittent preventive treatment with sulfadoxine-pyrimethamine (IPTp-SP) and the use of insecticide-impregnated mosquito nets (ITN). Therefore, this study aimed to provide updated data of the benefit of ITN and IPTp-SP on the birth weight of the newborn and the hemoglobin level of the mother. This cross-sectional analytical study was conducted among 467 women in labor in the Maternity of Centre Hospitalier de Kingasani II, in Democratic Republic of the Congo. Data collection was conducted using a structured questionnaire that was pre-tested in a face-to-face interview. The chi-square test was used to compare the proportions. Multivariate analysis (logistic regression) was also used to identify variables significantly associated to IPTp-SP compliance, ITN use, low birth weight and to maternal anemia, with the 95% of the confidence interval. The ITN ownership rate was 81% (95%CI: 77-84) and the ITN use rate was 66% (95% CI: 62-70). Sixty-five percent (95% CI: 60-69) reported having received at least three doses of IPTp-SP. Mothers who used ITN had a higher hemoglobin level compared to those who did not (9.4mg/dl IIQ: 8.7-9.9 versus 11mg/dl IIQ: 9.8-12.2, p=0,026). The non-use of the ITN was associated with low birth weight (aOR=3: 2.1-6.2; p< 0.001) and anemia in pregnant women (cOR =2.41: 1.16-5.01; p=0.01). The use of the ITN and taking at least 3 doses of IPTp are associated with good birth weight. The number of doses of IPTp received during antenatal care is associated with the maternal hemoglobin level in the third trimester of pregnancy. Additional strategies to improve IPTp-SP coverage and compliance may reduce maternal anemia associated with malaria during pregnancy.

5495

INCREASED MALARIA INCIDENCE FOLLOWING IRRIGATION PRACTICES IN THE ENDORHEIC RIFT VALLEY BASIN OF SOUTH ETHIOPIA

Dawit Hawaria Logita[1], Solomon Kibret[2]

[1]Hawassa University, Hawassa, Ethiopia, [2]California Department of Public Health, West Valley Mosquito and Vector Control District, Ontario, CA, United States

Water resource development practice such as irrigation is key to ensuring economic growth and food security in developing countries. However, vector-borne diseases like malaria spread linked to such development have been a concern. The study was done to determine the impact of irrigation on malaria incidence and vector mosquito abundance in southern Ethiopia. Eight years of malaria morbidity data were extracted from the medical registers of health facilities, and mosquitoes were surveyed in both irrigated and non-irrigated settings. Malaria incidence, case distribution across age and sex, seasonality, parasite proportion, and mosquito density were analyzed and compared between irrigated and non-irrigated settings. The result showed that annual mean malaria incidence was 6.3 higher in the irrigated (95% CI: 0.7 – 33.6) than in the non-irrigated settings (95% CI: 1.2 – 20.6). Although a remarkable decline in malaria incidence was observed for three successive years (2013 - 2017), a significant resurgence between 2018 and 2020 was noted following the introduction of irrigation schemes. The densities of adult Anopheles mosquitoes were 15-fold higher in the irrigated settings compared to non-irrigated. Higher malaria incidence coupled with enhanced adult Anopheles density in the irrigated villages has important implications for designing tailored control interventions in such development settings

5496

UNBOUND PIPERAQUINE EXPOSURE IN CHILDREN AND PREGNANT WOMEN RECEIVING DIHYDROARTEMISININ-PIPERAQUINE AS MALARIA CHEMOPREVENTION

Dihydroartemisinin-piperaquine (DHA-PQ) is highly effective for malaria chemoprevention, but standard dosing is based on pharmacokinetic (PK) data from non-pregnant adults, which may not be optimal for children and pregnant women. We previously reported that PK exposure of PQ is reduced significantly in the context of childhood development, pregnancy, and efavirenz (EFV)-based antiretroviral therapy. However, as PQ is >99% protein-bound, it is important to assess potential alterations in protein binding during childhood development and pregnancy which may lead to changes in the pharmacologically active unbound drug fraction (fu) relative to total PQ. We therefore investigated the fu of PQ in children, pregnant women, and those receiving EFV to inform PK interpretation of changes in total drug exposure. Plasma samples from 0 to 24 hr after the third chemoprevention dose of DHA-PQ were collected in children at 32 and 104 wks of age, pregnant women at 28 wks gestation receiving or not receiving EFV-based antiretroviral therapy, and women 34-54 wks post-partum not receiving EFV (control adults). Unbound PQ was quantified via ultrafiltration and liquid chromatography-tandem mass spectrometry, with fu calculated as PQunbound/PQtotal. The geometric mean fu was 27% ($p<0.0001$), 38% ($p<0.0001$), and 23% ($p<0.0001$) greater in children at 32 and 104 weeks of age, and pregnant women receiving EFV, respectively, compared to that in control adults. The fu did not differ between pregnant and control adults ($p=0.66$). Altered PQ fu is potentially due to developmental changes in children impacting protein concentrations and binding capacity and PQ displacement from plasma proteins by EFV. These results indicate that an increase in PQ fu modestly compensates for the significant decrease in total PQ exposure we previously reported. This appreciation should be considered if optimizing dosing guidelines based on total PQ PK results. Further study during the terminal elimination phase (e.g. on day 28 post-dose) would help better characterize unbound PQ exposure and thus the overall efficacy of PQ for malaria chemoprevention in these special populations.

RECEIPT OF SEASONAL MALARIA CHEMOPREVENTION BY AGE-INELIGIBLE CHILDREN AND ASSOCIATED FACTORS IN NINE IMPLEMENTATION STATES IN NIGERIA

Taiwo Ibinaiye[1], Kunle Rotimi[1], Chibuzo Oguoma[1], Adaeze Aidenagbon[1], Ayodeji Balogun[1], Kevin Baker[2], Christian Rassi[2], Chuks Nnaji[2], Olabisi Ogunmola[1], Olusola Oresanya[1]

[1]Malaria Consortium, Abuja, Nigeria, [2]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention (SMC) has rapidly been scaled up in Nigeria, reaching nearly 27 million children in 2022. As part of implementation quality standards, SMC community distributors are expected to ensure that only age-eligible children (aged 3 - 59 months) receive SMC medicines during the monthly distribution cycles. However, difficulties in determining children's age and caregivers' desire for older children to receive protection from malaria, among other factors, may lead to older children receiving SMC medicines. We extracted data from a 2022 end-of-round SMC household representative surveys and analyzed data of 3,299 caregiver-child pairs sampled from nine SMC-implementing states in Nigeria. Mixed-effects multivariable logistic regression models were fitted to explore the association between receipt of SMC by age-ineligible children and covariates. The mean age (±SD) of the children was 6.4 (1.4) years, 30.3% (95% CI: 27.8 - 32.9) of whom received at least one dose of SMC medicines in 2022. The majority (60.6%) of the over-age children who received SMC medicines were aged 5-6 years, while 19.5% were 7-year-olds and the rest (19.9%) were aged 8-10 years. We observed higher odds of an age-ineligible child receiving SMC among caregivers who had poor knowledge of SMC age of eligibility (OR: 1.8, 95% CI: 1.2 - 2.6, $p=0.002$), compared with those who had good knowledge of the age of eligibility. Notably, higher odds of receipt of SMC were also found among age-ineligible children whose caregivers had high confidence in SMC (OR: 2.3, 95% CI: 1.3 - 4.2, $p=0.007$), compared with those whose caregivers had low confidence in SMC. It was also found that age-ineligible children whose caregivers were older had lower odds of receiving SMC than those whose caregivers were younger. The study shows that a substantial proportion of age-ineligible children received SMC, with important implications for SMC implementation fidelity, effective coverage, impact and cost-effectiveness. The findings underscore the need for prioritizing programmatic quality improvement strategies to minimize the administration of SMC to ineligible children.

ASSESSMENT OF HEALTH SYSTEM'S FUNCTIONALITY AND READINESS FOR PERENNIAL MALARIA CHEMOPREVENTION IMPLEMENTATION IN OSUN STATE, NIGERIA

Michael Ekholuenetale[1], Yahya Hamzat[2], Chinazo Ujuju[1], Semiu Rahman[1], Mary Abosede Adekola[2], Kolawole Maxwell[1], Olusola Oresanya[1], James Tibenderana[3]

[1]Malaria Consortium, Abuja, Federal Capital Territory, Nigeria, [2]Malaria Consortium, Oshogbo, Osun State, Nigeria, [3]Malaria Consortium, London, United Kingdom

Malaria is a major cause of childhood mortality in many parts of the world. Prevention, diagnosis, and treatment are essential to reduce its impact. Most Nigerians are susceptible to malaria, which continues to be a public health issue despite advancements over the past two decades. PMC with sulfadoxine pyrimethamine (SP) is recommended by World Health Organization for the prevention of malaria in children <24 months to reduce the disease burden and death due to malaria. The implementation of PMC is critical for reducing malaria burden, improving health and promoting sustainable development. We assessed the health system's functionality and readiness for the deployment of PMC in Osun state, Nigeria looking at malaria cases data, uptake of childhood immunization, availability and training of health care workers on service delivery, data capturing and reporting. A cross-sectional random sample of 105 health facilities (public and private) was selected to extract data from the National Health Management Information System (NHMIS) registers on parameters of functionality and readiness between 2021-2022. We established a trend for malaria cases in the first year of life, which increased as the age of the children increased and peaked at 12 months. Approximately 96.8% of PHCs diagnosed malaria using rapid test kits, while about 16.0% confirmed malaria diagnosis using microscopy and 9.6% use clinical diagnosis. A decreasing pattern in the number of children who were vaccinated from birth up to 15 months was observed. The majority of health facilities reported having at least one health worker who has been trained on: immunization (96.1%), vaccine management/handling and cold chain (94.8%), data reporting (93.5%), disease surveillance and reporting (84.4%) and monitoring of service delivery (83.1%) in the past 2 years. The findings showed the distribution of uncomplicated malaria cases, which could help to determine where to place touchpoints for SP administration during PMC implementation. A sustainable strategy is required to prevent drop-outs in children who initiate childhood vaccination.

5499

INSECTICIDE TREATED NETS (ITNS) USE AND MALARIA PREVALENCE AMONG CHILDREN UNDER FIVE IN NIGERIA

Henrietta O. Owie - Olapeju[1], Ibrahim B. Adigun[2]

[1]The University of Sheffield, Sheffield, United Kingdom, [2]University of Ilorin, Ilorin, Nigeria

Malaria poses a greater risk to children under the age of five years due to its high morbidity and mortality. Nigeria contributes 27 percent to the malaria burden and 32 percent to the malaria deaths. Insecticide - Treated Nets (ITNs) use has been proven to be an effective preventive intervention for the control of malaria. We examined the relationship between the utilization of ITNs and the prevalence of malaria in children under five in Nigeria. Data were drawn from the most recent (2021) Demographic and Health Surveys (DHS). Logistic regression was used to analyze and establish the relationship between ITN use and malaria positivity (from blood smear result), controlling for wealth index, urban/rural residence, child's age in months, sex of the child, ITN use, geographic region, sex of head of household, age and education level of the mother. The study included 10,717 children under five with a blood smear test result- 27% urban and 73% rural. Only 38% of children under five used an ITN while 40% tested positive for malaria. Of note, the child under five sleeping under a net was not associated with malaria positivity (AOR: 1.06; 95% CI: 0.91-1.22). Factors associated with malaria positivity included increasing wealth quintile (AOR ranging from 0.18 to 0.59), geographic regions (AOR ranging from 1.47 to 1.63, 95% CI), child age in months (AOR: 1.02; 95% CI: 1.02-1.03), child's sex (AOR: 0.87; 95% CI: 0.78-0.96). Study findings suggest that malaria positivity may be influenced by multifaceted factors from the individual to the community/regional level. Community-level ITN use may be a better correlate of malaria prevalence than individual net use in Nigeria. Observed socioeconomic differences including wealth quintile, region, and maternal education level suggest that there may be underlying inequities among children under five that need to be addressed with targeted interventions in order to ensure malaria prevention in a heterogeneous setting like Nigeria.

5500

ENTOMOLOGICAL INDICES PREDICT PARASITOLOGICAL MALARIA TRANSMISSION INDICES ACROSS VILLAGES IN WESTERN KENYA

Brenda Omala[1], David Mburu[2], Maurice Ombok[1], Vincent Moshi[1], John Gimning[3], John Grieko[4], Nicole Achee[4], Benard Abong'o[1], Eric Ochomo[1]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Pwani University, Mombasa, Kenya, [3]Centre for Disease Control and Prevention, Atlanta, GA, United States, [4]University of Notre Dame, Notre Dame, IN, United States

Understanding the underlying relationship between malaria entomological and epidemiological indices could be useful in utilizing one as a predictor of the other to inform the transmission spectrum. This is important for evaluation of new interventions and policy. In this study we evaluated how well entomological indices of Anopheles densities, human biting rate (HBR), entomological inoculation rate (EIR) could be associated with malaria test positivity rates in Western Kenya. The collection of mosquito vector species was done using CDC light traps in five rural villages of Teso South sub-County in Busia County. The health facility under-five and over-five outpatient department (OPD) register datasets for the period March and June 2021 was extracted from the health facilities and used to calculate malaria test positivity rates for each of five villages in this study. Vector species densities, human biting rate (HBR) and entomological inoculation rates (EIR) were calculated using standard methods for each of the villages. Multilevel models were then run in R statistical software to determine the association between entomological and epidemiological indices. Significant association was observed between epidemiological indicator (malaria test positivity) and anopheline mean density (OR 1.12, 95% CI 1.08 - 1.16), HBR (OR 1.37, 95%CI 1.19 - 1.57). No significant association was observed between epidemiological indicator (malaria test positivity) and EIR (OR 1.04, 95% CI 0.96 - 1.13). The study results suggest that there is an association between malaria test positivity rate and entomological indices of mean densities, HBR but not EIR and therefore these measures can be used as proxies for test positivity rates.

5501

QUANTIFYING SPATIAL HETEROGENEITY OF MALARIA IN THE ENDEMIC PAPUA REGION OF INDONESIA: ANALYSIS OF EPIDEMIOLOGICAL SURVEILLANCE DATA

Ihsan Fadilah[1], Bimandra Djaafara[2], Karina Lestari[1], Sri Fajariyani[3], Edi Sunandar[4], Billy Makamur[4], Berry Wopari[5], Silas Mabui[5], Lenny Ekawati[1], Rahmat Sagara[1], Rosa Lina[1], Guntur Argana[3], Desriana Ginting[3], Maria Sumiwi[6], Ferdinand Laihad[7], Ivo Mueller[8], Jodie McVernon[9], Kevin Baird[1], Henry Surendra[1], Iqbal Elyazar[1]

[1]Oxford University Clinical Research Unit Indonesia, Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia, [2]Medical Research Council Centre for Global Infectious Disease Analysis, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [3]Sub-Directorate for Malaria Control, Ministry of Health, Jakarta, Indonesia, [4]West Papua Provincial Health Office, Papua Barat, Indonesia, [5]Papua Provincial Health Office, Papua, Indonesia, [6]Directorate General of Public Health, Ministry of Health, Jakarta, Indonesia, [7]United Nations Children's Fund Indonesia Country Office, Jakarta, Indonesia, [8]Division of Population Health and Immunity, Walter and Eliza Hall Institute, Melbourne, Australia, [9]Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia

As control efforts progress towards elimination, malaria is likely to become more spatially concentrated in few local areas. The purpose of this study was to quantify and characterise spatial heterogeneity in malaria transmission-intensity across highly endemic Indonesian Papua. We analysed individual-level malaria surveillance data for nearly half a million cases (2019-2020) reported in the Papua and West Papua provinces and adapted the Gini index approach to quantify spatial heterogeneity at the district and health-unit levels. In this context, high Gini index implies disproportionately distributed malaria cases across the region. We showed malaria incidence trends and the spatial and temporal distribution of sociodemographic characteristics and aetiological parasites among cases. While Papua province accounted for the majority of malaria cases reported in the region and had seen a rise in transmission since 2015, West Papua province had maintained a comparatively low incidence. We observed that Gini index estimates were high, particularly when the lower spatial scale of health units was evaluated. The Gini index appears to be inversely associated to annual parasite-incidence, as well as the proportions of vivax malaria, male sex, and adults. This study suggests that areas with varying levels of transmission-intensities exhibited distinct characteristics. Malaria was distributed in a markedly disproportionate manner throughout the region, emphasising the need for spatially targeted interventions. Periodic quantification and characterisation of risk heterogeneity at various spatial levels using routine malaria surveillance data may aid in tracking progress towards elimination and guiding evidence-informed prioritisation of resource allocation.

IMPROVING EVIDENCE FOR ACTION: LESSONS FROM PANAMA'S SUCCESSFUL EFFORTS TO STRENGTHEN CASE-FINDING AND CASE-REPORTING

Lizbeth Cerezo-Góndola[1], **Carmela M. Jackman Smith**[1], Juan G. Rodríguez[1], Pastor Muñoz[1], Rufino Bejarano[1], Lourdes E. Moreno-Castillo[1], Justin T. Lana[2], Christina A. Bradley[2], Jorge O. Cano-Torres[2]

[1]Ministry of Health, Panama City, Panama, [2]Clinton Health Access Initiative, Panama City, Panama

In 2022, Panama reported just over 7000 malaria cases, continuing the year-over-year increase that began in 2018 when just 735 cases were reported. Alongside this ~10-fold rise in reported cases are significant improvements in case-finding and case-reporting. Two major milestones

include: (1) the introduction of rapid diagnostic test available to Community Health Workers (CHWs) in 2017 and Vector Control Technicians in 2019 (referred as community testing (CT)), in hard-to-reach and highly endemic, Indigenous communities and (2) the national roll-out of a nominal, locality-level electronic surveillance system (SISVIG) and visualization dashboard (DHIS2) in 2020. We performed a review of key indicators obtained from SISVIG/DHIS2, describing improvements in case management, timeliness of case notification, and completeness of case records. Our results showed that in 2022, more than 44,000 diagnostic tests were reported nationwide, representing a modest 8% increase in overall testing compared to 2018. However, the number of tests conducted by CHWs increased 6-fold over the same time, accounting for 17.2% of tests in 2022. CT impact was especially apparent in the Panama Este region where regional health staff efforts to maintain high testing and adequate stock levels contributed to a 60% decline in reported cases in the final 6 months of 2022 compared to the same period the year before; the 3 remaining endemic regions increased by 63% during this time. The surveillance review showed that time between case detection and case notification decreased nearly 3x; from 74 days in 2020 to 27 in 2022. As a result, national decision-makers are better positioned to enact strategies based on readily available, real-time data. Ongoing (2023) efforts to maintain a high number CT through the low season, provide effective and complete treatment, routinely perform control slides, and proportionately target locality level interventions based on recent burden can be directly linked to enhanced surveillance. Lessons from Panama's experience improving evidence to inform case-reducing actions can guide countries with equally ambitious elimination goals.

5503

ASSESSING THE QUALITY OF MALARIA DATA REPORTED IN THE DISTRICT HEALTH INFORMATION SYSTEM VERSION 2 AND FACILITY REGISTERS IN GHANA

Godwin Afenyadu[1], Samuel Owusu[1], Duvor Ferguson[2], Wahjib Mohammed[2]

[1]Country Health Information Systems and Data Use (CHISU) Program, Accra, Ghana, [2]National Malaria Elimination Program, Ghana Health Service, Accra, Ghana

Accurate, timely and consistent data are essential for decision-making in health care. Ghana's malaria data is first recorded in paper registers and collated into paper reporting forms at the facility level, and subsequently entered in District Health Information System Version 2 (DHIMS2). In 2022, Ghana's malaria data reporting accuracy in DHIMS2 ranged from 90%-100%. However, the reported data from this hybrid electronic and manual system has not been verified. In support of the Ghana NEMP, the USAID-funded CHISU program conducted a Data Quality Audit using the WHO Data Quality Review (DQR) methodology in 25 healthcare facilities in eight districts from three regions. In each region, the districts with the highest and lowest reporting accuracy scores were sampled (facilities selected randomly). Data from five outpatient department malaria care variables from the previous three months were audited for accuracy and sources of data errors. The verification factors computed were categorized as either within-accuracy-range of 95% - 105% or out of the accuracy range, incorporating a margin of ±5% error of perfect congruence of 100% on the verification factor. The proportion of verification factors within-accuracy-range was then expressed as a percentage of both within-range and out-of-range. The cumulative accuracy score of Facility Register (paper) against DHIMS2 Verification was 45.9%. The accuracy score of Register (primary source) and Reporting forms (paper) was 47%; the score for Reporting forms (paper) and DHIMS2 data was 83%. Data inaccuracy occurred most during tallying and aggregation of data from the registers onto the reporting forms at the facility level. Sources of errors included use of improvised and outdated registers, lack of standardized tally sheets, data transcription errors, and inability of district hospitals' EMR to generate accurate reports. Based on these findings, CHISU recommends for GHS to make standardized registers/ tally sheets available in the short term and train staff appropriately, and to invest in facility-level register digitization in the long term.

5504

EARLY EFFECT ASSESSMENT OF MALARIA COMMUNITY CASE MANAGEMENT (MCCM) INTERVENTIONS ON THE BURDEN OF MALARIA IN FACILITIES IN TANZANIA

Joseph Joachim Joseph[1], Patrick Gulinja[2], Mwaka Kakolwa[2], Kanuth Dimoso[2], Kefas Mugittu[2], Muhidin Mahende[2], Happiness Nyanda[3], Benjamin Winters[1], Samwel Lazaro[4], Sijenunu Aaron[4], Franky Chacky[4], Abdallah Lusasi[4], Claud John[5], Lulu Msangi[6], Naomi Serbantez[6], Dunstan Bishanga[2], Francis Levira[2], Onesmo Mwegoha[4]

[1]Shinda Malaria Project, Akros, Montana, USA, MT, United States, [2]Shinda Malaria Project, Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [3]Shinda Malaria Project, Health Information Systems Program, Dar es Salaam, Tanzania, United Republic of, [4]National Malaria Control Program, Ministry of Health, Dodoma, Tanzania, United Republic of, [5]Ministry of Health, Dodoma, Tanzania, United Republic of, [6]U.S. President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, Tanzania, United Republic of

Malaria remains a significant public health challenge in Tanzania, with high rates of morbidity and mortality among pregnant women and children under age five years. Tanzania initiated malaria Community Case Management (mCCM) in June 2022 in hard-to-reach communities with the highest burden, enabling community-based testing and treatment of uncomplicated malaria and timely referral of severe malaria to neighboring health facilities. Our aim was to assess the early effect of mCCM interventions on the burden of malaria in health facilities. We compared the number of attendees and confirmed malaria cases in outpatient departments (OPD) and the test positivity rate (TPR) between 46 facilities located in villages with mCCM and 464 facilities located in villages without mCCM across 8 councils during two time periods between July and December in 2021 (pre-mCCM) and 2022 (during mCCM). Routine facility malaria data were extracted from the District Health Information System-2 and analyzed. Between July and December 2022, a total of 11,655 patients were tested by malaria rapid diagnostic test through mCCM in the 8 councils. Among these, 3,142 tested positive (community TPR=27.0%). In facilities located in mCCM villages, OPD attendance per 1000 population decreased by 19 visits, from 195 in 2021 to 176 in 2022 (p-value < 0.001). The TPR increased from 26.4% in 2021 to 28.5% in 2022 (p-value <0.001). In contrast, OPD attendance per 1000 population decreased by 12 visits, from 219 in 2021 to 207 in health facilities in the same councils but located in villages without mCCM (p-value <0.001). The TPR also decreased from 33% in 2021 to 31% in 2022 (p-value <0.001). The difference in difference model showed 2.2% additional increase in TPR in mCCM compared to non-mCCM between the two periods (p-value= 0.035). While the changes in the selected indicators before and after mCCM implementation in the two populations were statistically significant, the differences were too small to remark on the effectiveness of mCCM on healthcare use. Further research is needed to evaluate the long-term impact of mCCM on malaria burden and healthcare use in Tanzania.

5505

USING DATA FROM PREGNANT WOMEN IN MALARIA SURVEILLANCE: WHO IS MISSING?

Cameron Taylor[1], Lenka Benova[2], Josefien van Olmen[3], Roger Tine[4], Yazoume Ye[5]

[1]The DHS Program, ICF, Rockville, MD, United States, [2]Institute of Tropical Medicine, Antwerp, Belgium, [3]Faculty of Medicine and Health Sciences University of Antwerp, Antwerp, Belgium, [4]Faculty of Medicine, University Cheikh Anta Diop, Dakar, Senegal, [5]ICF, Rockville, MD, United States

To address the challenge of monitoring malaria infection at the community level, pregnant women attending antenatal care (ANC) are proposed as a pragmatic surveillance sentinel group. Malaria screening during ANC provides a measure of the malaria burden among pregnant women but also a proxy for infection levels for children under age 5. According to the 2021 World Malaria Report, 74% of women used ANC services at least once during their pregnancy. While this is high, ANC utilization differs by area,

wealth, and other factors. ANC users are not representative of all pregnant women. If countries were to adopt an ANC malaria surveillance strategy, it is essential to know if malaria prevention behaviors of women who attended ANC are different than those who did not attend ANC. This analysis used data from Demographic and Health Surveys (DHS) and Malaria Indicator Surveys (MIS) in 27 countries in sub-Saharan Africa between 2013-2021 capturing 185,697 women. The outcome of interest is use of an insecticide treated net (ITN) by women the night before the survey. The analysis includes a weighted descriptive pooled statistic and individual country weighted logistic regression models adjusting for age, residence (urban/rural), wealth quintile, education, parity, prior death of a child, and malaria endemicity. Among women age 15-49 who had a live birth in the five years preceding the survey, 10.5% (95% CI: 10.0%-10.9%) did not attend ANC for their most recent live birth. Only 9% of women who did not attend ANC slept under an ITN the night before the survey, compared to 52% of those who had any ANC. Results of the adjusted individual country regression analysis showed that those who slept under an ITN were significantly more likely to have attended ANC as compared to those who slept under an ITN in 18 of the 27 countries (p-value <0.05). This analysis provides additional insights into the malaria prevention behaviors of women who did not attend ANC as compared to those who attended ANC. Malaria surveillance systems need to take this difference into account as the malaria prevalence among those that attended ANC is likely to be lower than those who did not attend ANC.

5506

PRIVATE SECTOR INVOLVEMENT IN THE FIGHT AGAINST MALARIA IN MADAGASCAR

Ilo Andriamanamihaja[1], Omega Raobela[2], Yvette Razafimaharo[2], Sandy Mbolatiana Ralisata[1], Soza Andriamarovesatra[1]

[1]PSI, Antananarivo, Madagascar, [2]Madagascar Ministry of Public Health, Antananarivo, Madagascar

In Madagascar, 405,605 people with fever sought care in private health facilities in 2022 compared to 290,000 in 2018. The NMF3 (Nouveau Modele de Financement phase 3) private sector program aims to increase private sector provider adherence to national malaria control guidelines in Madagascar, with a focus on stocking and using RDTs, prescribing ACTs and injectable artesunate according to guidelines, and selling LLINs. This program covers all 23 regions of the country. The Ministry of Health (MOH), the National Malaria Control Program (NMCP), the Regional Council of the Physicians Order (CROMs) and PSI Madagascar collaborated to integrate private health centers (PHCs), pharmaceutical wholesalers, pharmacies and drug depots into the national health system. Six health promoters and an mRDT quality supervisor work with the MOH and NMCP teams to conduct regular formative supervision using a provider behavior change communication approach and Medical Detailing, an approach to positively influence the providers fever and malaria management behaviors. Experts also provide continuing medical education to private providers. The program initially gave a 90% subsidy for ACTs, but the subsidy reduced to 60% in phase two. Malaria Rapid Diagnostic Test (RDT) orders by the pharmaceutical wholesalers has been stable since 2018. However, ACT orders reduced from 7,698 425,00 in 2018 to 1,492,550. In 2022, in the 551 PHCs supported by the NMF3 program, 97% of suspected malaria cases were tested compared to 70% in 2018, and 94.36% of confirmed cases were treated appropriately compared to 86% in 2018. 80% of the PHCs use the national external consultation register, and 200 of these centers (36%) are registered in the national reporting system and report into DHIS2.The project has had a positive impact on the continued availability of antimalarial commodities and improved case management, and the integration of private sector data and reports into the national reporting system. The next steps in 2023 are to continue to improve provider performance, register 100% of the 551 PHCs in DHIS2 and to increase the number of targeted PHCs to 650.

5507

MALARIA SERVICES SUPERVISIONS ACCELERATE DECLINE IN MALARIA-RELATED DEATHS IN CHILDREN UNDER FIVE YEARS IN TANZANIA: A QUASI-EXPERIMENTAL STUDY

Dunstan R. Bishanga[1], Frank Chacky[2], Abdallah Lusasi[2], Joseph J. Joseph[3], Patrick Gulinja[1], Mwaka Kakolwa[1], Kanuth Dimoso[1], Kefas Mugittu[1], Muhidin K. Mahende[1], Happiness Nyanda[4], Samwel Lazaro[2], Lulu Msangi[5], Naomi Serbantez[5], Erik Reaves[6], Francis Levira[1]

[1]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [2]National Malaria Control Programme, Ministry of Health, Dodoma, Tanzania, United Republic of, [3]AKROS, Dar es Salaam, MT, United States, [4]Health Information Systems Program, Dar es Salaam, Tanzania, United Republic of, [5]U.S. President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [6]U.S President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

Tanzania instituted the Malaria Services and Data Quality Improvement (MSDQI) supervision package for evaluation and improvement of malaria case management at the facility level. MSDQI was initially piloted between 2017–2019 and widely expanded from 2020. This quasi-experimental study evaluates the association between MSDQI and malaria-related deaths among children under five years. We used the time Jan 2017– Dec 2019 and Jan 2020–Dec 2022 to create period variables representing the time before and after the MSDQI intervention, respectively. The intervention group constituted facilities that received at least one MSDQI supervision from 2020. Facilities that never received MSDQI supervisions constituted the control group. Using a linear mixed effects model, we modeled the monthly proportion of malaria-related deaths out of all deaths in children <5 years. The primary exposure variable (MSDQI supervision) was an interaction term between period and intervention (difference in difference estimator). The model was adjusted by season at the time of death, malaria transmission strata classified from a combination of survey and routine malaria data (high, moderate, low, and very low), and residence (urban, rural, and mixed). A total of 1,804 facilities (1,088 MSDQI and 716 non-MSDQI) that reported deaths in children <5 years during the study period were included in the analysis. There was a total of 77,718 deaths, among which, 7,254 (9.3%) were attributed to malaria by a provider. Our model predicted an overall decline in the proportion of <5 malaria-related mortality from 15.1% to 9.1% in MSDQI-facilities, and from 15.4% to 11.5% in non-MSDQI facilities, representing a 2.2% reduction in mortality in MSDQI compared to non-MSDQI facilities (p-value=0.013). Facilities with three or more MSDQI supervisions demonstrated a 3.8% reduction in mortality (p-value=0.001). Malaria-related mortality in children <5 years significantly declined in all facilities, regardless of MSDQI supervision; however, reductions were greater in facilities that received MSDQI supervision, particularly for facilities that received three or more supervisions.

5508

DIVERSITY, DISTRIBUTION, AND METHODOLOGICAL CONSIDERATIONS OF HAEMOSPORIDIAN INFECTIONS AMONG GALLIFORMES IN ALASKA

Faith N. De Amaral[1], Robert E. Wilson[2], Sarah A. Sonsthagen[3], Ravinder N. Sehgal[4]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Nebraska State Museum, University of Nebraska-Lincoln, Lincoln, NE, United States, [3]U.S. Geological Survey, Nebraska Cooperative Fish and Wildlife Research Unit, University of Nebraska-Lincoln, School of Natural Resources, Lincoln, NE, United States, [4]San Francisco State University, San Francisco, CA, United States

Avian haemosporidia are globally ubiquitous blood-borne parasites, infecting a significant percentage of avian populations. Warming climates increase the viable habitat of vectors leading to range expansion, and compiling baseline data for future comparative analysis is important for predicting the long-term range of haemosporidia as range expansion of

vector populations risks exposure of naive species to infection. Using samples spanning 10-degrees of latitude in Alaska, we provide the first comparative assessment of avian haemosporidia distribution of Arctic Alaska with subarctic host populations for four species of grouse and three species of ptarmigan (Galliformes). We found a high overall prevalence for at least one haemospordian genus (88%; N=351/400), with spruce grouse (Canachites canadensis) showing the highest prevalence (100%; N=54/54). Haemoproteus and Plasmodium lineages were only observed within grouse, while Leucocytozoon species were found within both grouse and ptarmigan. Further, different Leucocytozoon lineages were obtained from blood and tissue samples from the same individual, potentially due to the differential timing and duration of blood and tissue stages. Using both Leucocytozoon and Haemoproteus/Plasmodium primer sets during PCR, we were able to identify different Leucocytozoon lineages within 55% (N=44/80) of sequenced individuals, thereby detecting coinfections that may have otherwise gone undetected. The commonly used Haemoproteus/Plasmodium primers amplified Leucocytozoon for 90% (N=103/115) of the products sequenced, highlighting the potential value of alternate primers to identify intra-genus co-infections and the importance of obtaining sequence information rather than relying solely on PCR amplification to assess parasite diversity. Overall, this dataset provides baseline information on parasite lineage distributions to assess the range expansion associated with climate change into Arctic regions and underscores methodological considerations for future studies.

GEOSPATIAL MODEL OF MOSQUITO BREEDING HABITATS AND SOME PHYSICOCHEMICAL CHARACTERISTICS IN DELTA STATE, NIGERIA

Chioma Cynthia Ojianwuna[1], **Victor Ngozi Enwemiwe**[1], Andy Ogochukwu Egwunyenga[1], Chioma Amajoh[2]

[1]Delta State University, Abraka, Nigeria, Abraka, Nigeria, [2]Community Vision Initiative (CVI), Abuja, Nigeria

Female mosquitoes are responsible for the serious disease burdens ravaging many regions of the world. Due to the limited information on geospatial model of mosquito breeding habitats and physicochemical characteristics (hereafter PCC) in Delta State, this study was designed. Six Local Government Area in Delta State, Nigeria was mapped out. Multiplex pen and GPS device were used to determine PCC and geographically map breeding habitats. Immature stages of mosquitoes were collected using 350 ml deep ladle and scooping spoons for density calculation. Breeding site characteristics was recorded using WHO template. Four hundred and sixty-six (466) breeding sites were assessed between April, 2020 and July, 2022. Mosquito density was higher in Isoko North and Okpe than in other LGAs. Geospatially, highest mosquito density was recorded in the western communities of all LGAs except Ukwani and Aniocha South. pH was slightly acidic in all LGAs except in Isoko North. Water in Ukwani and Ika North were turbid (62 and 70%), puddles (37 and 40%) and contained more of Anopheline mosquitoes whereas in other LGAs, water was clear, of diverse habitats and contained more of Anopheline mosquitoes. Waters of breeding sites were majorly of rain sources, and when both Anopheline and Culicine larvae coexist, waters were clear and of man-made source. Water temperature (To), pH, total dissolve solids and conductivity were at optimum levels. To and pH was highest in breeding sites where Anopheline and Culicine coexisted. The differences between total dissolves solids, density of mosquitoes and conductivity in the breeding sites were significant ($p< 0.05$) whereas water temperature and hydrogen concentration were not significant in breeding sites ($p> 0.05$). The implication of this results is that it can be adopted for potential vector control programs. Therefore, strengthened need is required for further studies on expanded focus and on manipulating these breeding site factors to minimize mosquito abundance.

5510

ANALYSIS OF SENTINEL SURVEILLANCE DATABASES FOR MALARIA AND ITS CLIMATIC FACTORS IN SENEGAL, FROM 2012 TO 2019

Ibrahima Mamby Keita[1], Mariama Diouf[2], Medoune Ndiop[1], Oumar Konte[2], Makhtar Sow[1], Amy Diallo[1], Yaye Mbor Samba[2], Boly Diop[1], Cheikh Mbengue[3], Samba Thioub[1], Issa Gueye[1], Samba Ndiaye[1], Abdoulaye Diatta[1], Fatoumata Ly[1], Aboubacar Diop[1], Djibril Barry[4], Khaly Gueye[1], El Hadji Mamadou Ndiaye[1], Adjaratou Diakhou Ndiaye[5]

[1]Ministry of Health and Social Action, Dakar, Senegal, [2]National Agency for Civil Aviation and Meteorology, Dakar, Senegal, [3]Ministry of the Environment and Sustainable Development, Dakar, Senegal, [4]BFELTP, Ouagadougou, Burkina Faso, [5]High Council on Global Health Security, Dakar, Senegal

Endemic in Senegal, Malaria is a climate-sensitive vector-borne disease for which sentinel surveillance notes a weakness in correlating morbidity with climatic factors data. Hence the interest in analysing malaria surveillance data and its climatic factors on a national scale through an analytical cross-sectional study (01/01/2012-31/12/2019) including predictive modelling of malaria incidence and climate data (2020-2023). It required a database integrating National Malaria Control Programme and the National Civil Aviation and Meteorological Agency data with a multi-variate analysis according to the vector autoregression. Findings showed that malaria incidence rate evolves identically from year to year following 3 phases: (i) first almost zero from January to May, (ii) then gradually increases with an accentuation in August-September, and (iii) finally decreases progressively from November to December with however a heterogeneity of the importance of the incidence (Kédougou: 12.55‰, Bakel: 7.34‰ contrary to Louga: 0.16‰). Apart from wind strength and average temperature, which evolve in opposite directions, all other climatic factors follow the same dynamics as malaria incidence, which precedes them by an average duration of 2.5 ±1 month and 1 ±0.5 month for rainfall and hygrometry respectively. The causal links found between malaria incidence and rainfall are decreasing in Dakar ($p=4.18.10-6$), Ziguinchor ($p=0.0007957$), Diourbel ($p=0.001917$), Kedougou ($p=0.004038$) and Bakel ($p=0.0332$). Other links were also observed in Bakel between incidence and the minimum ($p=0.005873$) and maximum ($p=0.01216$) temperatures. The predictive modelling shows a downward trend in malaria incidence between 2020 and 2023. This is with the exception of the sites of Dakar, Diourbel, Podor and Ziguinchor where an increase is a forecast. However, climatic factors do not follow the same trend overall. Thus the importance of synchronous (multisectoral) and integrated surveillance of malaria and its climatic factors according to the One Health approach in order to better meet the requirements of pre-elimination in Senegal.

5511

MALARIA END GAME IN WEST TIMOR: STRATEGY TO FIND AND ELIMINATE MALARIA IN LAST DISEASE POCKETS

Daniel Perlman[1], Jenny Kerrison[2], Rajitha Wickremasinghe[3], Jeffery Smith[4], Manel Yapabandara[5], Drake Zimmerman[6]

[1]MPI- Malaria Partners International, Seattle, WA, United States, [2]RAM-Rotarians Against Malaria-Australia, Melbourne, Australia, [3]Univ of Kelaniya, Kelaniya, Sri Lanka, [4]XSPI Indonesia Working Group, Kupang, Indonesia, [5]Formerly World Health Organization, Dilli, Indonesia, [6]RAM-Rotarians Against Malaria-Global, Normal, IL, United States

The National Malaria Control Program of the Republic of Indonesia is dedicated to malaria elimination by 2030. In Nusa Tenggara Timur (NTT), an area of more than 500 islands with a 5.5m population, the accelerated goal is elimination by 2028. Our presentation focus is on West Timor, with a population of 2.0m (2020) and the least favorable socio-economic status of all 33 Indonesian provinces. Several malaria strategies were adopted. The most unique was the use of community-based volunteers trained to educate and promote malaria protection, to recognize malaria signs and symptoms, and identify and refer patients experiencing fever to the community health centre. An innovative friendly competition between districts was established to accelerate sub-national malaria-free certification.

Five of 22 geographic locations are now certified malaria-free. Another novel method was adopted from the national malaria control program using the algorithm, called "1-2-5", concentrating limited resources to rapidly report the index case on Day 1, do further in-depth case surveillance and treatment on Day 2, and follow-up surveillance and management on Day 5. Currently, in West Timor, the first cohort of 23 volunteer cadres are active with ongoing training to scale up numbers. The poster presents datasets, analytics, disease burden mapping, and E-SISMAL data extracted from the NTT Province Malaria Elimination Scoping Study and Gap Analysis for Acceleration of Malaria Elimination (2022). With an API ranging from 0.08 to 1.51 cases per 1000 population, our goal of zero indigenous malaria in West Timor is not complete. Using village volunteers and the 1-2-5 algorithm must continue for malaria elimination to achieve the 2028 goal. Achieving zero malaria is critical to preventing cross-border transmission to Timor-Leste which is adjacent and malaria-free.

5512

COMPARISON OF ESTIMATES OF MALARIA TRANSMISSION INTENSITY DERIVED FROM THE FACILITY-BASED TEST POSITIVITY RATE VERSUS HOUSEHOLD, MALARIA-INDICATOR STYLE SURVEYS

Brandon D. Hollingsworth[1], Emmanuel Baguma[2], Moses Ntaro[2], Edgar Mulogo[2], Ross M. Boyce[3]

[1]Cornell University, Ithaca, NY, United States, [2]Mbarara University of Science & Technology, Mbarara, Uganda, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Measuring malaria transmission intensity using the entomological inoculation rate (EIR), while considered the reference standard, is notorious difficult. Instead, surrogate measures that are less resource intensive are frequently employed by researchers and control programs. The P. falciparum parasitemia rate (PfPR) – usually in children – is used in Malaria Indicator Surveys (MIS) and remains the most common surrogate measure of transmission intensity. Yet, household-based surveys are costly and time-consuming to perform. In addition, an MIS can only provide an estimate of malaria transmission intensity at a single point in time. By comparison, routine data derived from healthcare facilities, including test positivity or disease incidence, is relatively inexpensive and accessible. In addition, these measures can be monitored at regular intervals to providing information on how transmission may vary over time. Despite these advantages, the test positivity rate (TPR) is sensitive to issues unrelated to malaria transmission including the incidence of other febrile illness in the community. To determine if healthcare facility surveillance accurately reflects village-level malaria transmission, we compared concurrent test positivity rates (TPR) for malaria rapid diagnostic tests (RDT) to PfPR2-10 estimates from a MIS for 35 villages within the Bugoye sub-county in western Uganda. Overall PfPR2-10 in Bugoye was 5.8% overall, but varied significantly between villages, ranging from 0.0% to 31.7%. 1,869 RDTs were performed in 2-10-year-olds during the study period, with a 45.1% TPR overall, varying from 25.0% and 63.6% between villages. The relationship between PfPR2-10 and TPR was found to vary significantly between parishes and to be influenced by the distance from villages to the nearest health center. These results suggest that predicting village-level variation in malaria transmission intensity based on hospital records may be difficult without an understanding of local drivers of healthcare utilization.

5513

USING EPIDEMIOLOGICAL AND ENTOMOLOGICAL DATA TO ASSESS REMAINING EXPOSURE TO MALARIA VECTORS IN RURAL COMMUNITIES IN THE PERUVIAN AMAZON

Joaquin Gómez[1], Carlos Acosta[1], Mitchel Guzman[2], Marlon Saavedra[3], Joseph M. Vinetz[4], Dionicia Gamboa[2], Jan E. Conn[5]

[1]Laboratorio de Malaria: Parásitos y Vectores, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Laboratorio ICEMRAmazonia, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]School of Public Health, Department of Biomedical Sciences, State University of New York, Albany, NY, United States, [5]Wadsworth Center, New York State Department of Health, Albany, NY, United States

Malaria is one of the diseases with the heaviest toll on rural human populations. In 2022, more than 27 000 cases were detected in Peru, with 85% reported in the Amazonian Region of Loreto. Within Loreto, rural communities are the most affected by the disease. Hard-to-reach populations have lower accessibility to health services and are often at greater risk of malaria exposure. One of the key ways to reduce and eliminate malaria transmission is to understand the limitations of current protection levels and identify gaps that need to be addressed by national malaria control plans (NMCP). In this project, we assess the remaining exposure to malaria vectors for users of long-lasting insecticidal nets (LLIN) in three rural communities from Mazan, Loreto. We integrated entomological and epidemiological data using mathematical methods to adjust mosquito exposure by human behavior. Our analysis demonstrates marked intraseasonal variation in Ny. darlingi hourly abundance during the wet season, especially from March to May. Furthermore, communities within the Mazan watershed showed higher levels than in the Napo watershed in all months except May, when hourly abundance was similar between Libertad (Mazan w.) and Urco Mirano (Napo w.). Behavior-corrected exposure indices allowed us to determine that most of the remaining exposure occurred indoors, with a smaller proportion outdoors. However, the analysis per community revealed village-specific exposure patterns. First, Gamitanacocha (Mazan w.) had most of the remaining exposure indoors, with only 9.75% outdoors. Conversely, Libertad and Urco Mirano showed similar patterns, with around 20% outdoors and 80% indoors. Overall, we found that most of the remaining exposure to malaria vectors occurs indoors, both while awake - out of the LLIN - and while sleeping - inside LLIN. Based on our analysis, Peruvian NMCP should strengthen measures focused indoors, such as indoor residual spraying. Still, a significant amount of exposure happens outside in some communities, highlighting the need to consider the micro-heterogeneity of malaria exposure at the local level in the context of regional transmission.

5514

PUBLIC-PRIVATE PARTNERSHIP IN MALARIA CASE REPORTING IN PAPUA PROVINCE, INDONESIA: A FORMATIVE RESEARCH

Ajib Diptyanusa[1], Herdiana Hasan Basri[1], Helen Dewi Prameswari[2], Minerva Theodora[2]

[1]WHO Indonesia Country Office, Jakarta, Indonesia, [2]Ministry of Health of Republic of Indonesia, Jakarta, Indonesia

The Papua Province in Indonesia contributes approximately 90% of total malaria cases in Indonesia. However, stagnation in the progress of the malaria program has been observed since 2018, partly due to poor reporting rates from private health facilities. While some districts in Papua Province have established public-private partnership activities, the effectiveness of the partnerships may not be optimal. The current formative study aimed to identify barriers and opportunities in performing partnership practices in health facilities for tailored malaria control strategies. A qualitative study was conducted in four districts in Papua Province from October to December 2022. In-depth interviews (IDIs) and focused group discussions (FGDs) were conducted with nine target groups across the health system and community, including private practices, clinics, hospitals, private laboratories, and pharmacies. Data analysis followed the framework approach. A total of 244 participants were involved in the IDIs and 45 participants joined the FGD. In the four districts, only 101 (41.4%) health facilities have established partnerships in the malaria program. The IDIs revealed that 20% (49/244) of participants did not understand the objectives of the partnerships, and 40.5% (99/244) did not know about the process of initiating partnerships. The FGD highlighted perceived barriers to establishing partnerships, such as disparities in benefits between partners and a lack of legal documentation of the partnerships. Perceived opportunities include the willingness to initiate partnerships, particularly

in malaria case finding and management and in malaria surveillance. The current study emphasizes the engagement of private health facilities in tailoring malaria control strategies in high-endemic areas.

5515

USING LOT QUALITY ASSURANCE SAMPLING METHODS TO ASSESS COVERAGE AND QUALITY OF SEASONAL MALARIA CHEMOPREVENTION DELIVERY IN NEW GEOGRAPHIES: FINDINGS AND LESSONS FROM NORTHERN MOZAMBIQUE

Albertino Zunza

Malaria Consortium, Nampula, Mozambique

In November 2020, Malaria Consortium introduced Seasonal Malaria Chemoprevention (SMC) in, Mozambique, to evaluate its effectiveness, feasibility, and acceptability in new geographies. SMC involves administering four monthly doses of sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) during peak malaria transmission to children aged 3-59 months. Community distributors visit households monthly to reach eligible children. In January 2021, an end-of-cycle household survey was conducted evaluate SMC coverage & quality & pinpoint areas for improvement before the next cycle. In Nampula province, Mecuburi & Malema districts were surveyed using the Lot Quality Assurance Sampling method to estimate SMC coverage. 920 respondents were surveyed across 23 Health Facility Catchment Areas (HFCAs), with 13 in Mecuburi & 10 in Malema. A sample size of 40 households per HFCA (8 per settlement) was randomly selected using probability proportional to size sampling. Sixteen indicators were defined and HFCAs were classified based on whether targets were reached or not. A standardized questionnaire was administered to participants, covering SMC coverage & quality, caregivers' awareness and knowledge of SMC, & COVID-19 procedures followed by community distributors (CDs). A total of 920 people were surveyed, with 520 in Mecuburi & 400 in Malema. Results showed that 80.87% of households with eligible children were visited by community distributors (CDs) in both districts, & 85.2% of eligible children received day 1 SP+AQ. Of those, 93.7% completed the three-day course & 94.0% had their treatment directly observed by CDs. The awareness & knowledge about SMC varied between the two districts, with Mecuburi having higher rates for awareness (95.8%), knowledge of purpose (85.1%), & knowledge about managing adverse drug reactions (88.4%) compared to Malema (69.7%, 64.9%, and 69.5%, respectively). The knowledge surrounding SMC was enhanced in later cycles as we employed improved communication strategies such as radio broadcasts & health facility lectures in addition to community-based outreach.

5516

NEED TO REDUCE CLIENT WAIT TIMES DURING ANTENATAL CARE VISITS: LESSONS LEARNED FROM THE MALARIA SERVICES AND DATA QUALITY IMPROVEMENT (MSDQI) IN TANZANIA

Stella Makwaruzi[1], Goodluck Tesha[2], Saidi Mgata[1], Michael Gulaka[1], Geofrey Makenga[1], Nicodemus Govella[1], Abdallah Lusasi[3], Charlotte Eddis[4], Marguerite M. Clougherty[5], Albert Ikonje[6], Chonge Kitojo[6], Erik Reaves[7], Sigsibert Mkude[1], Samwel Lazaro[3], Lolade Oseni[8], Katherine Wolf[8]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [3]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [4]PMI Impact Malaria Project, Population Services International, Washington, DC, United States, [5]Population Services International (PSI), Washington, DC, United States, [6]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [7]U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [8]PMI Impact Malaria Project, Jhpiego, Baltimore, MD, United States

Client satisfaction with antenatal care (ANC) services has been linked to the quality of services provided and the extent to which needs are met. In Tanzania, the quality of malaria care is captured through Malaria Services and Data Quality Improvement (MSDQI) supportive supervision and includes assessment of client satisfaction. To identify parameters that might lower ANC client satisfaction, PMI Impact Malaria in collaboration with health management teams analyzed exit interview data of 939 pregnant women across 373 health facilities collected through MSDQI in Katavi, Lindi and Mtwara from 2021 to 2022. Interview questions assessed malaria testing, laboratory services, provision of and usage instructions for prescribed medicine, how to use insecticide-treated nets (ITNs), counseling for follow-up, client wait time, and health care worker (HCW) interaction with the client. The overall level of client satisfaction among the pregnant women interviewed was 89%; 98% were satisfied with malaria testing, 90% with receiving other laboratory tests, 90% for communication during HCW interactions, 87% with instructions on using medication and ITN's at home, 82% with counselling on follow-up visit, and 73% on receiving all prescribed medicine. Overall, 40% of clients waited for less than one hour, while 53% waited for 1-3 hours; 7% waited for more than 3 hours and were less satisfied with the wait time to receive services. Despite satisfaction in most of the assessed elements, further analysis is needed to understand potential reasons for longer waiting time and whether this can be reduced, as well as the nature of dissatisfaction with receiving prescribed medicine. Better understanding of drivers of client satisfaction might help to improve the quality of care delivered through ANC.

5517

IDENTIFYING REPORTING AND FOLLOW-UP CHALLENGES IN MALARIA CASE INVESTIGATION USING THE 1,3,7 STRATEGY IN A SUB-SAHARAN AFRICA PRE-ELIMINATION SETTING

Japhet M. Matoba[1], Anne C. Martin[2], Harry Hamapumbu[1], Caison Sing'anga[1], Mukuma Lubinda[1], Sydney Mweetwa[1], Ben Katowa[1], Mary E. Gebhart[3], Limonty Simubali[1], Twig Mudenda[1], Cara Wychgram[2], Amy Wesolowski[2], Matthew M. Ippolito[2], Timothy Shields[2], Andre Hackman[4], Edgar Simulundu[1], Tamaki Kobayashi[2], Douglas E. Norris[3], William J. Moss[2]

[1]Macha Research Trust, Choma, Zambia, [2]Johns Hopkins Malaria Research Institute, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Johns Hopkins Malaria Research Institute, Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The Zambia National Malaria Elimination Program recently implemented the 1,3,7 strategy in select pre-elimination districts. The strategy aims to report malaria cases within one day of diagnosis, investigate and classify them within 3 days, and respond with reactive case detection within 7 days. We conducted an implementation evaluation of an SMS-based 1,3,7 program in two health facility catchments (HFCs) in Southern Province, Zambia. Here, we report a preliminary analysis of program performance. From April 2022 to April 2023, cases were passively identified through individual case-based notification SMS messages. Cases were considered "missed-in-reporting" if they appeared on a subsequent bi-annual review of health facility registers but were not previously reported by SMS. Cases were considered "missing follow-up" if they were successfully captured by the 1,3,7 system but reactive case detection was not done. Reasons for missed reporting or follow-up were assessed qualitatively. In total, 47 cases were registered through passive case detection. Of these, 6 (13%) were missed-in-reporting, with a third missed around public holidays. Mistrust of malaria rapid diagnostic tests (e.g. suspected false positive results) was also identified as a contributing factor to missed-in-reporting in two instances. Of the 39 eligible cases, 14 (36%) were not followed up. The most common reasons for missed follow-up were index cases being outside the HFC (43%) and failure to locate the index household (14%). Four index cases residing in a densely populated boarding school setting presented a challenge for reactive case detection. Twenty-four (51%) cases were reported within 1 day while only four cases (10%) were followed within the stipulated 7 days. Testing alternate reporting mechanisms and tools for malaria case notification can help identify key implementation challenges

in adaptation of the 1,3,7 strategy to the sub-Saharan Africa context. Enhanced supervision around non-workdays and training is essential to avoid missing cases, while improved inter-HFC coordination can help ensure follow-up of cases that span HFC boundaries.

5518

RAPID ASSESSMENT OF MALARIA SURVEILLANCE SYSTEM AT DISTRICT LEVEL IN MOZAMBIQUE

Neide Canana[1], Ann-Sophie Stratil[2], Maria Rodrigues[1], Joaquim Chau[1], Antonio Bulo[1], Baltazar Candrinho[3], **Sonia Maria Enosse**[1]

[1]Malaria Consortium, Maputo, Mozambique, [2]Malaria Consortium, London, United Kingdom, [3]National Malaria Control Program Ministry of Health, Maputo, Mozambique

An assessment of the Mozambique malaria surveillance system (MSS) in 2018 identified multiple challenges preventing the system to achieve its purpose of facilitating evidence-based decision-making for malaria control and elimination. In response, Mozambique's National Malaria Control Program initiated intensive efforts to strengthen the system. The aim of the rapid assessment was to assess the status of the MSS in 2022 in relation to following parameters: performance; context and infrastructure; process; and behaviour. The assessment comprised a survey, secondary data analysis and mixed methods data collection. District Malaria Focal Points (DMFPs) from 28 districts were surveyed. Performance of the MSS in terms of completeness, timeliness and accuracy of data reporting showed In 2022, 93% (90% in 2018) of districts reported to the central database DHIS2 each month. Timeliness of data reporting increased to 89% (30% in 2018) of expected reports received on time in 2022. Precision of reporting decreased to 53% (70% in 2018). 100% of districts reported having action plans including decisions based on electronic data. Guidelines and SOPs were available in 89% of districts. 100% of DMFPs reported having access to DHIS2. 100% of districts reported having a designated technician responsible for ensuring data management of reports. 76% of DMFPs consider reporting forms easy-to-follow and 100% reported that DHIS2 was easy-to-use, however, in 25.1% of districts, a key challenge was computer availability. Overall, most respondents reported being motivated to execute data-related activities and felt districts were promoting a culture of information (70.3%). DMFP's perception to perform basic data analyses and interpretation was higher (mean 92.9%) than their self-reported capacity during testing (mean 89.6%). This assessment shows that after intensive efforts, the MSS at district level in Mozambique is useful for decision-making. However, accuracy of data remains suboptimal and infrastructure such as computers and continued training must be guaranteed for an optimal use of the system.

5519

A PROTOCOL USING SOCIAL NETWORK SAMPLING AND ANALYSIS TO QUANTIFY HUMAN MOBILITY PATTERNS AND THEIR EFFECTS ON MALARIA TRANSMISSION IN BORDER AREAS OF THE BRAZILIAN, ECUADORIAN, AND PERUVIAN AMAZON

Mark M. Janko[1], Andrea L. Araujo[2], Edson J. Ascencio[3], Gilvan R. Guedes[4], Luis E. Vasco[2], Perla G. Medrano[1], Pamela R. Chacon-Uscamaita[3], Reinaldo Santos[4], Carolina P. Coombes[3], Camila Demasceno[4], Francesco Pizzitutti[2], Gabriela Salmon-Mulanovich[5], Andres G. Lescano[3], Carlos F. Mena[2], Alisson F. Barbieri[4], William K. Pan[1]

[1]Duke University, Durham, NC, United States, [2]Universidad San Francisco de Quito, Quito, Ecuador, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Universidade Federal Minas Gerais, Belo Horizonte, Brazil, [5]Pontifica Universidad Catolica del Peru, Lima, Peru

Understanding human mobility's effects on malaria transmission is a challenge to elimination. While cell phone data are an important tool to measure mobility, coverage is sparse or non-existent in the remotest parts of the Amazon, where malaria transmission is often highest. Furthermore, cell phone data has other limitations, including the inability to identify reasons of mobility, which limits the ability of malaria control programs to tailor interventions to populations traveling for specific reasons. As a result, other approaches to measure mobility are needed in the Amazon and other remote regions. Here, we describe a social network survey protocol designed to estimate mobility patterns (magnitude, timing, duration) and their drivers across the northern Amazon spanning Brazil, Ecuador, and Peru, including across country borders. Our study uses a Respondent Drive Sampling approach with three waves of data collection. The first wave consists of 40 total initial nodes (20 spanning the Ecuador-Peru border along the Pastaza river; 20 spanning the Brazil-Peru border along the Amazon and Yavari rivers). Between four and six key informant interviews are administered in each initial node, half of whom are women. Key informants are asked about where people in their community travel to and from, the reasons for travel, the timing (e.g. season), and duration of stay. Responses are then ranked such that Wave 2 communities can be selected. Wave 2 data collection consists of interviewing key informants in 2 communities per initial node, while Wave 3 consists of conducting interviews in 2 communities per Wave 2 node. Across all waves, this design allows for 210 communities to be surveyed across the region. Results from the first wave of data collection along the Pastaza river spanning the Ecuador-Peru border indicate that each key informant survey takes only 20 minutes, and 107 unique communities were identified from the 20 initial nodes. These data will be linked to malaria surveillance and environmental data using Bayesian network autocorrelation models to estimate the effects of mobility on transmission.

5520

PLASMODIUM FALCIPARUM - P.VIVAX BIVALENT VACCINE DEVELOPMENT USING LC16M8Δ / AAV VIRAL VECTORS PLATFORM ACHIEVES STERILE PROTECTION AND TRANSMISSION BLOCKING

Yutaro Yamamoto[1], Camila Fabbri[2], Takuto Katayama[1], Tetushi Mizuno[1], Akihiko Sakamoto[1], Ammar Abdurrahman Hasyim[1], Shunsuke Okuyama[1], Sani Hadiyan Rasyid[1], Mitsuhiro Iyori[3], Hiroaki Mizukami[4], Hisatoshi Shida[5], Stefanie Costa Pinto Lopes[2], Shigeto Yoshida[1]

[1]Kanazawa University, Kanazawa city, Japan, [2]Instituto Leônidas & Maria Deane / Fiocruz Amazônia, Laboratório de Diagnóstico eControle e Doenças Infecciosas da Amazônia, Manaus, Brazil, [3]Musashino University, Tokyo, Japan, [4]Jichi Medical University, Shimono, Japan, [5]Kyoto University, Kyoto, Japan

In 2021, Malaria affected approximately 247 million cases worldwide and killed 629 thousand people. Five Plasmodium species affect humans: Plasmodium falciparum and P. vivax are responsible for approximately 99% of cases. Although P. falciparum is the deadliest, P. vivax is the most geographically spread. The problem is that P. vivax-infected areas have been expanding in recent years. Moreover, P. falciparum and P. vivax concurrent infections have been observed in several areas. There is a need for an effective vaccine against both P. falciparum and P. vivax, but no research has been done. Recently, we have developed a multistage P. falciparum vaccine based on LC16m8Δ (m8Δ)/adeno-associated virus (AAV) effective both for pre-erythrocytic (100% protection) and sexual stages (>99% transmission blocking; TB). The present study aims to apply this P. falciparum vaccine to develop a Pf/Pv bivalent vaccine with high protection levels and TB efficacy. We developed a Pf/Pv bivalent vaccine [m8Δ-Pf/Pv(s25-CSP)] harboring the fusion gene encoding the pre-erythrocytic stage antigen PvCSP and the sexual stage antigen Pvs25 into the m8Δ-Pf(s25-CSP) vaccine. Protective and TB efficacies of the heterologous m8Δ-Pf/Pv(s25-CSP) prime/AAV-Pf(s25-CSP)+Pv(s25-CSP) mix vaccine-boost immunization regimen were assessed by PfCSP- or PvCSP- transgenic (TG) sporozoite challenge and direct membrane feeding assay in a murine model. The Pf/Pv bivalent vaccine induced robust PfCSP-, PvCSP-, Pfs25- and Pvs25- specific functional IgG antibodies with a titer of more than 105 and achieved potent sterile protection up to 70% during challenge. Subsequently, when examining the TB efficacy, the vaccine regimen induced a high level of TB activity, more than 85% against P. falciparum and 98% against P.vivax. In this study, we have successfully developed a Pf-Pv bivalent vaccine based on the m8Δ/AAV viral platform

with high protective and TB efficacies. Accordingly, we are planning to evaluate the safety, immunogenicity, and vaccine efficacy in the rhesus monkey model.

5521

DELIVERY STRATEGIES FOR MALARIA VACCINATION IN AREAS WITH SEASONAL MALARIA TRANSMISSION

Jane Grant[1], Halimatou Diawara[2], Seydou Traoré[2], Fatoumata Koita[2], Jessica Myers[1], Issaka Sagara[2], Daniel Chandramohan[1], Alassane Dicko[2], Brian Greenwood[1], Jayne Webster[1]

[1]LSHTM, London, United Kingdom, [2]MRTC, Bamako, Mali

The WHO has recommended the use of the RTS,S/AS01 malaria vaccine, including seasonal vaccination, in areas with seasonal malaria transmission. No other routine childhood vaccines are currently delivered following a seasonal schedule or beyond two years of age in these countries. Therefore new approaches are required for the delivery of RTS,S/AS01 in areas with seasonal malaria transmission. This study identified the potential strategies to deliver RTS,S/AS01 in areas with seasonal malaria through a series of high level discussions with international and national immunisation and malaria experts. These strategies were then explored through in-depth interviews with malaria and immunisation programme managers, health workers, caregivers and community stakeholders in Mali, a country with highly seasonal malaria. A national level workshop was held to confirm the qualitative findings and work towards consensus on an appropriate delivery strategy for Mali. Four delivery strategies were identified: age-based vaccination delivered via the Expanded Programme on Immunization (EPI); seasonal vaccination via mass vaccination campaigns (MVCs); a combination of age-based priming vaccination delivered via EPI clinics and seasonal booster doses delivered via MVCs; and a combination of age-based priming vaccination doses and seasonal booster doses, all delivered via EPI clinics. The latter was the preferred strategy for delivery in Mali identified during the national workshop. Participants recommended that supportive interventions, including communications and mobilisation, would be needed for this strategy to achieve required coverage. These findings can be used alongside other research and practical, economic and contextual considerations, to make decisions on the delivery of RTS,S/AS01 in areas with seasonal malaria transmission. Further implementation research and evaluation is needed on these new delivery strategies, and their supportive interventions within clearly defined contexts to achieve the impressive impact achieved with seasonal vaccination in trial conditions.

INFLUENCE OF NATURALLY ACQUIRED PLASMODIUM FALCIPARUM AND SCHISTOSOMA HAEMATOBIUM INFECTIONS ON ANTIBODY RESPONSE TO FIVE MALARIA CANDIDATE VACCINES IN PREGNANT GHANAIAN WOMEN

Naa Adjeley Frempong[1], Irene Akosua Larbi[1], Atikatou Mama[2], Kwadwo Asamoah Kusi[1], Charity Ahiabor[3], Michael Fokuo Ofori[1], William Kofi Anyan[1], Bright Adu[1], Alex Yaw Debrah[4], Nicaise Tuike Ndam[5], Abraham Kwabena Anang[6], David Courtin[7]

[1]Noguchi Memorial Institute for Medical Research, Legon, Ghana, Accra, Ghana, [2]Inserm U 1016, Institut Cochin, Université de Paris 75014, Paris, France, [3]Accra Technical University, Accra, Ghana, [4]Faculty of Allied Health Sciences, Kumasi, Ghana, [5]Institut de Recherche pour le Développement & Université Paris Descartes, Paris., France, France, [6]Institute of Sanitation and Environmental Studies, Accra, Ghana, [7]Institut de Recherche pour le Développement & Université Paris Descartes, Paris., Accra, France

Women become susceptible to malaria and anaemia during pregnancy. As part of malaria elimination efforts, VAR2CSA, a Plasmodium falciparum (Pf) candidate vaccine (CV) is in clinical trial in Africa to evaluate its efficacy, while intermittent preventive treatment for malaria in pregnancy (IPTp) is administered during Antenatal Care Visits (ANC). WHO recommends Praziquantel for schistosomiasis treatment in the second trimester, but pregnant Ghanaian women are exempted from mass drug administration. In sero-epidemiological studies, antibody response to Pf CV have been associated with clinical malaria protection. However, Schistosoma haematobium (Sh) infection could modulate antibody response to CV. Our main objective was to identify factors that could influence antibody responses to five Pf CV. In all, 1153 pregnant women (ANC:707 and delivery:446) participated in a cross -sectional study in two hospitals in the Volta Region of Ghana. Pf infection was detected by microscopy and qPCR and Sh infection by microscopy. Antibody responses directed against VAR2CSA, Pfs48/45, CSP, AMA-1, GLURP-R0 were quantified by ELISA. Multivariable regression models determined underlying factors associated with antibody responses to Pf CV. Prevalence of Pf infection was 24% at ANC and 12% at delivery, 3.7% and 1.6% of women were infected with Sh respectively at ANC and delivery. Low antibody response to VAR2CSA CV [coefficient: -1.011, p=0.013] was associated with placental malaria (PM) infection when adjusted for age, insecticide treated net (ITN) and IPTp. Previous ITN use at ANC [coefficient: 0.68, p=0.02] was associated with antibody response to GLURP-R0. At delivery, IPTp was associated with decreased antibody response to GLURP-R0 VC [coefficient: -0.56, p=0.037]. Sh infection, gravidity and age was not associated with antibody response to malaria CV. We report a high PM prevalence at delivery despite the use of IPTp and ITN during pregnancy. IPTp was significantly associated with lower antibody response to GLURP-R0 VC, suggesting a lower stimulation of immune response due to parasite clearance.

5523

COMPUTATIONAL DESIGN OF A NON-GLYCOSYLATED STABILIZED PFS48/45 IMMUNOGEN ENABLES A POTENT MALARIA TRANSMISSION-BLOCKING NANOPARTICLE VACCINE

Thayne Henderson Dickey[1], Richi Gupta[1], Holly McAleese[2], Tarik Ouahes[2], Sachy Orr-Gonzalez[2], Rui Ma[1], Olga V. Muratova[2], Nichole D. Salinas[1], Jen CC Hume[2], Lynn E. Lambert[2], Patrick E. Duffy[3], Niraj H. Tolia[1]

[1]Host-Pathogen Interactions and Structural Vaccinology Section, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Vaccine Development Unit, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

A vaccine that disrupts the transmission of Plasmodium from humans to mosquitos would interrupt the parasite lifecycle and reduce morbidity and mortality within the human population. The Pfs48/45 protein is a leading antigen candidate for a transmission-blocking vaccine against P. falciparum. Domain 3 (D3) of the protein contains the most potent transmission-blocking epitopes, but production challenges have limited vaccine development. For example, a non-native N-linked glycan is required for recombinant production of D3 in eukaryotic expression systems. Here we used a computational design strategy (SPEEDesign) to create stabilized non-glycosylated Pfs48/45 immunogens that retain the potent transmission-blocking epitope. One immunogen contains seven amino acid changes from the native sequence, which result in >10 °C higher thermostability and >20-fold higher purification yields. This immunogen can be genetically fused to a nanoparticle carrier to produce a single-component vaccine that elicits potent transmission reducing antibodies in rodents at low doses. The non-glycosylated nature of this immunogen and its high production yields make it uniquely suited to diverse vaccination platforms like mRNA, recombinant protein, and viral vectors. Finally, the SPEEDesign strategy used to create this immunogen is a generalizable method that can be used to create improved vaccines targeting diverse pathogens, especially parasites with unique glycosylation patterns that are not recapitulated by recombinant expression platforms.

5524

A POTENT AND DURABLE MALARIA TRANSMISSION BLOCKING VACCINE DESIGNED FROM A SINGLE-COMPONENT 60-COPY PFS230D1 NANOPARTICLE

Nichole Salinas[1], Rui Ma[1], Thayne H. Dickey[1], Holly McAleese[1], Tarik Ouahes[1], Carole A. Long[2], Kazutoyo Miura[2], Lynn E. Lambert[1], Niraj H. Tolia[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]National Institutes of Health, Rockville, MD, United States

There were an estimated 247 million cases and 619,000 deaths worldwide due to Malaria. The majority of these deaths were children under the age of 5. With the rise in parasite resistance to antimalaria drugs, a malaria vaccine is desperately needed. Malaria vaccines can be broken down into three major classes: Pre-erythrocytic vaccines, Blood Stage vaccines, and Transmission Blocking vaccines (TBVs). TBVs function by reducing disease transmission by breaking the continuous cycle of infection between the human host and the mosquito vector, specifically by reducing the infection of the mosquito. The gametocyte surface protein Pfs230 is a leading TBV candidate. Pfs230 is a large multi-domain protein and antibodies with transmission reducing activity (TRA) map to Domain 1 (D1). Here we show that a 60-copy nanoparticle composed of the fusion of Pfs230D1 to the catalytic domain of dihydrolipoyl acetyltransferase protein (E2p) results in a single-component nanoparticle (Pfs230D1-E2p) composed of 60 copies of the fusion protein with high stability, homogeneity, and production yields. Pfs230D1-E2p also correctly presents a potent human transmission blocking conformational epitope within Pfs230D1 as shown by the ability of human mAb LMIV-01 to bind to the nanoparticle. Pfs230D1-E2p elicited a potent and durable antibody response with high TRA after two vaccinations of New Zealand White rabbits when formulated in two distinct adjuvants suitable for translation to human use (Alhydrogel and AddaS03). This single-component nanoparticle vaccine may play a key role in malaria control and has the potential to improve production pipelines and cost of manufacturing of a potent and durable TBV.

5525

EFFECTIVENESS OF A MULTI-STAGE VACCINE FORMULATION IN MALARIA VIVAX TRANSMISSION-BLOCKING

Camila Fabbri[1], Yutaro Yamamoto[2], Takuto Katayama[2], Rosa Amélia Gonçalves Santana[1], Heliana Christy Matos Belchior[1], Shigeto Yoshida[2], Stefanie Costa Pinto Lopes[1]

[1]ILMD-Fiocruz Amazônia, Manaus, Brazil, [2]Kanazawa University School of Pharmacy, Kanazawa, Japan

Outside the African continent, the predominant species causing the malaria disease is Plasmodium vivax. Given their complex live cycle, the parasite provides many potential targets for the development of vaccines, such as a transmission-blocking vaccine (TBV) which prevents the parasite development in the mosquito. This study aimed to evaluate the effect of two TBV formulation produced in an adenovirus associated virus (AAV) vector targets antigens Pvs25 and PvCSP (LC16m8Δ/AAV-Pv(s25-CSP)). This effect was evaluated through DMFA with P. vivax blood samples collected from patients diagnosed with malaria vivax and mosquitoes of Anopheles spp. from a colony of Manaus, Amazonas, Brazil. Four groups of 120-150 females were fed with P. vivax blood: control and the vaccine formulation in the 1:5, 1:10 and 1:50 dilution, in independent experiments for each type of vaccine formulation (monovalent - P. vivax - VF1; bivalent VF2 - P. vivax and P. falciparum). The mosquitoes were dissected after 7 days to calculate the transmission-blocking activity (TBA) which is calculated observing the presence of oocysts in the midgut of the treated group divided by the control group and the transmission-reducing activity (TRA) which verify the number of oocysts in the treated group also divided by the number of oocysts in the control group. After 4 isolates of P. vivax tested against the VF1, the TBA was 75.6%, 59.8% and 34.5% in the 1:5, 1:10 and 1:50 dilution, respectively. The VF2 was analyzed in five P. vivax isolates. The TBA rates 85% in the 1:5 dilution; 52.9% and 20.9% at 1:10 and 1:50 dilutions, respectively. All dilutions were also able to reduce the number of oocysts compare to the control in both vaccine formulation ($p<0.0001$), demonstrating a TRA of 95.9%, 85.0% and 78.7% in the 1:5, 1:10 and 1:50 VF1 dilutions, respectively; 98.9%, 94.1% and 66.8% in the 1:5, 1:10 and 1:50 VF2 dilutions, respectively. The 1:5 and 1:10 dilutions demonstrated high TBA and TRA in both VF. Based in these results it is possible to initiate preclinical studies using rhesus monkeys to confirm the efficacy and safety of these vaccine formulations.

BIOINFORMATIC APPROACH TO DESIGN A PLASMODIUM FALCIPARUM PFRIPR MULTI-EPITOPE VACCINE CONSTRUCT

Alexander John Laurenson, Emily Stucke, Ryan Scalsky, Matthew B. Laurens

University of Maryland School of Medicine, Baltimore, MD, United States

Malaria infections remain an enormous contributor to global fatalities with an estimated death toll of 619,000 in 2021 and 77% of deaths being children aged under 5 years. Transmitted via mosquito, Plasmodium falciparum is the most lethal parasite of its genus but has evaded many treatment and vaccine efforts due to its complex life cycle and redundant invasion mechanisms. Epitope-based vaccines hold significant promise for malaria vaccine development due to their ease of development and ability to target dominant regions in antigenically variable pathogens. The recently characterized protein P. falciparum merozoite Rh5 interacting protein (PfRipr) is nonredundant, highly conserved, and essential for erythrocyte invasion, making it an ideal target for a bloodstage malaria vaccine. Using P. falciparum sequences collected from Burkina Faso and Uganda, we assessed the immunogenic potential of PfRipr epitopes with regard to T-cell receptor binding and B-cell recognition. T-cell receptor binding was predicted using NetMHCpan searching against MHC I and II alleles with high regional frequencies. Using an in-silico 3D model of PfRipr predicted via AlphaFold, tertiary structures of all PfRipr sample sequences were predicted via SWISS-MODEL then analyzed by ElliPro to identify linear and discontinuous B-cell epitopes. Putative epitopes were filtered using allele coverage, conservation, antigenicity, and allergenicity. Between the two datasets, there were 19 matching epitopes with 7 MHC I, 9 MHC II, 1 linear, and 2 discontinuous. These epitopes were used to design a multi-epitope-based bloodstage vaccine construct against P. falciparum. To validate their predicted immunogenicity, epitopes can be further investigated using in silico protein stabilization and docking simulations, in vitro methods such as HLA stabilization or T-cell activation assays, and in vivo methods using transgenic mouse models. The pipeline of immunoinformatic analyses formulated in this project can be further applied to P. falciparum sequence datasets collected from other malaria endemic regions to develop vaccines effective against circulating strains.

HUMORAL IMMUNE RESPONSES TO THE CENTRAL REPEAT REGION OF PFCSP INDUCED BY A VIAL-VECTORED PLASMODIUM FALCIPARUM VACCINE PLAY CRITICAL ROLES IN PROTECTION IN A MURINE MODEL

Shunsuke Okuyama[1], Yutaro Yamamoto[1], Shunsuke Murai[1], Mitsuhiro Iyori[2], Tetsushi Mizuno[3], Akihiko Sakamoto[1], Shinya Fukumoto[4], Hiroaki Mizukami[5], Hisatoshi Shida[6], Shigeto Yoshida[1]

[1]Laboratory of vaccinology and Applied Immunology, Kanazawa University School of Pharmacy, Kanazawa city, Japan, [2]Department of Pharmaceutical Sciences, Musashino University, Tokyo, Japan, [3]Grobal Infectious Disease Graduate School of Medical sciences, Kanazawa city, Japan, [4]Obihiro University of Agriculture and Veterinary Medicine, Hokkaido, Japan, [5]Division of Gene Therapy, Jichi Medical University, Shimono, Tochigi, Japan, [6]Laboratory of Primate Model, Research Center for Infectious Diseases, Institute for Frontier Life and Medical Science, Kyoto University, Kyoto, Japan

We have previously constructed a viral-vectored vaccine platform consisting of the attenuated replication-competent vaccinia virus strain LC16m8Δ

(m8Δ) and adeno-associated virus (AAV). A heterologous m8Δ-prime and AAV-boost immunization regimen (m8Δ/AAV) provided 100% protection in a murine model. The aim of this study is to elucidate the vaccine protection mechanism using mutated parasites. It is widely recognized that a successful pre-erythrocytic malaria vaccine should induce not only humoral immune responses but also CD8+ T-cell-mediated immune responses to inhibit the infection of the liver by sporozoites and to eliminate any resulting liver-stage parasites that develop in hepatocytes. Our previous study showed that recombinant human adenovirus type 5 (AdHu5)/AAV harboring the pfcsp gene induced robust CD8+ T-cell-mediated immune responses, but partially protected mice against sporozoite challenge (60%). A fundamental question is why the m8Δ/AAV is more effective than the AdHu5/AAV with the same pfcsp antigen gene. To investigate the vaccine mechanism, we generated two lines of transgenic parasites based on PfCSP/Pb parasite; deletion of H-2Kd-restricted T-cell epitope of PfCSP (PfCSPΔCD8/Pb), replacement of NANP-repeat region of PfCSP with the corresponding region of PvCSP (PfCSP-Pv repeat/Pb). The m8Δ/AAV vaccine provided 80% and 20% protection against PfCSPΔCD8/Pb and PfCSP-Pv repeat/Pb, respectively. These results suggest that the central repeat region of PfCSP plays critical roles in protection, which is consistent with the data that the immune sera have high levels of anti-sporozoite neutralizing activity, as evaluated in vitro sporozoite neutralizing assay. In the mouse model, protection of our vaccine is mainly due to humoral rather than cellular immunity. In the previous study, the CSP-specific antibodies and CD4+ T-cell responses induced by vaccination with RTS,S/AS01 have been correlated with protection in clinical trials. We are generating a new parasite that is deficient in CD4 epitope to further evaluate the vaccine mechanism.

DETERMINANTS OF VACCINE COVERAGE AND ACCEPTABILITY OF MALARIA VACCINE IN CHILDREN AGES 6-23 MONTHS IN MALAWI: A HEALTHCARE PROVIDER'S PERSPECTIVE

Dumisile Sibongile Nkosi

Training and Research Unit of Excellence, Blantyre, Malawi

Developing appropriate interventions for immunisation in young children requires a detailed understanding of immunisation levels and factors affecting coverage among children. Although there has been an increase in the overall coverage of DPT3 from 84% to 94% between 2016 and 2020, only 78% of the 28 districts in Malawi achieved the targeted coverage of greater than 80% in 2020. This indicates that there is still a gap in childhood vaccine coverage within the country. Additionally, understanding the acceptability of a vaccine before rollout helps in generating appropriate interventions to improve vaccine coverage. The main objective of this research project was to evaluate the determinants of vaccination coverage and acceptability of the RTSS malaria vaccine in children aged 6-23 months in Malawi. A systematic review of 12 full-text articles was conducted using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses framework to identify research articles that address the acceptability and coverage of vaccines in young children in Malawi. Secondly, a qualitative study design using purposive sampling of 20 healthcare workers at the Zomba District Health Office was conducted. Data were collected using in-depth telephonic interviews. Qualitative data were analysed using thematic content analysis to establish themes related to factors that affect the coverage and acceptability of the malaria vaccine. Vaccine coverage and acceptability were affected by: limited transportation, limited immunisation training for healthcare providers, socioeconomic status of the caretaker, education of the mother, community knowledge of the vaccine, trust in the health system, male gender's influence on health decisions, the load and coherence of healthcare workers and caregivers, and the perceived malaria burden and effectiveness of the vaccine. Health promotion efforts on increased immunization service resources, and healthcare worker training for immunization services can contribute to addressing low vaccine coverage and acceptance.

5529

VACCINE-INDUCED PFRH5 HUMAN MONOCLONAL ANTIBODIES SHOW BROADLY NEUTRALIZING ACTIVITY AGAINST PLASMODIUM FALCIPARUM CLINICAL ISOLATES

Laty Gaye Thiam[1], Kirsty McHugh[2], Aboubacar Ba[1], Rebecca Li[3], Mariama Nicole Pouye[1], Dimitra Pipini[2], Fatoumata Diallo[1], Seynabou Diouf Sene[1], Alassane Thiam[1], Bacary Djilocalisse Sadio[4], Alassane Mbengue[1], Simon J. Draper[2], Amy Kristine Bei[3]

[1]G4 Malaria Experimental Genetics Approaches and Vaccines, Institut Pasteur de Dakar, Dakar, Senegal, [2]Department of Biochemistry, University of Oxford, UK, Oxford, United Kingdom, [3]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [4]Virology Unit, Institut Pasteur de Dakar, Dakar, Senegal

Blood-stage malaria vaccines target the pathogenic phase of the malaria parasite life-cycle, therefore preventing the disease progression upon infection of the erythrocytes by merozoites following the primary liver-stage infection. The Plasmodium falciparum reticulocyte binding-like protein homologue 5 (PfRH5) is increasingly moving towards being the lead blood-stage malaria vaccine candidate, with recent promising clinical trial outcomes. As malaria vaccine development has for long been hampered by the extensive genetic diversity of naturally circulating parasites, we performed ex-vivo growth inhibition assays (GIA) to assess the inhibitory potential of vaccine-derived monoclonal antibodies (mAbs) to PfRH5 in P. falciparum clinical isolates. Our data reiterate previous reports on invasion inhibition by both vaccine-induced antibodies to PfRH5 and to the receptor basigin. We observed a dose-dependent inhibition of the parasite invasion across all vaccine-induced mAbs, with three main GIA groups, high, medium and low. Overall, while no significant difference was observed in the antibody susceptibility levels between the clinical isolates and the control lines, there was a lower susceptibility in clinical isolates across all dilutions for the most potent mAb (R5.016). Surprisingly, we observed a moderate inhibition levels with R5.011 (median = 50.14%) and R5.001 (median = 41.64%), previously reported to be lowly-inhibitory in isolation. Furthermore, we also observed the earlier reported synergistic effect of R5.011 when the later was combined with the least inhibitory mAbs used in this study, namely R5.001, R5.007 or R5.008. Ongoing analyses consisting of targeted amplicon deep sequencing of PfRh5 will permit genotype-phenotype association studies for antibodies with variation in inhibitory levels (R5.016). Data from the ongoing analyses will be presented at the conference.

5530

SUPERIOR FUNCTIONAL ANTIBODY ACTIVITY OF A DELAYED-BOOST VACCINATION REGIMEN WITH THE PLASMODIUM FALCIPARUM BLOOD-STAGE VACCINE RH5.1/MATRIX-MTM IN 5-17 MONTH OLD TANZANIAN INFANTS

Jo Salkeld*[1], Sarah E. Silk*[1], Wilmina F. Kalinga*[2], Ivanny M. Mtaka[2], Catherine Mkindi[1], Florence Milando[2], Neema Balige[2], Saumu Ahmed[1], Jordan R. Barrett[1], Kazutoyo Miura[3], Ababacar Diouf[3], Jenny Reimer[4], Cecilia Carnrot[4], Fay L. Nugent[1], Carole A. Long[3], Rachel Roberts[1], Jee-Sun Cho[1], Alison M. Lawrie[1], Carolyn M. Nielsen[1], Simon J. Draper*[1], Angela M. Minassian*[1], Ally Olotu*[2]

[1]University of Oxford, Oxford, United Kingdom, [2]Ifakara Health Institute, Bagamoyo, Tanzania, United Republic of, [3]National Institute of Health, Rockville, MD, United States, [4]Novavax AB, Uppsala, Sweden

Plasmodium falciparum (Pf) reticulocyte binding protein homologue 5 (RH5) is the leading blood stage malaria vaccine candidate antigen. Non human primate vaccine studies have established the in vitro growth inhibition activity (GIA) as a correlate of protection against blood stage Pf challenge; defined as a threshold of GIA>60% at 2.5mg/mL purified total IgG. However RH5 vaccines have not previously consistently reached this threshold in humans. Vaccine induced GIA was higher using RH5 protein in adjuvant vaccines than viral vectored vaccines and in Tanzanian infants compared to UK adults. A delayed fractional (DFx) regimen of RH5 protein in adjuvant was also more immunogenic than a monthly regimen in UK

adults. We further assessed dose and regimen in 12 adults and 48 infants (age 5-17 months) vaccinated with soluble protein RH5.1 in Matrix-M (MM) adjuvant in a Phase Ib age de-escalation trial in Tanzania. Adults were vaccinated in 2 regimens: monthly (0-1-2 months, 10-10-10µg RH5.1) and DFx (0-1-6 months, 50-50-10µg RH5.1). Infants were vaccinated in 3 regimens: monthly, DFx and delayed (0-1-6 months, 10-10-10µg). A fourth infant group with high prior malaria exposure was vaccinated in a DFx regimen. Vaccines were given in 50µg MM. Vaccinations were well tolerated with no safety concerns. The most commonly reported adverse events (AEs) were injection site swelling and subjective fever. Solicited AEs were generally mild-moderate and all spontaneously resolved within a few days. As expected humoral immunogenicity was higher in infants than in adults. The average peak GIA in all infant groups exceeded the target 60% threshold with no impact of prior malaria exposure. Importantly, the delayed infant group showed the highest overall GIA, with each infant exceeding the target GIA. The delayed regimen also showed significantly higher serum anti-RH5 IgG at 10 months post final vaccination. These data suggest the importance of delayed rather than DFx dosing for RH5.1/MM in 5-17 month old infants. This delayed RH5.1/MM dosing regimen will now progress to a Phase IIb trial in 5-17 month old infants in Burkina Faso to assess efficacy against clinical malaria.

5531

STRUCTURES OF VAR2CSA WITH HOST RECEPTOR REVEALS TARGETABLE INTERFACES FOR NEXT GENERATION PLACENTAL MALARIA VACCINE DESIGN

Rui Ma, Tengfei Lian, Nichole D. Salinas, Rick Huang, Jonathan P. Renn, Thayne H. Dickey, Jennifer Petersen, Joshua Zimmerberg, Sachy Orr-Gonzalez, Brandi Richardson, Tarik Ouahes, Holly Torano, Bethany J. Jenkins, Justin Y.A. Doritchamou, Lynn E. Lambert, Patrick E. Duffy, Niraj H. Tolia

National Institute of Health, Bethesda, MD, United States

Placental malaria is caused by the accumulation of Plasmodium falciparum parasites in the placenta, resulting in poor pregnancy outcomes including mortality for mothers and their offspring. Parasite sequestration is mediated by binding of the parasite protein VAR2CSA to its receptor chondroitin sulfate A (CSA) on the surface of the syncytiotrophoblast. VAR2CSA is a 350 kDa polymorphic multi-domain protein of the PfEMP1 variant surface antigen family, and the leading vaccine candidate to prevent placental malaria. We determined atomic-resolution structures of the full-length P. falciparum ectodomain of VAR2CSA from strain NF54 in complex with CSA, and VAR2CSA from strain FCR3 by cryo-electron microscopy. This study provides the structural definition for a full-length PfEMP-1 family member. Six Duffy-binding-like (DBL) domains and two Interdomain (ID) regions interact in an interwoven manner to stabilize VAR2CSA. The structures resemble the number 7 with a stable core flanked by a flexible arm. CSA traverses the core domain by binding within channels in the core. The CSA-binding elements are conserved across VAR2CSA variants and are flanked by polymorphic segments, suggesting immune selection outside CSA-binding sites. Receptor-free and receptor-bound VAR2CSA are structurally similar, indicating no major domain rearrangement is required to bind CSA. Structure-guided design leveraging the full-length structures of VAR2CSA produced a stable immunogen that retains the critical conserved functional elements of VAR2CSA. The novel VAR2CSA vaccine construct is expressed at much higher levels than the full-length protein and elicited antibodies that prevent adherence of infected erythrocytes to CSA. This design forms a strong foundation for the development of potent strain-transcending placental malaria vaccines.

THE INNOVATIONS IN MALARIA VACCINE DEVELOPMENT PROGRAM (IMV)

Evangelos Simeonidis[1], Jenifer Haner[1], Jessica Harkhani[1], Emily Locke[1], Trevor Lutzenhiser[1], Randall MacGill[1], Heather Richards[1], Yimin Wu[1], Susan Youll[2], Robin Miller[2], Lorraine Soisson[2], Simon J. Draper[3], C. Richter King[1], Ashley Birkett[1]

[1]PATH, Seattle, WA, United States, [2]United States Agency for International Development (USAID), Washington, DC, United States, [3]University of Oxford, Oxford, United Kingdom

The Innovations in Malaria Vaccine Development contract (IMV) is funded by the US Agency for International Development (USAID) and implemented by PATH. The IMV is designed to solve key underlying challenges in the preclinical development and clinical evaluation of next-generation malaria vaccines. It consists of three Workstreams: the circumsporozoite protein (CS) workstream, the blood stage (BS) workstream focused on RH5 and other antigens in the RH5 complex, and the combination (CS+BS) workstream. A common core strategy of all the IMV projects is to build on existing data to identify and advance next-generation vaccine candidates, inducing a more potent and durable immune response that interferes with critical steps in the parasite life cycle—namely, the initial infection of hepatocytes and the progression of asexual BS infection leading to clinical disease. By focusing on the potency of immune responses, the IMV is aiming to increase the durability of protection of future vaccines—an important limitation of the first-generation vaccine, RTS,S/AS01 (RTS,S). In partnership with an international consortium inclusive of the University of Oxford, Statens Serum Institut, Scripps Research, Walter Reed Army Institute of Research, Johns Hopkins University, the University of Texas at Austin, and others, the IMV continues to make significant progress in all three workstreams. Recent advances include establishing RTS,S as a benchmark in an advanced preclinical model of malaria infection, which is available for comparison testing of novel CS-based vaccine candidates. Other advances include development of an improved quantitation method of CS antibody responses across all regions of the molecule. Most recently, the IMV has advanced a next-generation particalized RH5-based BS vaccine candidate to Phase 1 clinical trial. Here, we will present an overview of the above and other key accomplishments, platform areas of interest (such as mRNA-LNP), lessons learned, and future directions.

5533

TRENDS IN THE PREVALENCE AND COMMUNITY KNOWLEDGE AND PRACTICES WITH REGARDS TO PROBABLE TYPHOID FEVER IN SANTA HEALTH DISTRICT - CAMEROON

Pensha Joysline

Georgetown Center for Global Heath,, Yaounde, Cameroon

This study aimed at determining the trend in the prevalence, risk factors and community knowledge and practices regarding probable typhoid fever in Santa Health District. Two study designs were used: A retrospective study design which laboratory hospital records (2014 to 2018) were reviewed to determine the trend in probable typhoid fever and a cross-sectional community-based study design to assess the knowledge and practices regarding probable typhoid fever (TF) in 250 households. Data was collected using laboratory data review sheets and structured questionnaire respectively for the two study designs. Data was entered in excel and Epi-Info version 7.2 statistical software which were later exported to SPSS Version 25 for analysis. Chi-square test of independence was used to determine relationship between risk factors of typhoid fever and logistic regression was used to adjust for confounders. Level of significance was set at P-value < 0.005. The results showed that the prevalence of typhoid fever varied significantly ($\chi 2 = 202.73$; $P = 0.0001$) over the study period with the year 2016 recording the highest prevalence of 2016 (24.4%) and the least prevalence 511 (6.2%) was recorded in the year 2015. Of the 250 participants enrolled in the KAP study, 60% of the respondents reported that at least one member of their household had suffered from TF

episode once, while 62% of the respondents were aware of TF disease, 57.2% of respondent knew its control methods but poor practices (hand washing with soap). We therefore conclude that there was a linear trend in the prevalence of typhoid fever across the year 2014 to 2018 with a general increase in prevalence. The level of knowledge of TF was high (62%) with poor practices toward typhoid fever prevention. Also, socio-demographic factors had no influence on the high typhoid fever prevalence (60%) reported by the participants. Based on these results, we recommend intensive health education and prevention programs targeting this community to increase preventive practices and decrease incidence, prevalence, morbidity, and mortality due to poor preventive measures on typhoid fever and other enteric diseases.

5534

CHOLERA OUTBREAK IN SPECIAL INSTITUTIONS MACHAKOS COUNTY, KENYA, 2022

Serah Nairuko Nchoko

Field Epidemiology and laboratory Program, Nairobi, Kenya

Kenya experienced widespread cholera outbreaks in 1997-1999 and 2007-2010. The re-emergence of cholera in Kenya in 2022 indicates that cholera remains a public health threat. Understanding the risk factors is important for preventing future outbreaks. This study aimed to identify risk factors for the cholera outbreak in Machakos school for the deaf and Machakos main prison during the time period Oct 2022-Nov 2022. This was a cross-sectional study carried out in Machakos county. Outpatient (OPD) and laboratory registers were reviewed from Oct 2022 through Nov 2022 as well as active case search was conducted. Data were abstracted and a line list was developed. Descriptive and analytical statistics were conducted. Multivariate analysis was conducted to identify independent factors associated with cholera. A total of 214 clinically suspected cases of cholera and 3 deaths were reported (overall case-fatality rate [CFR], (1.4%), over 75.5% (161/214) of the cases recorded were from the age group below 20yr majority being male 54.2% (116/214). Most positive cases were reported from the prison department 54.2% (19/35) and from the age group between 21-30 17% (6/35). Vibrio cholerae O1, serotype Ogawa, was the predominant isolated strain. The Attack rate in prison was 4.4% (40/900) and in school for the deaf 46.5% (174/374). One had 7 times the odds of being a case with the disease for not washing hands before eating OR 7.5 95% CI(1.27-44.08) P-0.02.There was a confirmed cholera outbreak affecting both institutions access to clean water is necessary for the prevention of cholera infection. institution to treat water refilled by tankers before consumption and Machakos county to intensify efforts to expand access to improved sanitation facilities and clean drinking water.

SEROPREVALENCE OF VIBRIO CHOLERAE IN HAITI, 2017

Wilfredo R. Matias[1], Yodeline Guillaume[1], Gertrude Cene Augustin[2], Kenia Vissieres[2], Ralph Ternier[2], Richelle C. Charles[1], Jason B. Harris[1], Molly F. Franke[3], Louise C. Ivers[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]Zanmi Lasante, Port-au-Prince, Haiti, [3]Havard Medical School, Boston, MA, United States

In Haiti and areas combating cholera epidemics where disease surveillance capacity is limited, case counts often fail to accurately estimate the true burden of cholera. In 2017, we conducted a seroepidemiologic survey of cholera in Cerca-la-Source and Mirebalais, Haiti to estimate disease prevalence and identify risk factors for seropositivity during the waning phase of the first Haitian cholera epidemic. We collected dried blood spot samples on filter paper from adults and measured serum vibriocidal antibody titers against Vibrio cholerae O1. A serum Ogawa or Inaba vibriocidal antibody titer of ≥ 320 was considered seropositive. We used a raking procedure to apply survey weights based on the population distribution of age, gender, and communal sections from a census, and a random intercept to account for clustering by household. We used logistic regression to test for associations between potential risk factors and seropositivity. We enrolled 99 households with 156 individuals in Cerca-la-Source and 118 households with 121 individuals in Mirebalais. The prevalence of serum vibriocidal antibody titers was 12.4% (95%CI 6.76 - 20.0) in Cerca La Source and 9.54% (95%CI 4.91 - 16.0) in Mirebalais. Prevalence of the Ogawa serotype was 9.73% (95%CI 5.38 - 16.0) in Cerca-la-Source and 8.75% (4.28 - 15.0) in Mirebalais, which was higher than the prevalence of the Inaba serotype in Cerca-la-Source (2.69%, 95%CI 0.49 - 8.00) and Mirebalais (2.73%, 95%CI 0.57 - 7.00). There was a moderate association between poverty and seropositivity (OR 2.33, 95% CI 0.93 - 5.84, P = 0.07). There was no association between self-reported cholera or diarrhea and seropositivity. These seroprevalence estimates from 2017 suggest a high recent burden of infection during the waning phase of the first Haitian cholera epidemic. Improved epidemic disease surveillance programs to monitor cholera and guide public health interventions in Haiti are necessary.

EFFICACY OF TYPHOID CONJUGATE VACCINE AGAINST CULTURE-CONFIRMED SALMONELLA TYPHI - A SYSTEMATIC REVIEW AND META-ANALYSIS

Rabab Batool[1], Rehanan Abdus Salam[2], Zoya Qamar Haq[3], Farah Naz Qamar[1]

[1]Aga Khan University Hospital, Karachi, Pakistan, [2]University of Sydney, Sydney, Australia, [3]Liaqat National Hospital, Karachi, Pakistan

After the emergence of extensively drug-resistant strains, Typhoid has become a serious public health threat in many low- and middle-income countries. World Health Organization has recommended a new typhoid conjugate vaccine as the control strategy in typhoid-endemic countries. We performed a systematic review and meta-analysis to estimate the vaccine efficacy (VE) of the typhoid conjugate vaccine against culture-confirmed Salmonella Typhi. A systematic literature search was conducted in electronic databases including Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, and Embase up to 5 January 2023. Randomized control trials comparing the efficacy of typhoid conjugate vaccine with control were eligible for inclusion. Two reviewers independently screened, extracted data and assessed the risk of bias of included studies. Certainty of evidence for key outcome was evaluated using the GRADE methodology. The outcome of interest was typhoid fever confirmed by the isolation of Salmonella enterica serovar Typhi in blood. We calculated pooled risk ratios (RRs) and VE (1 – RR as a percentage) with associated 95% confidence intervals. Four RCTs contributed to the quantitative analysis in this review, including 111509 (mean 27877) participants. All of the trials were conducted in typhoid-endemic countries, trial participants ages ranged from 6 months to 16 years. Overall VE of a single shot of typhoid conjugate vaccines against culture-confirmed S. Typhi at 2 years post-immunization was 83% (95% Confidence Interval (CI): 77%, 87%). We also conducted subgroup analysis by age group. Compared with control, TCV has demonstrated greater efficacy among children aged > 5 years to 16 years, VE: 87% (95% CI: 80%, 91%) in this age group as compared to the younger children aged 6 months to 5 years, VE: 73 % (95% CI: 53%, 85%). The existing data from included trials provides promising results on the efficacy of TCV in typhoid-endemic countries. Future research on the long-term efficacy of conjugate vaccines and their impact on enteric infection and shedding is warranted.

5537

FECAL PH AS A MARKER OF CHRONIC MALNUTRITION OR STUNTING AMONG CHILDREN HOSPITALIZED FOR DIARRHEA AND OTHER NON-DIARRHEAL PATHOLOGIES

Md. Shabab Hossain

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Fecal pH is a simple, non-invasive and inexpensive diagnostic tool used for initial screening of certain gastrointestinal diseases. Elevated fecal pH indicates reduction of beneficial microbiota in gut, especially Bifidobacteria

and commensal Clostridia, which has emerged as a key factor contributing to chronic malnutrition or stunting. Bifidobacteria and Clostridia clusters XIVa and IV are considered as important gut symbionts in infants and abundance of these in the gut is indicative of optimum linear growth. These microbiota contribute to formation of acidic feces by producing short chain fatty acids (SCFAs) as a byproduct of their fermentation process, which is acidic in nature and have a significant effect on fecal pH. Thus an elevated fecal pH passively denotes to decrease of these microflora in the gut. The purpose of this cross-sectional study was to investigate the association of fecal pH with stunting in hospitalized children and was conducted on 200 children aged 06-24 months getting admitted in icddr,b Dhaka Hospital with diarrhea and Dhaka Shishu Hospital for other non-diarrheal pathologies. Length-for-age Z scores (LAZ) was measured and data on factors affecting linear growth was recorded. Fecal pH was measured on freshly collected stool samples. Multivariate linear regression analysis was performed to explore relationship between fecal pH and LAZ scores. The mean fecal pH of diarrheal and non-diarrheal children was 5.54±0.98 and 5.95±0.76, respectively. Pearson correlation between fecal pH and LAZ scores of non-diarrheal children showed a statistically significant inverse correlation (-0.21, p<0.01) and a similar trend was also observed in scatter plot. After inclusion of factors affecting linear growth into the regression model, a statistically significant inverse association between fecal pH and LAZ scores was observed in non-diarrheal children (p<0.01). Elevated fecal pH in non-diarrheal children was found to have significant association with stunted growth, making fecal pH a possible indirect determinant of childhood stunting. However, such associations did not apply for diarrheal children.

5538

IMMUNOGENICITY AND TOLERABILITY OF DIFFERENT DOSE SCHEDULES OF TYPHOID CONJUGATE VACCINE IN NEPAL

Sanjeev M. Bijukchhe[1], Meeru Gurung[2], Bhishma Pokhrel[2], Mila Shakya[3], Dikshya Pant[3], Merryn Voysey[1], Yama F. Mujadidi[1], Young Kim[1], Sarah Kelly[1], Buddha Basnyat[3], Andrew J. Pollard[1], Shrijana Shrestha[2]

[1]University of Oxford, Oxford, United Kingdom, [2]Patan Academy of Health Sciences, Kathmandu, Nepal, [3]Oxford University Clinical Research Unit, Kathmandu, Nepal

Previously, the Vi-typhoid conjugate vaccination (Vi-TT) was found to be efficacious in Nepalese children under 16 years of age. In the current study we assessed the immunogenicity of Vi-TT (Typbar TCV, Bharat Biotech International, India) at 9 and 12 months of age and after a booster dose at 15 months, at Patan Hospital, Kathmandu. Fifty participants each were recruited in the 9- and 12-month groups. Seroconversion (4-fold rise in IgG antibody titre) was 100% in both groups. Post-booster, the 9-month group showed significantly higher IgG seroconversion than the 12-month group. Several study visits occurred outside protocol windows due to COVID19 pandemic. All participants who attended visits per protocol (n=27 in the 9-month and n=32 in the 12-month groups) showed IgG seroconversion following the first dose. However, after the second dose, seroconversion rates were 80% in the 9-month group and 0% in the 12-month group (p<0.001). Vi-TT is immunogenic at both 9 and 12 months of age. The longer interval between doses in the 9-month group was associated with a stronger response to a booster.

DIARRHEA EPIDEMICS IN DHAKA, BANGLADESH BEFORE AND DURING THE COVID-19 PANDEMIC: AN EPIDEMIOLOGICAL INVESTIGATION

S. M. Tafsir Hasan, Baharul Alam, ASG Faruque, Tahmeed Ahmed

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Moderate to large diarrhea epidemics are commonplace in Bangladesh. However, it remains to be investigated whether the characteristics of diarrhea epidemics changed in the context of the COVID-19 pandemic. This study examined the attributes of patients presented to a specialized diarrheal disease hospital (icddr,b Hospital) in Dhaka, Bangladesh during two recent diarrhea epidemics in Dhaka and its neighboring areas: one occurring in 2022, amidst the pandemic, and another in 2018, immediately preceding the pandemic. We identified the duration of epidemics objectively as the period when daily patient visits exceeded the 90th percentile of daily visits in the last two epidemic-free years before the pandemic (2017 and 2019). Dhaka Hospital treated 29212 and 59971 diarrheal patients during the 2018 (April 2 - May 12) and 2022 (March 6 - May 1) epidemics, respectively. Compared to 2018, individuals presenting during the 2022 epidemic were more frequently children under five years (37.0% vs 26.3%, p < 0.001), and less frequently drank tap water (52.8% vs 77.8%, p < 0.001) and belonged to a family with a monthly income less than USD100 (5.9% vs 13.0%, p < 0.001). Vibrio cholerae was the most common enteric pathogen, with a comparable isolation rate between the two periods (28.4% in 2022, 27.2% in 2018, p = 0.632). The detection rate was also comparable for enterotoxigenic Escherichia coli (12.3% vs 14.2%, p = 0.283), Campylobacter (10.5% vs 13.2%, p = 0.111), and rotavirus (8.6% vs 7.8%, p = 0.603). Of the V. cholerae isolates, 98.7% belonged to the O1 serogroup and El Tor biotype. The Inaba (71.8%) and Ogawa (67.3%) serotypes predominated in 2022 and 2018, respectively. Of the patients, 98.8% presented with watery stools and 85.9% with vomiting. While the patients presented less frequently with some dehydration during the pandemic (17.8% vs 28.8%, p < 0.001), the proportion of severe dehydration was comparable (51.7% vs 53.6%, p = 0.474). The in-hospital case fatality rates were low in both periods (0.05% vs 0.04%, p = 0.580). V. cholerae served as the primary agent in both diarrhea epidemics, with a serotype shift from Ogawa to Inaba during the pandemic.

5540

RISK FACTORS FOR SYMPTOMATIC AND ASYMPTOMATIC INFECTION WITH DIARRHEAGENIC E. COLI IN INFANTS OF PERI-URBAN LIMA, PERU

Lucie Ecker[1], Claudio F. Lanata[1], Ana I. Gil[1], Theresa J. Ochoa[2]

[1]Instituto de Investigación Nutricional, Lima, Peru, [2]Department of Pediatrics, School of Medicine, Universidad Peruana Cayetano Heredia, Lima, Peru

Diarrheagenic E. coli (DEC) are responsible for around 30 to 40% of diarrheal episodes in children less than five years of age. Only few and pathotype specific studies describe factors associated to symptomatic and asymptomatic infection with DEC. We aimed to determine the factors associated with symptomatic and asymptomatic infection with DEC and persistent diarrhea in children under one year of age, in peri urban areas of Lima, Perú. The database of a passive diarrhea comunity-based surveillance study of 1034 Peruvian infants followed from 2 to 12 months of age was retrospectively analyzed. We used random effects model regression to assess associated factors. Overcrowding (OR: 1.5, p=0.007, 95% CI: 1.12-2.11) and storing water in medium-sized containers (up to 10L) (OR: 1.6, p=0.024, 95% CI: 1.06-2.45) increased the risk of DEC infection and having started complementary feeding doubled the risk of DEC infection (OR: 2.0, p=0.003, 95% CI: 1.27-3.30). Children who had started feeding, had more diarrhea due to DEC (OR: 2.7, p<0.000, 95% CI: 1.55-4.58) and higher risk of EPEC (OR: 3.5, p=0.001, 95% CI: 1.64-7.5) and EAEC (OR:1.9, p=0.019, 95% CI: 1.11-3.31) symptomatic and asymptomatic infection. Males had more diarrhea due to DEC (OR: 1.5, p=0.015, 95% CI: 1.09-2.12) and for each additional month of age, the risk decreased (OR:0.9, p=0.009, 95% CI: 0.88-0.97). EAEC as a single pathogen doubled the risk of persistent diarrhea (OR: 2.5, p=0.023, 95% CI: 1.14-5.6). We concluded that there is a greater risk of infection with DEC in overcrowded homes and in those who stored water inmedium-sized containers and in male children who have started complementary feeding. The risk decreased with age. These pathogens should be routinely looked for in young children, especially EAEC which was associated with persistent diarrhea.

5541

FACTORS ASSOCIATED WITH PERSISTENCE OF STUNTING AT THE END OF THE FOLLOW-UP PERIOD AMONG BANGLADESHI CHILDREN WITH DIARRHEA

Md. Tanveer Faruk, Md Farhad Kabir, Irin Parvin, Abu Sadat Mohammad Sayeem Bin Shahid, Rumana Sharmin, Deena Sultana, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Stunting, a form of malnutrition, characterized by impaired linear growth in the first two years of life, affects one child out of four globally. The prevalence of stunting in Bangladesh is also high. However, we don`t have adequate information about the burden and ramification of persistence of stunting. Thus, the primary aim of this study was to determine the factors associated for persistence of stunting. We performed a secondary analysis of data collected in the 'Antibiotics for Childhood with Severe Diarrhea (ABCD)' trial. For the purposes of this study, children aged 2-23 months who had complete records for height, weight, age, and sex were selected. We have compared between two groups of children: one group had stunting during enrolment and recovered on day-90 follow up and other group was enrolled with stunting and that persisted up to day-90 follow up period (cases). We expressed weight and height as z-scores. Children with height-for-age-z-score <-2 categorized as stunted according to WHO guidelines. Out of 1431 children, 589 were enrolled with stunting (z score < - 2) and 542 remained stunted on day-90 post-discharge follow-up. Thus, the number of cases was 542 and control was 877. The cases more often presented with lack of vaccination following EPI schedule, had illiterate mothers, and were less often partially or exclusively breastfeed on day-90 post-discharge follow up compared to those who didn`t have persistent stunting (for all, $p < 0.05$). Therefore, the study results underscore the importance of continuation of vaccination following EPI schedule, breast feeding up to 2 years of age, and parental education that may help to reduce the burden of persistent stunting and their consequence.

5542

COMPARATIVE CHARACTERISTICS OF CHILDREN HOSPITALIZED FOR ACUTE, CHRONIC AND WITHOUT MALNUTRITION

Abu Sayem Mirza MD Hasibur Rahman, MD Ahshanul Haque, Sharika Nuzhat, MD Farhad Kabir, Fardaus Ara Begum, Tahmeed Ahmed, Mohammod Jobayer Chisti

International Centre for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

The application of clinical and laboratory methods revealed diverse findings among children hospitalized for acute, chronic and without malnutrition. However, their comparative data are limited to under 5 children. Data were extracted from the electronic data system of the Dhaka Hospital of icddr,b from 2019–2021. Among 1881 children under the age of 5, 177 children, 239 children and 652 children were eligible for the acute malnutrition, chronic malnutrition and well-nourished groups, respectively. We compared these children separately. Among 1068 children, 889 (83%) had diarrhea. The prevalence of acute and chronic malnutrition in diarrheal children was, respectively, 14% and 17%. After adjusting for age and sex in the multiple regression model, hyponatremia (Na <135 mmol/L) was found to be significantly higher [aOR = 2.33 (95% CI: 1.50, 3.61); p<0.001] and raised creatinine was significantly lower [aOR = 0.52 (95% CI: 0.30, 0.90); p=0.020] in acute malnourished children. Both anemia (Hb <11.5 gm/dl) and thrombocytosis (Platelet >400 x 109/L) were significantly prevailing in chronic malnutrition cases [aOR = 2.21 (95% CI: 1.60, 3.07); p<0.001 and aOR = 2.44 (95% CI: 1.78, 3.33); p<0.001]. Children with acute and chronic forms of malnutrition were more often observed non-breastfed [aOR = 2.32 (95% CI: 1.60, 3.38); p<0.001 vs. aOR = 2.10 (95% CI: 1.46, 3.02); p<0.001] than well-nourished children. The incidence of hypernatremia was substantially lower in children who were acutely and chronically malnourished (both p<0.050) compared to well-nourished children. Thus, the children hospitalized for acute, chronic and without malnutrition need to be identified separately for their appropriate management framework.

5543

FACTORS ASSOCIATED WITH MORTALITY IN SEVERELY MALNOURISHED HOSPITALIZED CHILDREN WITH DIARRHOEA WHO DEVELOPED SEPTIC SHOCK

Mehnaz Kamal, Visnu Pritom Chowdhury, Monira Sarmin, Shafiul Islam, Farzana Afroze, Tahmeed Ahmed, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Septic shock can often lead to death, even in resourceful settings, if not handled carefully. Therefore, we sought to evaluate the factors associated with deaths in the context of severe malnutrition and also the effects of early, i.e., within 3 hours of diagnosing septic shock vs. late blood transfusion. In this retrospective chart analysis, we first prepared a case-record forms (CRFs) and collected relevant patient data from a digital patient management system at icddr,b hospital. Out of 276,523 under-five children admitted to this diarrhoeal hospital with the complaint of diarrhoea from the year 2013 to 2017. Patients are shifted to intensive care unit (ICU) immediately when they developed critical complications - such as respiratory distress, severe pneumonia with hypoxemia or respiratory failure, repeated hypoglycemia, severe sepsis, septic shock, altered level of consciousness. We found 93 severely malnourished children developed septic shock and received the blood transfusion at the ICU. Participants who aged between 2 to 59 months of age and of either sex were enrolled. Children who died constituted cases (n = 54), and the survived (n = 39) represented controls. We excluded children who received the blood transfusion for other causes and who left against medical advice. In both descriptive and multivariate analysis, we found that death was significantly associated with the requirement of fourth-line antibiotics (Meropenem plus Vancomycin), corticosteroids, and the addition of vasopressors on top of dopamine (all $p < 0.05$). However, the decrease of total serum calcium level (<2.12 mmol/L) was found significantly associated with death only after adjusting ($p < 0.05$). Even though the cases more often received early blood transfusion than the controls, the difference was insignificant ($p = 0.134$). When a severely malnourished under-five child develops septic shock, requiring vasopressors, fourth-line antibiotics, and corticosteroid, with reduced serum calcium, the probability of death increases significantly. Our findings underscore the gravity of close monitoring at these points and the niches for early interventions.

5544

ISOLATION AND WHOLE GENOME SEQUENCING OF A CRONOBACTER SAKAZAKII SEQUENCE TYPE 136 STRAIN, FROM READY-TO-EAT FOOD

Irshad M. Sulaiman, Nancy Miranda, Steven Simpson, Kevin Karem

U. S. Food and Drug Administration, Atlanta, GA, United States

Cronobacter sakazakii is an emerging, infectious, Gram-negative, bacterium that can survive in extreme arid environments. This opportunistic pathogen is known to cause acute meningitis and necrotizing enterocolitis in neonates, elderly, and immunocompromised individuals. It has been linked primarily to contaminate powdered infant formula (PIF) and for causing PIF-related sporadic cases and foodborne outbreaks worldwide. Nevertheless, it has also been recovered from a wide range of foods. Molecular characterization studies have revealed a high level of species-level genetic polymorphism, encompassing unique clonal complexes and sequence types, frequently associated with foodborne illness and outbreaks. Currently, application of whole genome sequencing (WGS) has advanced bacterial typing and is widely utilized for precise strain identification to understand disease transmission. In this study, a C. sakazakii-like Gram-negative bacterial isolate SRL-72, from ready-to-eat

food prepared in the Southeast Asian region, was recovered and analyzed. Initial microbial identification was accomplished on VITEK 2, RT-PCR, and MALDI-TOF MS based analysis, following FDA's Bacteriological Analytical Manual and manufacturer's recommended protocols. WGS was completed on an Illumina MiSeq system, using a Nextera XT DNA library preparation kit and a 250-bp paired-end read MiSeq Reagent *v2* kit (500-cycle), following manufacturer's instructions. MALDI-TOF MS identified the C. sakazakii SRL-72 isolate as C. sakazakii with a high confidence value (99.9%). WGS analysis revealed the genome sequence of C. sakazakii isolate SRL-72 was 4,501,682 bp in length and distributed in 66 contigs Analysis further confirmed the genome of C. sakazakii isolate SRL-72 to be Sequence Type 136 for . C. sakazakii ST136 has been considered to be a highly stable clone with a high propensity to cause neonatal meningitis. Therefore, MALDI-TOF MS and WGS methods can be applied for rapid and precise identification of human-pathogenic C. sakazakii isolates of public health importance.

TITANIUM DIOXIDE NANOPARTICLES CAN ACTIVATE HUMAN DENDRITIC CELLS AGAINST MYCOBACTERIUM LEPRAE INFECTION: A PROMISE FOR DENDRITIC CELL IMMUNOTHERAPY AGAINST LEPROMATOUS LEPROSY

Jorge Cervantes

Texas Tech University Health Sciences Center Paul L. Foster School of Medicine, El Paso, TX, United States

Leprosy is a chronic infectious disease caused by Mycobacterium leprae, which is still endemic in many parts of the world including Southern Texas. The two polar clinical forms of leprosy, termed tuberculoid and lepromatous, have polarized cellular immune responses, with complex immunological distinctions. Dendritic cells (DCs) are the primary antigen presenting cells in the immune system. TiO2 nanoparticles have shown to induce maturation of these cells leading to an inflammatory response. We aimed to evaluate the effect of potassium incorporated TiO2 nanostructures, KTiOx, in the response of human monocyte-derived-DCs to M. leprae. THP-1 human monocytes were differentiated and maturated into DCs using commercially available media, and then treated with KTiOx for 24 hours. Following, cells were infected with M. leprae at an MOI of 10:1 for 24 hours. Activation of transcription factor NF-kB and IRF was assessed through reporter plasmid systems. Secreted human cytokines were measured in the culture supernatants by a multiplex ELISA system. We observed that KTiOx nanoparticles increased DC phagocytic activity without activation of inflammatory transcription factor NF-kB. An increase in the levels of secreted IFN-α and TNF-β upon M. leprae infection in cells treated with KTiOx was also detected. IFN-β and its downstream gene IL-10 are preferentially expressed in disseminated and progressive lepromatous lesions, while the TNF-β gene is identified as a major risk factor for early-onset leprosy. It is possible that this wider KTiOx area can activate more DCs due to an increase in the contact area. This study demonstrates the effect of nanostructures of KTiOx in the in vitro activation and modulation of human DCs against an infectious disease with a puzzling immune spectrum. Our findings may prompt future therapeutic strategies such as DC immunotherapy for disseminated and progressive lepromatous lesions.

5546

CHARACTERIZATION OF MULTIDRUG-RESISTANT ESKAPE PATHOGENS ISOLATED FROM A PUBLIC HOSPITAL IN HONDURAS IN 2021

Faviola A. Reyes Quan[1], Melissa Montoya[1], Patricia Perez[2], Marco Moncada[2], Paul Rios[3], Silvia Zelaya[2], Tyler Moeller[3]

[1]Naval Medical Research Unit 6, Comayagua, Honduras, [2]Hospital Escuela Universitario, Tegucigalpa, Honduras, [3]Naval Medical Research Unit 6, Lima, Peru

The ESKAPE group of bacterial pathogens (Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, and Enterobacter spp.) pose a global public health threat, commonly causing multidrug-resistant (MDR) nosocomial infections. A cross-sectional surveillance study was performed to identify antimicrobial resistance patterns for ESKAPE isolates collected from Hospital Escuela Universitario in Honduras in 2021. A total of 169 ESKAPE isolates were included for identification and antimicrobial susceptibility testing following the Clinical and Laboratory Standards Institute M100 guidelines. Vancomycin-resistant Enterococcus (VRE), methicillin-resistant S. aureus (MRSA), extended-spectrum β-lactamase (ESBL)-producing bacteria, and carbapenem-resistant (CR) pathogens were detected by the disk-diffusion test, E-test method, and minimum inhibitory concentration method by BD Phoenix M50. The majority of bacterial strains were isolated from skin and soft tissue secretions (44.4%), blood (29.6%) or body fluids (10.7%). The frequency among the ESKAPE isolates examined was K. pneumoniae 43.8%, A. baumannii 40.2%, P. aeruginosa 8.9%, E. faecium 3.0%, S. aureus 2.4%, and Enterobacter spp. 1.8%. Overall, 90.5% of the pathogens were MDR, including 100% of K. pneumoniae and A. baumannii isolates. ESBL-producing K. pneumoniae and Enterobacter spp. were detected in 12.2% and 33.3% of cases, respectively. A high prevalence of CR A. baumannii (100%) and P. aeruginosa (26.7%) was observed. No MRSA or VRE was observed among isolates. ESKAPE pathogens isolated from Hospital Escuela Universitario in Honduras demonstrated substantially high rates of MDR. ESBL and CR pathogens were frequently isolated from nosocomial infections. Antimicrobial surveillance targeting nosocomial MDR pathogens should be a high priority for the hospital infection control policy. Optimizing transmission control measures and antibiotic stewardship is advised for the adequate prescription of antibiotics to reduce selective pressure conducive to MDR.

5547

EPIDEMIOLOGY OF STAPHYLOCOCCUS AUREUS PATHOGENS CAUSING INVASIVE DISEASE IN PATIENTS SEEN AT MRC CLINIC, FAJARA THE GAMBIA

Mamadou Mballow, Henry Badji

MRCG at LSHTM, Banjul, Gambia

Staphylococcus aureus is a major cause of both community and hospital-acquired infections around the world and one of the leading causes of infection in The Gambia particularly in children. Little is known about the genetic diversity of strains circulating in the country especially those causing invasive disease. We describe the epidemiology of S. aureus causing invasive disease in The Gambia. 134 invasive isolates obtained from clinical samples of patients seen at the MRC clinic in Fajara, The Gambia between 2014 and 2020 were analyzed in this study. Multilocus Sequence Typing (MLST) was used to characterize S. aureus strains. Antimicrobial susceptibility was determined using the Kirby-Bauer disc diffusion technique. Invasive S. aureus infection was more common in males (52%) while the highest number of isolates was obtained from children &lt 2 years. Blood specimens accounted for 81% of the isolates. Antibiotic susceptibility patterns strains were 6%, 87%, 51%, 97%, 98%, 93%, 97%, and 96% for penicillin, trimethoprim-sulphamethoxazole, tetracycline, chloramphenicol, gentamicin, erythromycin, cloxacillin and methicillin respectively. Difference in susceptibility to trimethoprim-sulphamethoxazole between the different age groups was statistically significant (P=0.030). A statistically significant difference between Methicillin-Susceptible Staphylococcus aureus (MSSA) and Methicillin-Resistant Staphylococcus aureus (MRSA) in susceptibility to penicillin, gentamicin and cloxacillin was also statistically significant. MLST identified 19 Sequence Types. Our study provides essential information on invasive S. aureus strains in The Gambia. Invasive S. aureus infections can be successfully treated with widely available antibiotics in the country. Discovery of MRSA strains calls for more care and continuous surveillance for early detection of changes in susceptibility patterns. There is need for closer monitoring of the genetic diversity and clonal dissemination of strains present in the country particularly those causing diseases for future consideration in vaccine adoption.

5548

SURVEILLANCE OF COLISTIN RESISTANCE PREVALENCE OF NOSOCOMIAL ORIGIN IN PERU

Jesus D. Rojas[1], Paul A. Rios[2], Enrique A. Canal[2], Manuela M. Bernal[2], Rina A. Meza[2], Tyler D. Moeller[2]

[1]Vysnova Partners Inc., Reston, VA, United States, [2]U.S. Naval Medical Research Unit No. 6, Lima, Peru

Studying colistin resistance in nosocomial settings is crucial due to the growing threat of multidrug-resistant (MDR) Gram-negative bacterial infections. Low- to middle-income countries (LMIC) are particularly vulnerable to colistin resistance and understanding its epidemiology and risk factors can inform effective public health policies and interventions to combat antimicrobial resistance. A surveillance study conducted in Lima, Peru, collected 3703 bacterial isolates between January 2018 and October 2022. Clinical isolates were refrigerated and transported to the U.S. Naval Medical Research Unit No. 6 for identification and antimicrobial susceptibility testing. Bacterial isolates were identified using the MALDI-TOF Bruker and BD Phoenix automated system and tested for susceptibility using the Kirby-Bauer method and/or Phoenix. Colistin susceptibility testing (CST) was also conducted, and PCR was used to identify the mcr-1 gene associated with colistin resistance. Clinical and Laboratory Standards Institute 2022 guidelines were used for antimicrobial susceptibility testing (AST) interpretation. The most prevalent microorganisms subjected to CST were: Klebsiella pneumoniae (n=502), Pseudomonas aeruginosa (n=484), and Acinetobacter baumannii (n=203). AST revealed that over 85% (n=427) of K. pneumoniae, 83% (n=402) of P. aeruginosa and 96% (n=195) of A. baumannii were resistant to at least 2 different antibiotic families. CST analysis showed that 10% of K. pneumoniae were resistant to colistin, and 10% of those carried the mcr-1 gene. In addition, 5% (n=10) of A. baumannii and 3% (n=16) of P. aeruginosa isolates were resistant to colistin, and, interestingly, none carried the mcr-1 gene. Our findings demonstrate high levels of MDR among isolates, with observed resistance to colistin varying from 3 to 10%. Continuous surveillance of antimicrobial resistance to multiple classes of antibiotics is paramount in the nosocomial setting, with heightened importance in regions where antimicrobial treatment options are limited and colistin is an antibiotic of last resort.

5549

THE LEPTOSPIRAL PROTEIN LIC12254 INTERACTS TO INTEGRINS VIA THE RGD MOTIF

Maria F. Cavenague, Aline F. Teixeira, Luis G. Fernandes, **Ana L. Nascimento**

Instituto Butantan, Sao Paulo, Brazil

Leptospirosis is a zoonosis globally disseminated caused by pathogenic spirochetes of the genus Leptospira. Understanding leptospiral pathogenic mechanisms is critical for the efficient development of vaccines and diagnostic tests. Outer membrane proteins are considered potential antigens could mediate interactions with host components, such as integrins, that are involved in cell regulation, proliferation, adhesion and immune response. The leptospiral RGD protein encoded by gene lic12254 was selected for study. In silico analysis was investigated by LipoP, Interprot and CELLO web servers. Protein conservation analysis in different strains of Leptospira was performed by BLASTp and a 3D model was assessed by I-TASSER and analyzed by PyMOL. The recombinant proteins LIC12254 and LIC12254ΔRAA (RGD mutated) were cloned in pAE vector and expressed in E. coli strains. The evaluation of interaction of LIC12254 protein via RGD motif to human integrins was evaluated by ELISA. In silico analysis showed that protein LIC12254 is probably located on the outer membrane and has two conserved domains, Omp85 and DUF5982. 3D models showed a beta barrel structure and protein conservation analysis identified a high sequence similarity among pathogenic strains. In addition, the RGD is present only in pathogenic species. The motif RGD in LIC12254 protein sequence was replaced by PCR techniques and genes lic12254 and lic12254ΔRAA were cloned successfully into the protein expression pAE vector and recombinant proteins were obtained from insoluble form. Recombinant proteins were observed in the expected size of 54 kDa by SDS-PAGE and confirmed by western blot. The evaluation of interaction of LIC12254 protein to human integrins showed that rLIC12254 was capable to interact with αVβ8 and α8 integrins in a dose-dependent manner. As expected, the interaction with rLIC12254ΔRAA was inhibited. Our results described rLIC12254 outer membrane protein capable of interact to human integrins via RGD motif. Thus, rLIC12254 could be involved in bacterial pathogenesis by adhesion process.

5550

CHARACTERIZATION OF ANTIGENIC SITES OF NEISSERIA GONORRHOAE USING HIGH-DENSITY PEPTIDE MICROARRAYS AND PSORALEN-INACTIVATED, WHOLE-CELL VACCINE IN MICE

Michael E. DeWitt[1], Leigh Ann Sanders[1], Appavu K. Sundaram[2], Maria Blevins[1], Kevin R. Porter[2], John W. Sanders[1]

[1]Wake Forest University School of Medicine, Winston-Salem, NC, United States, [2]U.S. Naval Medical Research Center, Bethesda, MD, United States

Neisseria gonorrhoeae infections are an urgent public health threat with over 100 million cases reported globally each year. The threat of N. gonorrhoaea, a sexually transmitted infection, has been further exasperated by the increase in drug resistant strains including against last line antibiotics necessitating the need for an effective vaccine. Vaccine development has been challenging due to a lack of clearly identified antigenic targets, a high degree of strain variability, and immune evasive mechanisms of the bacteria itself. Recent retrospective studies have indicated that vaccination against N. meningitidis, a closely related bacteria also of the Neisseria genus, using the protein-based meningococcal group B vaccine (4CMenB) may provide modest effectiveness of 23-53% against infection with N. gonorrhoaea—though the effect appeared short-lived. Further studies have sought to characterize cross-reactivity of different antigenic sites which may explain this protection. To assess different vaccine approaches to both known and unknown cross-reactive antigens we vaccinated mice with two different vaccines both with and without the mucosal adjuvant, dmLT. In the first case we utilized whole-cell, formalin inactivated N. gonorrhoaea (FA1090). In the second case Psoralen plus ultraviolet A light (PUVA) was used to create killed but metabolically active (KMBA) whole-cell vaccine. Antibody profiles were screened from four mouse serum pools using high-density peptide microarrays using proteins covering pre-selected membrane and intracellular proteins, where higher intensities indicated higher reactivity. We observed reactivity in all vaccines against 15 previously published antigenic sites in the 4CMenB vaccine. Further, we see reactivity equal to or greater than the suspected cross-reactive proteins against additional sites including other intracellular proteins and outer-surface membranes. These findings suggest that a multi-epitope vaccine can be developed using a PUVA-generated KBMA whole cell approach. Additional study is needed in mapping of possible epitopes for N. gonorrhoaea vaccine development.

5551

ORAL CHOLERA VACCINATION CAMPAIGN COVERAGE SURVEY IN GARISSA, WAJIR, TANA RIVER, AND NAIROBI COUNTIES, KENYA

Cynthia Atieno Musumba[1], Mark Matheka[1], Stephen Olublyera[1], Maurice Mowiny[1], Fredrick Odhiambo[1], Ahmed Abade[1], Maria Nunga[1], Caren Ndeta[1], Hilary Limo[2], Catherine Kiama[3]

[1]Kenya Field Epidemiology and Laboratory Training Program, Nairobi, Kenya, [2]Ministry Of Health Kenya,Emergency Operations Center, Nairobi, Kenya, [3]Washington State University, Nairobi, Kenya

Kenya confirmed cholera outbreaks on October 19, 2022. The outbreak progressed to 17 counties Garissa and Tana River Counties had the highest attack rates of Cholera at 239.1& 231.1/100,000 population. Kenya conducted its first-ever Oral cholera vaccination campaign in February 2023, in Garissa, Wajir, Tana River and Nairobi. The survey assessed Cholera vaccination coverage, Risk communication strategies, knowledge attitude and practices on cholera and water sanitation and

hygiene practices related to cholera. A household-based survey was conducted, targeting persons aged one year and above. WHO formula for calculating immunization coverage was used to calculate the households to be interviewed.Multi-stage proportionate-to-size cluster sampling strategy was used to determine the number of clusters and randomly selected 7 households per cluster. Data was collected using a standard questionnaire. Data was analyzed for continuous and categorical variables. A total of 122 clusters, and 858 households were visited with 5456 eligible participants. Of the 861 households targeted 99.7% (858/861) were interviewed. Coverage at individual level was 93.2% (2640/2834). Majority of the females 58.8%(1553/2640) were vaccinated. Those aged 6-14 years were the most vaccinated 26.9%(709/2640). Of those vaccinated, 7.7%(202/2640) experienced adverse events.A good number of the respondents were aware of the Oral Cholera vaccination campaign 90.2% (774/858) and 98.6% (846/858) said that those sick should seek treatment in Health facilities. Those who did not treat their drinking water were 62.6% (537/858) and 10.7% (92/858) lacked latrines. Water scarcity was also an issue with 51% (438/858) reporting not having water in the last month. The vaccine coverage was within the acceptable range to provide prevention and stop infection transmission. However, there is need to strengthen Water, Sanitation and Hygiene interventions across all the counties in addition to oral cholera vaccine in order to control cholera and reduce deaths.

5552

LABORATORY EVALUATION OF THE IS2404 LAMP TEST FOR LABORATORY DIAGNOSIS OF BURULI ULCER DISEASE

Roberta Dedei Afi Tackie, Anthony Ablordey, Patience Adams, Joseph Bonney, Jennifer Amedior
Noguchi Memorial Institute for Medical Research, Accra, Ghana

Buruli ulcer, caused by Mycobacterium ulcerans has emerged as an important public health problem in several rural communities in sub-Saharan Africa. Early diagnosis and prompt treatment are important in preventing disfiguring complications associated with the late stages of the disease progression. Presently there is no simple and rapid test that is appropriate for early diagnosis and use in low-resource settings where M. ulcerans is most prevalent. The study aimed to evaluate the use of crude DNA extract and the IS2404 LAMP test for rapid diagnosis of Buruli ulcer. We evaluated the LAMP method for detecting M. ulcerans in clinical specimens by investigating its performance with IS2404 PCR, a reference assay for detecting M. ulcerans. The effect of using crude and purified DNA extracts on the performance of the IS2404 LAMP test was also investigated. Seventy-five clinical samples from suspected BU cases were examined by LAMP and IS2404 PCR. A total of 49 positive samples were concordantly detected by both the LAMP and PCR tests. Additional two positive samples were detected by IS2404 PCR for which the IS2404 LAMP tests were negative. Also, both methods concordantly scored 24 samples as negative for Buruli ulcer while the LAMP assay discordantly scored two additional negative results. Taking the PCR results as a reference, the sensitivity and specificity of the LAMP test were 96.1% and 100% respectively. The lower detection limit of both the IS2404 LAMP and IS2404 PCR tests was 30 copies of IS2404. Nine of 30 samples were positive by both the IS2404 LAMP and IS2404 PCR when crude extracts of clinical specimens were used. Thus, the diagnostic sensitivity of the IS2404 LAMP test decreased with the use of crude DNA extract. In conclusion, the IS2404 LAMP test performed on purified DNA extracts d can be used as a simple and rapid test for the diagnosis of Buruli ulcer.

5553

PHENOTYPIC CARBAPENEMASE DETECTION ADAPTED FOR RESOURCE CONSTRAINED SETTINGS

Ali Asghar Haider, Alex Page, Sarah Satola, Jesse J. Waggoner
Emory University, Atlanta, GA, United States

WHO has estimated that by 2050 as many as 10 million people will die annually due to antimicrobial resistance. Carbapenems are broad-spectrum antibiotics often used as a last line of defense for resistant gram-negative bacterial infections. Resistance to carbapenems from transmissible carbapenemase enzymes is on the rise, though the scale of this issue in many locations remains unclear due to high costs and complexity of current testing methods. We modified the Carba NP phenotypic assay to quickly and economically differentiate the three classes of carbapenemases. Varied antibiotic concentrations, indicator solutions, and reaction volumes were evaluated in an iterative manner to adapt existing 'Carba NP test II' chemistry to a low-volume, plate-based format to objectively measure absorbance on various plate readers. Reaction speed and capacity to differentiate KPC, NDM, and OXA-48 enzymes (class A, B and D enzymes, respectively) were evaluated to optimize detection at ambient temperature, without dedicated incubation at 37°C. Changes in absorption at 560nm in the phenol-red-imipenem indicator solution were consistently observed before visible color change. Compared to the Carba NP version II, reliable results were obtained at ambient temperature with 3mg/mL of imipenem (vs. 6 mg/mL), 2 µL of bacteria (vs. 20µL), reaction volumes of 40µL (vs. 130 µL), and in 15 minutes (vs 2 hours). Three patients at Emory University Hospital with carbapenem-resistant gram-negative bacterial infections had positive cultures tested using the modified assay. All patients were found to have Class A (e.g., KPC) carbapenemase-producing bacteria within 15 minutes. In one patient, the emergence of a carbapenemase-producing bacteria while on systemic antibiotic therapy was observed. The modified Carba NP developed in this study is a rapid and economical method to screen for carbapenemases and is adaptable for use in resource constrained areas to inform clinical care and mitigate transmission in healthcare settings. Furthermore, the platform could be adapted to detect resistance to other key antibiotics, such as ceftriaxone resistant Salmonella typhi.

5554

MOLECULAR CHARACTERIZATION OF EXTENDED SPECTRUM BETA-LACTAMASES (ESBLS) -PRODUCING KLEBSIELLA PNEUMONIAE AND ESCHERICHIA COLI ISOLATES FROM THE WESTERN REGIONAL HOSPITAL IN GHANA

Patience Lartekai Adams, Jennifer Amedior, Roberta Tackie, Anthony Ablordey
Noguchi Memorial Institute for Medical Research, Accra, Ghana

Extended spectrum beta-lactamases (ESBLs) are plasmid-mediated enzymes that hydrolyze beta-lactams except carbapenems and cephamycins but are inhibited by beta-lactamase inhibitors. Majority of ESBL plasmids also contain genes that confer resistance to a variety of non-beta-lactam antimicrobials. As a result, ESBL-producing isolates limit therapeutic options, contribute to treatment failure, increase morbidity and mortality, prolong hospitalization, and raise healthcare costs. This study determined antimicrobial resistance profiles and the presence of antibiotic resistance genes in K. pneumoniae and E. coli isolates from the Western Regional Hospital in Ghana. A total of 120 archived isolates recovered from blood, urine, wound, pleural aspirate, high vaginal, ear, and urethral swabs were used in the study. The Kirby Bauer agar disc diffusion method was used to determine the antimicrobial susceptibility profiles of the isolates. Multidrug-resistant strains were phenotypically screened for ESBL production by the double disc synergy test. All isolates with ESBL phenotypes were screened for blaTEM, blaSHV, and blaCTX-M genes by PCR. Very high resistance was observed for ampicillin (78.4%), cefazolin (59.3%), SXT (56.5%) and tetracycline (56.3%). Fairly high resistance was observed for nalidixic acid (46.4%), chloramphenicol (45.4%), cefpodixime (43.2%) and Cefuroxime (42.4%). Very low resistance was observed for imipenem (2.4%), doripenem (4.1%) and cefepime (4.2%) based on the CLSI inhibition zone size interpretation criteria (CLSI, 2012). Forty-two (34.7%) of the 120 isolates phenotypically expressed ESBLs. Of these, 33 (27.9%) were pure ESBLs and 8 (6.8%) were putative ESBL producers. Overall, 62.7% (n=69/110) of the ESBL genotypes expressed CTX-M types 1, 2 and 9 genes and followed by 60% (n=24/40) harbored in TEM (n=7), SHV (n=5), and OXA-1 (n=12) genes. The study showed a relatively high

level of ESBL-producing isolates at the Regional Hospital, largely the CTX-M type and underscores the need to routinely detect ESBL phenotypes and implement appropriate antimicrobial stewardship policies in health facilities.

IN SITU GROWTH OF ZIF-67 ON HALLOYSITE NANOTUBES EMBEDDED IN CHITOSAN HYDROGEL FOR THERAPEUTICS IN PARASITIC INFECTIONS

Swetha Shanmugam, **Amutha Santhanam**
University of Madras, Chennai, India

Reconstruction for major bone defects caused by trauma, tumors and other diseases is a persistent clinical challenge. A successful bone treatment must take into account a number of factors, including the stability of the materials, stable microenvironments, an ample blood supply, and sufficient osteogenic activity. Finding biomaterials is thus required to assist the surgery to be completed. As a potential tactic, hydrogels could offer an internal environment with adequate moisture, comparable to natural extracellular matrices (ECMs). In this study, we synthesize a novel kind of nanocomposite hydrogel film by growing ZIF-67 nanoparticles in-situ on halloysite nanotubes (HNTs), which were then combined with chitosan matrix for biomedical application. Then, FT-IR, UV-DRS, XRD, and HRSEM were used to characterize the synthesized materials. Halloysite nanotubes added to hydrogel significantly improved its thermal and mechanical properties. Gram-positive and gram-negative bacteria were used to test the antimicrobial effectiveness of hydrogel, and the results showed that hydrogel film had maintained its strong antibacterial activity. The haemolysis assay demonstrated the haemocompatibility of the fabricated hydrogel film. Based on the research, it was concluded that fabricated hydrogel film could be applied for biomedical application.

5556

ADHERENCE AND ACCEPTANCE OF ORAL AMOXICILLIN DISPERSIBLE TABLET FOR THE TREATMENT OF SICK CHILDREN IN KARACHI, PAKISTAN

Kiran Ramzan Ali Lalani
The Aga Khan University Hospital, Karachi, Pakistan

World Health Organization's Integrated Management of Childhood Illnesses (IMCI) guidelines suggest the use of amoxicillin for treatment of young infants with signs of Possible Serious Bacterial Infection (PSBI) where referral is not possible and for treatment of pneumonia in young infants and children. The suspension form of amoxicillin has been widely used for years; however, dispersible tablets (DT), a more user-friendly form of amoxicillin has been introduced in recent years. Experience from countries like Pakistan show mixed acceptance of DT formulation however adherence have been found to be better than oral suspension. In a cohort study of 535 caregivers presenting to primary healthcare centers in peri-urban Karachi, Pakistan children aged up to 5 years old were prescribed DT of Amoxicillin. Data was collected on day 8 of treatment with Amoxicillin DT. Frequencies and percentages are reported for responses. Mean age was 25 months (SD 18 months), indications included lower respiratory tract, ear and skin infections etc. At the time of prescription, 509 (98%) of mothers had never used dispersible tablets but 344 (69%) mothers thought that babies younger than 6month can easily be given DT. Post treatment, 383 (78%) mothers preferred Amoxicillin DT over Amoxicillin suspension for the following reasons: dissolves easily 423 (80%), can be stored without refrigerator 217 (41%), no special care needed for storage 310(59%), easy to understand dosage 229 (50%), freshly prepared medication every time 180 (34%), easy to store remaining tablets in blister packs 195 (37%), tastes better than suspension 264 (50%), and easy to carry during travel 151(28%). Very few complained about using DT form. Parents showed good adherence and acceptance of dispersible tablets. DT formulations can be introduced for general use in community settings.

5557

GROUP B STREPTOCOCCUS ACUTE SUPPURATIVE PAROTITIS IN A YOUNG INFANT

Benazir Baloch Baloch
Aga Khan University Hospital, Karachi, Pakistan

Acute suppurative parotitis is a rare condition in young infants aged 0-59 days. It is characterized by swelling of parotid glands, fever, and pain, caused by drainage of pus into the oral cavity from the Stensen duct. Staphylococcus aureus is the most common organism while other gram-positive and gram-negative organisms are also documented. Prevalence is higher in male gender. In this report, we describe the case of a 55-day-old preterm young infant, previously healthy, admitted in the emergency department of The National Institute of Child Health, Karachi, Pakistan with complain of fever, reluctance to feed, and irritability with unremarkable general and oral physical examination. On second day of hospitalization, pre-auricular edema was observed bilaterally close to the angle of the jaw along with signs of inflammation, greater on the right side. Ultrasound findings showed bilateral parotid gland enlargement. Lab investigations showed neutrophilia with left shift and thrombocytosis, raised C reactive protein and positive blood culture for Streptococcus Pyogenes. Empiric antibiotic therapy was initiated with injection Ampicillin and Gentamicin and adjusted with Injection Meropenem when culture reports were available. The infant showed steady improvement of symptom and swelling after 48 hours of treatment and got discharged after 7 days. The repeat ultrasound done on 10th day after diagnosis which was normal, with resolved parotid swelling. This case illustrates the need for consideration of disease among young infants and its likelihood in both genders. It also emphasizes on the early institution of appropriate therapy of acute suppurative parotitis for faster recovery and prevention of complications. Furthermore, there is a need to investigate the causes and treatment of this disease in infants and should be considered as a differential diagnosis within this age group.

5558

EPIDEMIOLOGICAL BEHAVIOR OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) AT THE END OF THE COVID 19 PANDEMIC IN A HEALTH CARE CENTER IN MONTERÍA-COLOMBIA

Linda M. Chams, William E. Guerrero
Universidad de Córdoba, Monteria, Colombia

The epidemiological behavior of methicillin-resistant Staphylococcus aureus (MRSA) has been a major concern in healthcare centers worldwide. With the end of the COVID-19 pandemic, there has been an increased focus on other antibiotic-resistant pathogens, including MRSA.In Montería, Colombia, MRSA has been a constant problem in healthcare centers. With the COVID-19 pandemic, there has been an increase in demand for medical attention, which has increased the risk of MRSA transmission. Additionally, infection control measures, such as physical distancing and quarantine, may have been relaxed in some healthcare centers due to the need to prioritize care for COVID-19 patients. MRSA is a bacterial pathogen that is resistant to multiple antibiotics, making it difficult to treat. Moreover, it is highly contagious and can spread rapidly in healthcare settings if adequate infection control measures are not implemented. Therefore, the epidemiological behavior of MRSA at the end of the Covid 19 pandemic was evaluated in a health care center in Monteria, Colombia, during the period 2020-2022.A retrospective study was carried out, in which the records of bacterial isolates obtained in the different services of the health care center during the years 2020 and 2022 were consolidated. The biochemical identification tests and the definition of the antimicrobial susceptibility profiles for the isolated bacteria were performed with the automated MicroScan® system. An increasing prevalence of MRSA was found in the health care facility by year as follows: 2020 (9%), 2021 (51%) and 2022 (67%). In addition, the majority of MRSA cases were found to be acquired in the health care facility, suggesting that outbreaks were occurring in the health care facility.In conclusion, MRSA continues to be a major problem in health care facilities in Monteria, Colombia, and an increase in

the number of cases has been observed during the COVID-19 pandemic. It is important to implement adequate infection control measures to prevent and control the spread of MRSA in health care facilities.

5559

ISOLATION AND MOLECULAR IDENTIFICATION OF A STRAIN OF PSEUDOMONAS AERUGINOSA XDR (EXTENSIVELY DRUG RESISTANT) IN POLYTRAUMA PATIENTS IN MONTERIA, COLOMBIA

Linda M. Chams, William E. Guerrero, Carlos J. Castro
Universidad de Córdoba, Monteria, Colombia

Pseudomonas aeruginosa is a Gram-negative bacterium commonly found in the environment and in hospitals. Although some strains are harmless to humans, others can cause serious infections, especially in patients with compromised immune systems. P. aeruginosa strains that are extremely resistant to multiple antibiotics are called XDR (Extensively Drug Resistant). The aim of this study was to report the isolation and identification of a P. aeruginosa XDR strain in patients with polytrauma attended at a health center in the city of Monteria.Samples were taken from patients with polytrauma attended at a health center in the city of Monteria. The samples were processed in the microbiology laboratory by culture techniques and the P. aeruginosa XDR strain was identified by biochemical and antimicrobial sensitivity tests. Molecular identification of the strain was performed by PCR.A P. aeruginosa XDR strain was identified in four polytrauma patients. The strain showed resistance to multiple antimicrobials, including carbapenemics, making it a high public health risk strain. Molecular identification confirmed the presence of the strain.The report of the isolation and identification of a strain of P. aeruginosa XDR in patients with polytrauma is important from a public health point of view because this bacterium is known for its ability to resist multiple antibiotics, which makes it a threat to the health of the general population, especially for those who are hospitalized or who have weakened immune systems.In this sense, it is essential to take preventive measures to avoid the spread of the bacterium, such as infection control in health centers, training of health personnel in the proper management of infected patients and the implementation of epidemiological surveillance protocols for the early detection of infections. In addition, strategies for the appropriate use of antibiotics should be promoted to avoid the development of bacterial resistance.

5560

MYCOBACTERIUM LEPRAE ANTIGEN-SPECIFIC ANTIBODY PROFILING AND CYTOKINE ANALYSES REVEAL UNIQUE SIGNATURES OF LEPROSY AS WELL AS IMMUNE CHANGES WITH SCHISTOSOMA MANSONI CO-INFECTIONS

Pedro Marcal[1], Anushka Saha[2], Trirupa Chakraborty[3], Lorena Oliveira[4], Lucia Fraga[5], Jishnu Das[3], Aniruddh Sarkar[2], Jessica Fairley[6]
[1]Universidade Federal de Juiz de Fora (UFJF-Campus GV/PMBqBM), Governador Valadares, Brazil, [2]Georgia Institute of Technology, Atlanta, GA, United States, [3]University of Pittsburgh, Pittsburgh, PA, United States, [4]Universidade Vale do Rio Doce - Univale, Governador Valadares, Brazil, [5]Universidade Federal de Juiz de Fora (UFJF-Campus GV/PMBqBM), Governador Valadares, Brazil, Governador Valadares, Brazil, [6]Emory University, Atlanta, GA, United States

The lack of commercially available laboratory tests for conclusive early diagnosis of leprosy has motivated the search for novel methods for accurate diagnosis and characterization of disease states. In addition, helminth infections appear to be associated with leprosy but immune mechanisms underlying these associations are not clear. We have developed a multiplexed 'Ab-omics' platform for deep biophysical characterization (both Fab & Fc ends) of a broad set of antigen-specific Abs including not only their isotype and subclass but also glycosylation and Fc receptor binding. Here, we apply the Ab-omics pipeline to sera from patients (n=35, from Minas Gerais, Brazil), clinically diagnosed with leprosy, using multiple Mycobacterium leprae antigens (Ag85B, GroES, Bacterioferritin, CFP-10, ML2567, PGL-1). Antigen-coated barcoded beads were incubated with serum and probed with various fluorescently labeled isotype and subclass probes, tetramerized Fc receptors and lectins. A feature selection model LASSO was used to identify biomarkers for leprosy. For T-cell mediated immune response, M. leprae stimulated PBMC were analyzed for cytokines and chemokines by flow cytometry. LASSO was able to identify signatures that distinguish leprosy+ and leprosy- samples with an AUC of 0.75. We also found statistically significant stronger FcR3A and FcR2B binding for the ML2567; stronger IgG, IgG2, FcR2A binding for GRoES; and stronger binding for FcR2A, FcR3B, IgG3 for the ML LAM in leprosy (without coinfection) compared to individuals without leprosy. T-cell response analyses revels higher TNF-α and CXCL8 associated with co-infection; IL17 and IFN-γ lower in co-infection. These immune profiles not only distinguish leprosy from non-leprosy but also suggest an impact of Schistosoma mansoni co-infection on both cell-mediated and humoral immunity. In addition, this Ab-omics approach can lead to discovery of biomarkers that complement clinical diagnosis as well as increase our understanding of the role of helminth co-infections in the susceptibility of clinical leprosy.

5561

MAPPING CHOLERA HOTSPOTS IN THE ELIMINATION PROCESS IN CAMEROON, 2016-2022

Mendjime Patricia, Dibog Bertrand, Yopa Sandra, Tonye Tonye, Wahhab Abdoul, Defo Ivan, Essoh Linda, Etoundi Mballa Georges Alain
Ministry of Public Health, Department for the Control of Disease, Cameroon

According to the "Ending Cholera: A Global Roadmap to 2030" initiative of the Global Task Force for Cholera Control (GTFCC) in which Cameroon was enrolled, one of the requirements for identified countries is to have an updated map of their hotspots for prioritization of elimination actions, hence the objective of this study to identify cholera hotspots in Cameroon. We conducted a retrospective study of cholera data from the 10 regions of Cameroon with risk analysis carried out over a period of 06 years from January 2016 to December 2021. A 5-step approach was used. A preliminary mapping based on calculation of the relative burden of disease according to WHO threshold calibration was done. A second mapping used the vulnerability criteria, namely: geographical accessibility, hygiene and sanitation, movement of people, access to drinking water and geographical location. The third prioritization was made by integrating the first two. A final prioritization and mapping were obtained after reviewing the vulnerability criteria with joint national experts. A classification of districts included "low priority (LP)", "medium priority (MP)" or "high priority (HP)". Data were extracted from DHIS2 and MAPE forms; GTFCC guideline and additional EXCEL-developed data tools were used to analyze vulnerability criteria and enable risk classification. QGIS software was used to present Health district (HD) hotspot prioritization. The years 2019 and 2020 recorded the highest number of cases with 1931(35.2%) and 1895(34.5%) respectively. There was a drop in the number of cases in 2017 (from 78 to 22) after which, an exponential increase in cases with a peak in 2019 (1931 cases). Mapping identified 101 (53%) priority HDs, of which 29 (15%) were of high priority, bringing the percentages of at-risk population to 63.3%. The Far North, North, South West, Littoral regions had respectively the highest number of hotspots, i.e. 73(72%). The North and Littoral regions have the largest number of HP HDs, respectively 11(39%) and 6(20.7%). We recommend taking into account the prioritization of hotspots for the elaboration of the cholera elimination strategic plan of Cameroon.

5562

DESERT SORES: THE SCOURGE OF THE SAS "ROGUE HEROES" IN NORTH AFRICA, 1941-1943

David P. Adams[1], Michael Kent[2]

[1]University of Galway, Galway, Ireland, [2]Point University, Savannah, GA, United States

"Desert Sores: The Scourge of the SAS 'Rogue Heroes' in North Africa, 1941-1943" Ben Macintyre's 2017 book, Rogue Heroes, has sparked renewed interest in the operations of Special Air Service (SAS) personnel in the North African Campaign. Their unit became famous for swift, highly mobile raids on Italian and German posts along the Mediterranean coast throughout 1942. Their attacks, carried out on twin machine gun-kitted jeep laden with four well-armed men, played a significant role in the defeat of the Axis in North Africa. Desert life, however, took a physical toll on the SAS units. "Desert sores," vividly featured in an episode of the Netflix television series based on Macintyre's historical account, became a particular problem. Unable to bathe with any regularity, many men developed these painful ulcerated lesions. In severe cases, they became physically debilitating. Their precise aetiology, however, remained unclear. Was it a pathogen? If so, was it a bacterium or a parasite of some kind? Perhaps it was virtual absence of personal hygiene and chronic skin irritation the sand caused? What therapy worked best? It was not until the end of WWII that these puzzling questions were satisfactorily solved. This presentation, relying heavily on biomedical sources and historical accounts from WWII, will trace the evolution of the desert sores debate among British troops in North Africa. More specifically, it will examine their impact on SAS operations. The evolution of this debate reveals as much about competing schools of thought in tropical medicine as it does about the ever-expanding field of 20th-century microbiology.

5563

MULTIFACETED REALITIES OF SCRUB TYPHUS: A CASE SERIES FROM SOUTHERN INDIA

Diviya Bharathi Ravikumar[1], **Barath Prashanth Sivasubramanian**[2], Sruthi Nandhaa Shanmugam[3], Merilyn Jerry[4], Raghavendra Tirupathi[4]

[1]Employees State Insurance Corporation Medical Collegeand post graduate institute for medical science and research, Chennai, India, [2]University of Texas Health Science Centre, San Antonio, TX, United States, [3]Kasturba medical college, Mangalore, India, [4]Keystone Infectious Diseases, Chambersburg, PA, United States

Scrub typhus is an acute febrile illness caused by Orientia tsutsugamushi, a gram-negative bacillus commonly occurring in Asia- Pacific region. It is transmitted to humans by the bite of an infected Leptotrombidium mite which then causes vasculitis with endothelial dysfunction resulting in widespread vascular damage. Scrub typhus is a serious disease that can cause a range of complications, including thrombocytopenia, meningitis, acute respiratory distress syndrome, and, rarely, myocarditis, underscoring the importance of early diagnosis and prompt treatment. We examine four cases of scrub typhus and review the literature to emphasize the importance of considering scrub typhus in patients of all age groups from endemic areas presenting with fever, thrombocytopenia, or transaminitis, regardless of typical clinical features. The characteristic lesion at the site of mite feeding, eschar, was present in two cases. Fever and thrombocytopenia or transaminitis were commonly noted. One of the cases involved a middle-aged woman who was diagnosed with typhus-induced myocarditis. ECHO showed global hypokinesia of the left ventricle, grade 3 left ventricular diastolic dysfunction and an ejection fraction of 30%. Post-treatment ejection fraction improved to 64%. In addition, a 23-day-old neonate with poor feeding and seizures was diagnosed with late-onset sepsis with meningitis due to bacteremia, confirmed by a lumbar puncture showing neutrophilic predominance. In all cases, scrub typhus was confirmed with a positive qualitative IgM ELISA. Though quantitative and paired titers are preferred, due to resource limitations, single qualitative titers were performed at the time of hospital admission. This case series demonstrated marked responses to doxycycline. It is important that healthcare providers evaluate the patient's exposure history, along with clinical presentation, to diagnose scrub typhus. Confirmation of the diagnosis is typically done through serological testing.

5564

THE UNIVERSAL VITAL ASSESSMENT SCORE PREDICTS MORTALITY IN PATIENTS WITH COVID-19 IN RWANDA

Gashame Dona Fabiola[1], Theogene Twagirumugabe[1], Christopher C. Moore[2], Kwame A. Boateng[2]

[1]University of Rwanda, Kigali, Rwanda, [2]University of Virginia, Virginia, VA, United States

COVID-19 ranges from asymptomatic infection to the acute respiratory distress syndrome (ARDS). There are few data regarding clinical outcomes from COVD-19 from low income countries (LICs), including Rwanda. Accordingly, we aimed to determine 1) outcomes of patients admitted to hospital with COVID-19 in Rwanda, and 2) the ability of the Universal Vital Assessment (UVA) score to predict mortality. We conducted a retrospective study of patients aged ≥ 18 years hospitalized with laboratory confirmed COVID-19 at the University Teaching Hospital of Butare (CHUB), Rwanda from May-October 2021. For each subject, we calculated the UVA mortality risk score, which has been previously validated in patients hospitalized in sub-Saharan Africa. We used logistic regression to determine predictors of mortality and considered $P<0.05$ to be significant. Of the 150 patients included, 83 (55%) were female and the median (IQR) age was 61 (43-73) years. The median (IQR) of length of stay was 6 (3-10) days. Hypertension was identified in 36 (24%) of 150 and was the most common comorbidity. Respiratory failure occurred in 69 (46%) of 150 including 34 (23%) who developed ARDS. The case fatality rate was 44%. Factors independently associated with mortality included acute kidney injury (aOR 7.99, 95% CI 1.47-43.22, p=0.016), COVID-19 severity status (aOR 3.42, 95% CI 1.06-11.01, p=0.039), and the UVA score (aOR 7.15, 95% CI 1.56-32.79, p=0.011). The UVA score at admission had good discrimination for mortality with an area under the receiver operating characteristic curve of 0.85 (95% CI 0.80-0.92). At a UVA score cut-off of 4, the sensitivity, specificity, positive predictive value, and negative predictive value for mortality were 57.58%, 92.85%,86.36% and 73.58% respectively. Patients admitted to CHUB with COVID-19 had high mortality, which was predicted by the UVA score. Calculation of the UVA score in patients with COVID-19 in LICs may assist clinicians with triage and other management decisions.

5565

THE PREVALENCE OF MENSTRUAL DYSFUNCTION FOLLOWING COVID-19 INFECTION IN THAILAND

Rebecca Walshe[1], Watcharagan Kaewwanna[2], Kamonwan Kaprakhon[2], Chayanan Chaowanklang[2], Ellen Beer[1], Siriwan Tangjitgamol[3], Rapeephan Maude[1]

[1]Ramathibodi Hospital, Bangkok, Thailand, [2]Medpark Hospital, Bangkok, Thailand, [3]Vajira Hospital, Bangkok, Thailand

There is a lack of information in the literature describing menstrual dysfunction following infection with COVID-19. A recent systematic review found 12 studies evaluating menstrual cycle changes during the pandemic; only 3 specifically assessed the impact of infection. This case series aims to assess the prevalence and nature of menstrual changes following COVID-19 infection in Thailand. Ninety-six participants were recruited to the study. All had received inpatient care for COVID-19 at MedPark Hospital in Bangkok, Thailand. They completed a survey including menstrual history before and after illness. Basic demographic data and COVID-19 test results were collected from electronic patient records. To analyse menstrual disruption, we reviewed a subset consisting of female patients under the age of 50. Of 96 patients, 60 (62.5%) were female, of which 44 (73%) were under 50 years old. Mean age under 50 was 31.8, with a range of 15-47 years. Six (13.6%) reported menstrual dysfunction prior to COVID-19 infection; 38 (86.4%) reported no previous dysfunction. After infection, 11 (25%) reported a change in their menstruation, 6 of whom had

previously regular periods; 25 (56.8%) reported no menstrual dysfunction; and 8 (18.2%) were pregnant. Reported changes include irregular cycles or missed periods (n=5); shorter duration (n=3); heavy bleeding (n=2); and longer duration (n=1). This observational study found that while the majority of participants reported no menstrual disturbance following covid-19 infection, a proportion (11, 25%) reported a change. The nature of menstrual dysfunction was varied, with irregular/missed cycles and shorter cycles most common. Other studies with larger sample sizes have indicated that lighter bleeding and a prolonged cycle are commonly reported. Eight (18.2%) participants reported pregnancy. Although a small sample size, this suggests that short-term fertility was not affected in these women. Larger samples and prospective data collection will be valuable to further explore the impact of COVID-19 infection on menstruation patterns and its implications for patients.

5566

PATTERNS AND PREDICTORS OF MORTALITY WITHIN THE FIRST 24 HOURS OF ADMISSION AMONG CHILDREN AGED 1-59 MONTHS AT A REGIONAL REFERRAL HOSPITAL IN SOUTH WESTERN UGANDA

Moses Ochora

Mbarara University of Science and Technology, Mbarara, Uganda

Most deaths among children under 5 years occur within the first 24 hours of hospital admission from preventable causes such as diarrhea, pneumonia, measles, malaria, and HIV/AIDS. This is worsened by socioeconomic factors such as delays seeking health care, delayed interventions, financial limitations, unavailability of life-saving equipment, and inadequate support services. The demographic and clinical predictors of death within 24 hours of hospital admission are not yet well documented in our setting. This study aimed to describe the patterns and predictors of mortality within the first 24 hours of admission among children aged 1-59 months admitted at Mbarara Regional Referral Hospital. We conducted a prospective cohort study among 208 children aged 1-59 months admitted at the Mbarara Regional Referral Hospital. Participants were consecutively enrolled and pre-hospital, clinical, and laboratory factors that predicted their mortality within 24 hours of in-hospital admission were studied. Patterns of mortality were described using proportions, means and median and statistical analysis of predictors of mortality was done using multivariate regression. The mortality rate within the first 24 hours of admission was 7.7% (16), the median time to death was 7 hours and death was higher among infants. Severe pneumonia, severe acute malnutrition, and malaria accounted for 26.4%, 23.5%, and 11.5%, respectively of deaths. Admission during the night (p-value 0.047, AHR 3.7 (95% CI 1.02-13.53)) and having an abnormal neutrophil count (p-value 0.034, AHR 3.5 (95% CI 1.10-11-31) were predictive of mortality. The most common causes of death within 24 hours of admission are pneumonia and severe acute malnutrition. The mortality rate was higher among infants <12 months (9, 56.2%) than older children (7, 43.8%). Children who are admitted at night or have an abnormal neutrophil count should receive extra monitoring and interventions due to a higher risk of mortality within 24 hours of admission.

5567

RECONSTRUCTIVE SURGERY FOR THE NEGLECTED TROPICAL DISEASES (NTDS): GLOBAL GAPS AND FUTURE DIRECTIONS

Kala T. Pham[1], Peter J. Hotez[1], Kristy L. Hamilton[2]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Private Practice, Houston, TX, United States

Several neglected tropical diseases (NTDs) are highly disfiguring, particularly those in resource-poor countries that lack access to basic surgeries. There has been a push to integrate surgeries into treatment programs for NTDs. In this paper, we provide an overview of the major disfiguring NTDs and discuss the processes and barriers that impede access to reconstructive surgical treatments or their integration into health systems. A review of the literature was conducted using the online database PubMed from 2008 to 2021 with the specific diseases listed as neglected tropical diseases either on the World Health Organization (WHO) or the PLoS Neglected Tropical Disease Web sites. Reference lists of identified articles and reviews were also searched, as were databases from the WHO's Weekly Epidemiological Record. Success in the surgical treatment and post-operative care of disfiguring NTDs would benefit from standardization and harmonization of surgical approaches and procedures. In some settings, reconstructive surgery should be used cautiously, emphasizing appropriate use of antibiotics, partnerships with global and local surgical teams, and local capacity building. Preventative hygiene approaches remain paramount in resource-poor areas. In conclusion, surgery is a promising treatment for NTDs that result in disfigurement and disability. The expansion of local capacity building, with medical trips and surgical training of local health workers, together with the development of universal surgical protocols remain essential cornerstones for NTD reconstructive surgery. Antibiotics and drug management should comprise key first steps before turning to surgery.

5568

PATTERN OF OCCURRENCE, CLINICOPATHOLOGICAL PRESENTATION AND MANAGEMENT OF SALIVARY GLAND TUMOURS AMONG PATIENTS ATTENDING MUHIMBILI NATIONAL HOSPITAL, TANZANIA

David K. Deoglas, Boniphace M. Kalyanyama, Jeremiah R. Moshy, Shafii S. Ramadhani, Paulo J. Laizer

Muhimbili University of health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

Tumours of salivary glands form one of most heterogeneous groups of lesions accounting for 2.8% and 10% of all head and neck tumours. The tumours have overlapping clinical and histological characteristics of benign and malignant salivary gland tumours which results in difficulty in diagnosis which mostly require experienced personnel. Delay in presentation has led to challenging management and poor outcomes. Authors set out to investigate pattern of occurrence, clinicopathological presentation and management of salivary gland tumours in Tanzania. A descriptive prospective hospital-based study was conducted at Muhimbili National Hospital between May 2021 and April 2022. Patient interview was conducted by investigator enquired about the socio-demographics main complaint(s), associated symptoms and examination findings. Tissue biopsies which were taken from all patients for histological investigation for diagnosis confirmation. Surgical and post-operative histology details were recorded. Data entry, cleaning, coding and analysis were done by using the SPSS 23.0 software. Ethical clearance was sought from the Ethical Board of MUHAS. A total of 597 patients with head and neck tumours were seen and among these, 63 patients were diagnosed with salivary gland tumours making prevalence of 10.56%. Majority (68.3%) of patients had salivary gland cancers, and most of patients (73%) first sought health care more than 3 months after initial symptom. Main reason for delay was neglect (41.3%). All benign salivary gland tumours were pleomorphic adenomas while adenoid cystic carcinoma was most common salivary gland cancer (39.5%). Patients with salivary gland cancers presented with ulcerated lesions, bleeding, tender, indurated, fixed to underlying structures, paraesthesia and facial nerve paralysis. Surgery was done on 46.5% of patients and the remaining were treated by palliative chemoradiotherapy. In conclusion, salivary gland cancers presented in late stages associated with patient's poor healthcare-seeking behaviour leading to treatment delays more palliative than curative therapy

5569

AETIOLOGY OF ACUTE UNDIFFERENTIATED FEBRILE ILLNESS AT A TERTIARY CARE CENTRE IN EASTERN UTTAR PRADESH, INDIA

Vishwa Deepak Tiwari[1], Thakur Shubh Narayan Rai[1], Mayank Gangwar[2], Urvashi Geeta Rai[1], Gopal Nath[2], Jaya Chakravarty[1]

[1]Department of General Medicine, Institute of Medical Sciences, Varanasi, India, [2]Department of Microbiology, Institute of Medical Sciences, Varanasi, India

Acute undifferentiated febrile illness (AUFI) a common presenting complaint, can cause significant mortality and morbidity if left undiagnosed. There is a regional variation in the aetiology of AUFI. Moreover, similarity in the symptoms makes an accurate clinical diagnosis difficult without laboratory confirmation. Thus, this study was done to identify the common aetiology of AUFI at a tertiary care centre in Eastern Uttar Pradesh, India. This cross-sectional study was conducted in SSL Hospital, Banaras Hindu University, Uttar Pradesh, India, between May 2021 and May 2022. All adult patients presenting with fever <14 days without any localizing sign were included in this study. ELISA tests were performed on all samples by Leptospira IgM ELISA, Chikungunya IgM ELISA, Scrub Typhus IgM ELISA , DENV IgM Capture ELISA, as per the manufacturer protocol. During the study period, 121 patients admitted with AUFI were included in the study. The most common aetiology found was Dengue comprising 41 (33.88%) of the total AUFI patients whereas 22/41 patients were found positive for dengue alone and rest were having co-infection in which Scrub Typhus was the most common co-infection. Second most common aetiology were Leptospirosis and Scrub Typhus comprising 29 (23.96%) patients each whereas 8/29 patients were positive for Leptospirosis alone and Scrub Typhus alone was positive in 10/29 patients. Remaining 21/29 patients of Leptospirosis had co-infections majorly of scrub typhus. Whereas in the remaining 19/29 patients of Scrub typhus, the most common co-infection was Leptospirosis. The patients found positive for Chikungunya were 9(8.49%) whereas only 6 were positive for Chikungunya only. Remaining 3 patients were having double co-infection of Scrub Typhus along with Leptospirosis. There were 13(10.74%) patients not found positive for any of the aetiology stated above and needed further clinical investigations. The most common cause of AUFI was viral. Availability of cost-effective serological test for dengue, scrub typhus and leptospirosis at primary health care setting would lead to early diagnosis and effective management of AUFI in this region.

5570

IMPROVING THE REPEATABILITY OF A QUANTITATIVE G6PD POINT-OF-CARE DIAGNOSTIC THROUGH VARIATION OF TEST PROCEDURES

Arkasha Sadhewa[1], Alina Chaudhary[2], Lydia V. Panggalo[3], Angela Rumaseb[1], Nabaraj Adhikari[2], Sanjib Adhikari[2], Komal R. Rijal[2], Megha R. Banjara[2], Ric N. Price[1], Benedikt Ley[1], Prakash Ghimire[2], Ari W. Satyagraha[4]

[1]Menzies School of Health Research, Darwin, Australia, [2]Tribhuvan University, Kathmandu, Nepal, [3]Exeins Health Initiative, Jakarta, Indonesia, [4]Eijkman Center for Molecular Biology, Jakarta, Indonesia

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common enzymopathy worldwide and the main risk factor for 8-aminoquinoline (8AQ) induced haemolysis. The introduction of novel, short course, 8AQ-based treatment regimens for the radical cure of Plasmodium vivax (P. vivax) presents a good opportunity for more effective P. vivax control, however, widespread use will require stringent G6PD testing at the point-of-care (PoC). Diagnosing heterozygous women with intermediate G6PD activity at the PoC requires a quantitative G6PD measurement. In a controlled laboratory setting, the quantitative PoC diagnostic G6PD Standard (SD Biosensor, ROK) has good repeatability, however, anecdotal evidence suggests that this may not be the case in real-life settings. We assessed whether the repeatability of the G6PD Standard in real-life settings can be improved by varying test procedures. In a pilot study conducted in Australia, G6PD activity was tested in three volunteers using four different test procedures and the standard method; two methods used capillary blood, and three methods used venous EDTA blood. Each volunteer was tested ten times pairwise with each method. The pilot study found that using venous blood with a modified pipetting method (blood is absorbed from the pipette to the test membrane rather than dispensed) improved the repeatability of the G6PD measurements. The median difference between paired readings was 0.3U/gHb (IQR: 0.2-0.4) for the novel method compared to 0.5U/gHb (IQR: 0.2-0.9) for the manufacturer-recommended method. However, subsequent field studies in Indonesia (n=60) and Nepal (n=120) found no significant improvement compared to the standard manufacturer-recommended method. The field study in Nepal is ongoing with more than 60% of participants enrolled to date. We found that the repeatability of the G6PD Standard can be improved by using venous instead of capillary blood. The use of venous blood rather than capillary blood may improve repeatability since the variation in blood collection procedures is reduced, though we could not consistently replicate this improvement in field settings.

5571

MISSED OPPORTUNITIES: SCREENING FOR CHAGAS DISEASE AND STRONGYLOIDIASIS IN LIVER AND KIDNEY TRANSPLANT RECIPIENTS BORN IN LATIN AMERICA

Danielle Martin[1], Shaina Rodrigues[2], Katherine R. McAleese[2], Adrienne Showler[2]

[1]Georgetown University School of Medicine, Washington, DC, United States, [2]Georgetown University Hospital, Washington, DC, United States

Strongyloides stercoralis and Trypanosoma cruzi are common chronic parasitic infections in U.S. residents born in Latin America. Although immunocompetent individuals are often asymptomatic, patients receiving iatrogenic immunosuppression can develop life-threatening complications from disseminated strongyloidiasis and T. cruzi reactivation. We evaluated pre-transplant screening practices in liver and kidney recipients with epidemiologic risk factors for both parasites. We retrospectively identified all Hispanic/Latinx adult liver or kidney transplant recipients at MedStar Georgetown University Hospital in Washington, DC from January 1,2019 to December 31,2021. We included only patients born in Mexico, Central or South America. We recorded demographics, transplant characteristics, diagnostics, antiparasitics, and whether infectious disease (ID) consultation was performed. Sixty-five Latin-American born patients received transplants, including 8 (12%) from Mexico, 45 (69%) from Central America, and 12 (19%) from South America. Recipients from El Salvador accounted for 63%. Thirteen patients (20%) received Strongyloides screening, of which 2 (15%) tested positive. Liver recipients were more likely to be screened than kidney recipients (p<0.001). Eosinophilia was not associated with Strongyloides screening (p=0.09). Nine patients (14%) received T. cruzi screening, all with normal tests. There was no difference in screening based on the presence of EKG changes (p=0.1). All patients screened for T. cruzi or S. stercoralis had received pre-transplant ID consultation for an unrelated reason, most commonly latent tuberculosis infection. Despite epidemiologic risk factors, the majority of Latin-American born recipients of liver and kidney transplants at our institution did not receive pre-transplant Strongyloides or T. cruzi testing. Improved screening protocols based on geographic exposure history are needed to identify chronic parasitic infections prior to immunosuppression. Routine ID consultation for transplant candidates with prolonged residence abroad could increase screening uptake.

5572

RETROSPECTIVE EPIDEMIOLOGICAL STUDY ON THE EFFECTIVENESS OF VISCERAL LEISHMANIASIS TREATMENT PROTOCOLS AND RISK FACTORS FOR RELAPSE IN TIATY EAST AND TIATY WEST SUB-COUNTIES, KENYA

Grace C. Kennedy[1], Katherine O'Brien[1], Hellen Nyakundi[2], Mwatela Kitondo[2], Wilson Biwott[3], Richard G. Wamai[4]

[1]Department of Health Sciences, Bouve College of Health Sciences, Northeastern University, Boston, MA, United States, [2]African Center for Community Investment in Health, Chemolingot, Kenya, [3]Chemolingot Sub-county Hospital, Chemolingot, Kenya, [4]Department of Cultures, Societies, and Global Studies, College of Social Sciences and Humanities, Northeastern University, Boston, MA, United States

This project seeks to determine the effectiveness of current treatment protocols for visceral leishmaniasis (VL) in Tiaty East and Tiaty West Sub-counties, Kenya, and identify risk factors for relapse. The 2017 Republic of Kenya Ministry of Health's Guidelines for Prevention, Diagnosis, and Treatment of Visceral Leishmaniasis require patients to undergo follow-up examination six months after completing treatment to determine final cure, relapse, death, or loss to follow-up as well as assess for Post Kala-azar Dermal Leishmaniasis (PKDL). However, due to situational difficulties including lack of transportation, distance to health facilities, poverty, and low health-seeking behavior, follow-up is rarely done leading to a large gap in long-term treatment effectiveness data. Few studies have been done on VL relapse, but the rate has been shown to be between 1.4% and 14.4% globally with much higher rates in Eastern Africa. No study has been done on VL follow-up in Kenya with current treatment protocols. This study was conducted at Chemolingot Sub-county Hospital (CSCH) in Baringo, Kenya during February and March 2023 on patients living in Tiaty East and West that were treated before August 2022 at CSCH and Kimalel Health Centre. Patients were tracked down using contact information from medical records and Community Health Volunteer searches and referrals. Patients received a follow-up examination from a clinician including history taking, physical examination, and hemoglobin level to assess for the above outcomes. Compensation for the cost of travel to the health facility was provided. Preliminary results of 18 patients show all patients as fully cured. Preliminary analysis of relapse cases from medical records at CSCH show a low relapse rate as well, but further conclusions about relapse rate and risk factors cannot be drawn before formal analysis. From preliminary data, current treatment protocols in Kenya appear to be effective. Given the upcoming change to a new drug combination and shorter treatment period, study results should be compared to future treatment protocol follow-up data.

5573

IMPLEMENTING LABORATORY QUALITY MANAGEMENT SYSTEMS IN GHANA - A BASELINE QUALITY AUDIT OF ACCREDITATION READINESS IN LOWER-TIER HEALTH FACILITIES

Emma Edinam Kploanyi[1], Joseph Kenu[1], Benjamin Buade[1], Benedicta K. Atsu[1], David A. Opare[2], Franklin Asiedu-Bekoe[3], Lee F. Schroeder[4], David W. Dowdy[5], Alfred Yawson[6], Ernest Kenu[1]

[1]School of Public Health, University of Ghana, Accra, Ghana, [2]National Public Health & Reference Laboratory, Ghana Health Service, Accra, Ghana, [3]Public Health Division, Ghana Health Service, Accra, Ghana, [4]Department of Pathology & Clinical Laboratories, University of Michigan, Ann Arbor, MI, United States, [5]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Department of Community Health, University of Ghana School of Medicine and Dentistrya, Accra, Ghana

In the last decade, the implementation of the Stepwise Laboratory Improvement Process Towards Accreditation (SLIPTA) in Africa has targeted laboratory performance to characterize error and improve patient safety but often targets the highest-tier laboratories. The current study implemented a SLIPTA quality audit in a representative sampling of Ghanaian health facilities. An audit using a modified SLIPTA checklist was carried out in health facilities randomly selected within districts stratified by ecological zone, remoteness from zonal Laboratories, and population density. The audit was conducted in regional and district hospitals, polyclinics, and sub-district facilities from February 2021 to July 2022. The Wilcoxon rank sum test and quantile regression were used to characterize the associations between laboratory characteristics and SLIPTA scores. Forty-nine health facilities were audited with the majority in the public health sector (81.6%). Laboratories performed a median of 30 (Interquartile range: 10 – 90) tests daily, with 40.8% of facilities only performing point-of-care testing. The median SLIPTA score was 44.1% (Interquartile range: 24.0% – 56.7%) with hospitals recording the highest (55.9%). Of the 12 SLIPTA quality systems essentials, performance was highest in Organization & Personnel, and poorest in Client Management and Occurrence Management & Process Improvement. In multivariable regression, the median SLIPTA scores reduced for facilities located in the Northern zone [-21.5(95% CI=-31.7- -11.3; p<0.001)], compared to those in the Southern zone and also for facilities that performed only point-of-care testing [-18.2(95% CI=-31.6- -4.7; p<0.01)] compared to moderate to high complexity testing. The majority of the laboratories audited were yet to attain international accreditation readiness. Quality compliance was equivalent to 1 star for hospitals but lower for the other facility tiers. There is a need to conduct a root cause analysis for laboratory quality with commensurate policy changes to enhance performance.

5574

ASSESSMENT OF TREATMENT OUTCOMES OF HUMAN IMMUNODEFICIENCY VIRUS POSITIVES TRANSITIONED FROM TENOFOVIR/LAMIVUDINE/EFAVIRENZ TO DOLUTEGRAVIR REGIMEN COMBINATION IN A NIGERIAN TERTIARY HOSPITAL

Omobola Yetunde Ojo

Federal Medical Centre, Abeokuta, Nigeria

Due to the introduction of dolutegravir as a replacement for nevirapine or efavirenz in a fixed dose combination with Tenofovir/Lamivudine, as the preferred first-line option for the prevention and treatment of HIV infection, there is a need to assess the treatment outcomes of the new Tenofovir/Lamivudine/Dolutegravir (TLD) regimen in a Nigerian tertiary hospital. This retrospective study used data drawn from the treatment register of patients who transitioned from Tenofovir/Lamivudine/Efavirence (TLE) to TLD between January 2016 and January 2018. The data extracted were analyzed using SPSS statistical software version 20. Descriptive statistics were used to describe categorical and continuous variables. Chi-square test statistics was done to test for association between categorical variables and treatment outcomes and the level of significance was set at $p<0.05$. A total of 358 cases were reviewed. Their mean age was 44.29 ± 11.5 years and the majority 267 (74.6%) were females. Viral load suppression of ≤1000 copies/ml was achieved in 313 (87.4%) of cases while on TLE but increased to 339 (94.7%) when transitioned to TLD within the period of study. In addition, 36.3% had a high CD4 count while on TLE and this increased to 67.3% of those with high CD4 within the period of study. There was a statistically significant difference between the mean CD4 count while using TLE and then when transitioned to TLD (t=31.601; p-value-0.001). Treatment outcome was greatly improved in terms of virologic, immunologic, and clinical presentation among patients who transitioned from TDF/3TC/EFV to TDF/3TC/DTG in this study. The outcome of this study supports and encourages the use of TDF/3TC/DTG as the preferred first-line regimen in HIV treatment for the patient's maximum clinical benefit. This should be communicated to all stakeholders and policy-makers involved in the provision of effective healthcare service delivery in HIV management.

5575

IMPACT OF THE INTRODUCTION OF A PACKAGE OF DIAGNOSTIC TOOLS, DIAGNOSTIC ALGORITHM, AND TRAINING AND COMMUNICATION ON OUTPATIENT ACUTE FEVER CASE MANAGEMENT AT THREE DIVERSE SITES IN UGANDA: RESULTS OF A RANDOMIZED CONTROLLED TRIAL

James A. Kapisi[1], Asadu Sserwanga[1], Freddy E. Kitutu[2], Elizeus Rutebemberwa[3], Phyllis Awor[3], Stephan Weber[4], Thomas Keller[4], David K. Mafigiri[5], Deborah E. Sebatta[1], Philip Horgan[6], Sabine Dittrich[6], Catrin E. Moore[7], Olawale Salami[6], Pierro Olliaro[6], Juvenal Nkeramahame[6], Heidi Hopkins[8]

[1]Infectious Diseases Research Collaboration, kampala, Uganda, [2]Department of Pharmacy, Makerere University School of Health Sciences, kampala, Uganda, [3]Department of Health Policy, Planning and Management, Makerere University School of Public Health, kampala, Uganda, [4]ACOMED Statistics, Leipzig, Germany, [5]Social Work and Social Administration, Makerere University, kampala, Uganda, [6]FIND, the global alliance for diagnostics, Geneva, Switzerland, [7]Centre for Neonatal and Paediatric Infection, Institute for Infection and Immunity, St George's University of London, London, United Kingdom, [8]London School of Hygiene and Tropical Medicine, London, United Kingdom

Increasing trends of antimicrobial resistance are observed around the world, driven in part by excessive use of antimicrobials. Limited access to diagnostics particularly in low- and middle-income countries contributes to diagnostic uncertainty which may promote unnecessary antibiotic use. We investigated whether introducing a package of diagnostic tools, clinical algorithm, and training and communication messages could safely reduce antibiotic prescribing compared with current standard of care for febrile patients presenting to outpatient clinics in Uganda.This was an open-label, multi-center, two-arm randomized controlled trial conducted at three public health facilities (Aduku, Nagongera, and Kihihi health center IVs), between September 2020 to August 2021, comparing the proportions of antibiotic prescriptions and of clinical outcomes for febrile outpatients aged one year and older. The intervention arm included a package of point-of-care tests, a diagnostic and treatment algorithm, and training and communication messages. Standard-of-care was provided to patients in the control arm. A total of 2400 patients were enrolled with 49.5% in the intervention arm. Overall, there was no statistically significant difference in antibiotic prescriptions between the study arms; relative risk (RR 1.030, 95% CI 0.958-1.108). In the intervention arm, patients with positive malaria test results had a higher RR of being prescribed antibiotics (1.742 [1.517-2.000]) while those with negative malaria results had a lower RR (0.683, [0.625-0.748]). There was no significant difference in clinical outcomes. This study found that a diagnostic intervention for management of febrile outpatients did not achieve the overall desired impact on antibiotic prescribing at three diverse and representative health facility sites in Uganda.

5576

PREVALENCE OF CHRONIC KIDNEY DISEASE IN A COHORT OF GUATEMALAN AGRICULTURAL WORKERS 2020-2022: THE AGRICULTURAL WORKERS AND RESPIRATORY ILLNESS IMPACT (AGRI) STUDY

Diva M. Calvimontes[1], Molly M. Lamb[2], Neudy Rojop[1], Kareen Arias[1], Edgar Barrios[1], Jaime Butler-Dawson[2], Lyndsay Krisher[2], Melissa Gomez[1], Wanda Mejia[1], Claudia Paiz[1], Guillermo A. Bolanos[1], Lee .. Newman[2], Edwin J. Asturias[3], Daniel Olson[3]

[1]Fundacion para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala, [2]Colorado School of Public Health, Aurora, CO, United States, [3]University of Colorado School of Medicine, Aurora, CO, United States

Chronic kidney disease (CKD) has recently been identified as a major public health concern in Central American agricultural workers and has been linked to physically stressful working conditions and dehydration. We measured estimated glomerular filtration rate (eGFR) annually from 2020-2022 among banana plantation workers in southwest Guatemala enrolled in the longitudinal AGricultural workers and Respiratory Illness impact (AGRI) study. The cohort is primarily comprised of otherwise healthy young workers (mean age 30 (range 18-62) years; 84% male) who are economically vulnerable (58% report food insecurity) and live within a geographically broad (2,600 km2) catchment area in southwest Guatemala. eGFR screening was completed for 1,879 workers in 2020, 1,085 workers in 2021, and 602 workers in 2022. The prevalence of eGFR < 90 ml/min/1.73m2 was 33.0%, 26.6% and 30.9% (2020, 2021, and 2022, respectively) within which the prevalence of eGFR < 60 was 2.3%, 1.9%, and 2.3% (2020, 2021, and 2022, respectively). Of the 1,233 workers that received at least two annual eGFR screenings in this period, 237 (19.2%; mean age 37.0 years, range 18-60 years) were "at risk" for CKD (defined as eGFR < 90 at least twice), and 13 (1.1%; mean age 37.5 years, range 23-59 years) also met the definition for moderate/severe CKD (defined as eGFR < 60 at least twice). Regression models adjusted for sex showed that age was associated with moderate/severe CKD (Relative Risk = 1.07, 95% Confidence interval: 1.01 – 1.12), indicating a 7% increase in risk with each increasing year of age. Comorbidities and modifiable risk factors are being collected and will be examined in expanded regression models. The high prevalence of CKD in this relatively young population suggests the need for regular screening and follow-up in agricultural workers in similar work environments, which can then lead to programs to reduce modifiable risk factors of disease. Ongoing assessments include follow-up testing of those workers with moderate/severe CKD screening and continued annual screening of workers enrolled in the AGRI study.

IMPACT OF IMPROVED DIAGNOSTIC TOOLS, PRACTICES, TRAINING AND COMMUNICATION ON ACUTE FEVER CASE MANAGEMENT AND ANTIBIOTIC PRESCRIPTIONS FOR PATIENTS PRESENTING AT OUTPATIENT FACILITIES IN UGANDA

Deborah Ekusai- Sebatta[1], Elizeus Rutebemberwa[2], James A. Kapisi[1], Asadu Sserwanga[3], Freddy Kitutu[2], Heidi Hopkins[4], David K. Mafigiri[5], Philip Horgan[6]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Makerere University, School of Public Health, Kampala, Uganda, [3]Malaria Consortium, Kampala, Uganda, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Makerere University, department of Social work and social administration, Kampala, Uganda, [6]FIND, Evidence & Impact Oxford, Oxford, UK, United Kingdom

Antibiotic prescribing practices is one of the main causes of antimicrobial resistance. The study explored the key drivers and barriers to adherence to prescribing instructions by patients/caregivers.As part of a randomized trial, a qualitative assessment was done. This involved three arms of the study: pre-intervention, intervention and post-intervention. The intervention involved randomization of patients to either the intervention or control arm. A training and communication package was developed guided by the findings. Health workers were trained on the package for use with the intervention patients. It was pretested for clarity with sample patients. Meetings were held with policy makers to discuss the capacity, opportunity and motivational COM-B/TDF framework and behavior change techniqueThis study was conducted at three Health centres in Uganda; Aduku in Northern region, Kihihi in Western region, and Nagongera in the Eastern region.Focus groups discussions were conducted with patients who sought care from the health facility and in-depth interviews were conducted with health workers based on their role as clinicians and laboratory attendants. Content analysis identified two themes namely key drivers and barriers and the COM-B/TDF behaviour frameworks approach identified four themes.Results: 1) Key drivers included: drug availability, health worker knowledge and communication 2) Barriers included: use of treatment resorts and inability to buy drugs. Findings from the COMB-B/TDF showed that an opportunity like 1) good support network, 2) capability of the health workers with good knowledge, 3) cognition and interpersonal skills, 4) motivation and awareness from the training and communication package increased positive social and environmental factors to tackle poor adherence.

A SIMPLIFIED CAREGIVER DERIVED DIARRHEA SEVERITY SCORE (14DCODA) FOR USE IN SURVEYS WITH 14-DAY RECALL PERIODS: A VALIDATION STUDY NESTED WITH IN A VIRAL DIARRHEA SURVEILLANCE PROJECT IN AMAZONIAN PERU

Margaret Kosek[1], Maribel Paredes Olortegui[2], **Josh Michael Colston**[1], Greisi Hurico[2], Melinda Munos[3]

[1]University of Virginia School of Medicine, Charlottesville, VA, United States, [2]Asociacion Benefica PRISMA, Iquitos, Peru, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Diarrhea is a frequent syndrome in children in low- and middle-income countries (LMICs). While most diarrheal episodes are mild, some are severe and fatal, and the syndrome remains a leading cause of death in young children in LMICs. Nationally representative household surveys such as those conducted by DHS and MICS estimate diarrhea prevalence by asking caregivers about occurrence of diarrheal episodes in their children in the two-week preceding the interview. However, doubts have been raised about the reliability of illness recall over this period, leading to the exclusion of survey questions about the specific symptoms that might delineated severe from mild episodes. We address these questions by nesting a recall validation study within a larger diarrhea etiology study being carried out in Iquitos, a city in the Peruvian Amazon. Caregivers seeking care for children presenting with diarrheal illness were asked about symptoms for the 7 days prior to enrollment. At home visits 14 days later, they were then asked to recall the same illness features present on the day the child presented for care and on the days prior to presentation. CODA diarrhea severity scores were calculated for baseline ("gold standard") and at 14 day follow up (dCODA) and the latter compared for accuracy using ROC analysis. A dCODA score of 8 had an accuracy of 79.3% in classifying moderate to severe disease from mild disease as defined by the CODA score. Three symptom-specific questions that had a high accuracy included the maximum number of unformed stools in a 24-hour period (79.4%), days spent with fever (80.8%) and days of illness with vomiting (84.1%). We suggest that incorporating these three questions into household surveys may allow differentiation of episodes by severity across diverse contexts. This will be useful to improve estimates of health care coverage and understand the differential impact of disease specific interventions in reducing severe diarrheal disease.

HUMAN EXPOSURE TO ONCHOCERCA VOLVOLUS IN HIGH AND LOW RISK ONCHOCERCIASIS TRANSMISSION SETTINGS

Sellase A. Pi-Bansa[1], Kwadwo Frempong[1], Joseph Nyarko[1], Millicent Opoku[2], Selassie Afatodji[1], Franklin Ayisi[3], Sampson Otoo[1], Mawunyo Dogbe[1], Abena Nyarko[1], Aissatou Diawara[4], Sake de Vlas[5], Wilma Stolk[5], Daniel Boakye[1]

[1]Noguchi Memorial Institute for Medical Research (N.M.I.M.R), Greater Accra, Ghana, [2]La Trobe University, Bundoora, Australia, [3]African Regional Postgraduate Programme in Insect Science, Greater Accra, Ghana, [4]Global Institute for Disease Elimination, Abu Dhabi, United Arab Emirates, [5]Erasmus Medical Center, Rotterdam, Netherlands

Onchocerciasis caused by Onchocerca volvulus is transmitted by blackflies. Simulium damnosum are primary vectors in Africa. Onchocerciasis is the second leading cause of blindness after Trachoma. Community-directed treatment with ivermectin (CDTI) is the strategy for onchocerciasis control. A recently published modelling study shows that onchocerciasis elimination time depends on connectedness between villages either by human mobility or migrating flies. This study was therefore conducted to generate data to substantiate/improve findings from the study by investigating onchocerciasis infection in mobile individuals at low (5 km from breeding sites) and high risk (15 km from breeding sites) communities frequenting both settlements. The study was conducted in three villages each in onchocerciasis low and high risk areas in the Nkwanta North District of Ghana. A total of 539 participants from low risk (225) and high risk (314) communities had questionnaire administered to them to obtain biodata, movement, CDTI history, etc. Dried blood spots and skin snips were collected for OV 16 testing and microfilariae detection respectively. The overall serological prevalence for the six communities was 29.1%, (high risk: Kone=52.63%, Abunyanya=50.0% and River View=22.86%; low risk: Lancha=14.94%, Badule=17.72% and Gborsike=8.77%). This was significantly higher (P<0.0001) in high-risk (41.50%) than in low risk (14.35%) areas. Skin snip prevalence was (high risk: Kone=5.15%, Abunyanya=6.25% and River View=5.71%; low risk: Lancha=4.5%, and Badule/Gborsike=0.00%). Prevalence in high risk (5.73%) was significantly higher (P<0.0001) than in low risk (0.92%). Overall skin snip prevalence was 2.9%. Negative skin snips are currently being screened for parasites using RT PCR. Questionnaire data shows skin snip positive participants from Lancha spend ample time in high risk communities and their farms where they experience blackfly bites. During onchocerciasis elimination mapping phase, information on human movements (questionnaire) and diagnostics with high sensitivity (PCR) must be considered to guide policies and strategies.

COST-BENEFIT ASSESSMENT OF SURGICAL INTERVENTION FOR FILARIAL HYDROCELE PATIENTS AT THE PRIMARY HEALTH CARE LEVEL IN BANGLADESH

Shomik Maruf[1], Aishi Aratrika[1], Soumik Kha Sagar[1], Mohammad Sohel Shomik[1], Prakash Ghosh[1], Md Rasel Uddin[1], Md Shakhawat Hossain[1], Martin Siegel[2], MM Aktaruzzaman[3], Dinesh Mondal[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Department of Empirical Health Economics, Technische Universität Berlin, Berlin, Germany, [3]Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh

Lymphatic filariasis (LF) is the 2nd leading cause of disability, affecting 120 million people and endemic in 72 countries worldwide. One of the complications of chronic LF is hydrocele which reduces mobility, induces social stigma and depression, and drastically decreases the ability to work. Surgical correction of filarial hydrocele with minimal complications can help these people return to a socioeconomically productive life. The study evaluated the hydrocele-related lifetime economic loss and the surgical benefits compared to its cost based on the 838 hydrocelectomy surgeries conducted between March to June 2021. The data were collected before and one year after surgery. Assumptions included financial losses and gains for the patients. Area-based daily wage rates were used to determine average lifetime earning gain and discounted value from surgery to age 64 - the end of working life. We estimated the total costs and compared them with the benefit of the work capacity restored to determine the cost-benefit ratio. Further Incremental Cost-effectiveness ratio (ICER) was calculated to determine the intervention program's cost-effectiveness level. The total monetary benefit of the surgery was 3,892,118 USD (without discounting) and 2,700,505 USD (with discounting). The average lifetime income gain per patient was USD 4644 (without discounting) and USD 3222 (with discounting) and approximate cost-benefit ratio is 1:15. The ICER value (71 USD) makes the intervention highly cost-effective, as it is substantially lower than the per capita GDP of Bangladesh (1961 USD). The sensitivity analysis demonstrates that the results are robust to surgery cost variations. The colossal patient burden in Bangladesh warrants significant investment to reinstate these patients to a normal life. However, the study findings show that the required investment is minimal compared to the lifetime impact of the surgery on the patients, their families, and the country. Governments and international aid organizations should prioritize investing in similar projects to eliminate LF and help thousands by improving disability and averting poverty.

5581

BASELINE EVALUATION OF ONCHOCERCIASIS TRANSMISSION IN FOUR DISTRICTS OF NORTHERN GHANA

Andrew Abbott[1], Joseph Opare[2], Kofi Asemanyi-Mensah[2], Odame Asiedu[2], Ellen J. Doku[2], Anthony Tetteh-Kumah[2], Kofi Agyabeng[3], Ben Masiira[4], Thomson Lakwo[4], Gifty Boateng[5], Lorreta Antwi[5], E. Scott Elder[1], Jessica Prince-Guerra[1], Andrew N. Hill[1], Paul T. Cantey[1]

[1]United States Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Neglected Tropical Diseases Program, Ghana Health Services, Accra, Ghana, [3]Biostatistics Department, School of Public Health, University of Ghana, Legon, Ghana, [4]African Field Epidemiology Network, Kampala, Uganda, [5]National Public Health and Reference Laboratory, Ghana Health Service, Accra, Ghana

Onchocerciasis, a filarial disease transmitted by blackflies, is targeted by the World Health Organization (WHO) for elimination. The WHO-recommended serologic threshold for stopping MDA is Ov16 seroprevalence <0.1% in children <10 years; however, models suggest that a higher seroprevalence of ≤2% may be sufficient to indicate interruption of transmission. We sought to evaluate the 2% threshold using paired entomological and serological studies in 4 districts in Northern Ghana where transmission may have been interrupted. If the Ov16 seroprevalence in children 5–9 years is ≤2% and blackfly O-150 PCR positivity meets WHO stopping criteria, then MDA will be stopped, and the area monitored annually. Vector control began in Ghana in 1974 followed by mass drug administration (MDA) with ivermectin in 1998; baseline prevalence in the study area was 5–89%. In 2022, a baseline serosurvey of children 5–9 years was conducted. The districts were stratified by endemicity status and villages selected through probability proportionate to estimated size methodology. In villages, a multi-stage random sample of children were enrolled with parental permission. A separate convenience sample of children was selected from 5 first-line villages. Dried blood spots (DBS) were prepared from venipuncture specimens, then eluted for analysis with Ov16 IgG4 rapid diagnostic tests (RDT). Results were available for 2,087 children from 65 villages. RDT results were positive in 31 children from 18 villages. When adjusted for survey design, the overall positive percentage was 1.3% (95% CI 0.6%–2.0%) for the districts. District positive percentages ranged from 0.5% (95% CI 0.1%–1.7%) to 2.2% (95% CI 0.8%–4.6%). Mapping of the positive villages did not reveal clustering. Study results show the Ghana program has significantly reduced transmission and met the study serologic criteria for stopping MDA. Results from the ongoing Ov16 ELISA of DBS and O-150 PCR testing in blackflies will be needed for a stop-MDA decision. Demonstration that a higher serologic threshold is consistent with interruption of transmission would facilitate progress toward WHO 2030 goals.

5582

EVALUATION OF HIGHER SEROLOGIC THRESHOLD FOR STOPPING MASS DRUG ADMINISTRATION IN ONCHOCERCIASIS ELIMINATION IN THE TUKUYU FOCUS, TANZANIA

Rebecca J. Chancey[1], Andreas Nshala[1], Akili Kalinga[2], E. Scott Elder[1], Paul Maritine Hayuma[2], Clara Jones[3], Erick Mgina[2], Oscar Kaitaba[3], Ben Masiira[4], Thomson Lakwo[4], George Kabona[3], Paul T. Cantey[1]

[1]CDC, Atlanta, GA, United States, [2]National Institute for Medical Research, Dar es Salaam, Tanzania, United Republic of, [3]Neglected Tropical Disease Program, Dodoma, Tanzania, United Republic of, [4]African Field Epidemiology Network, Kampala, Uganda

Mass drug administration (MDA) with ivermectin is the primary elimination strategy for onchocerciasis. MDA may be stopped if programs meet World Health Organization (WHO) entomological and seroprevalence (<0.1%) criteria, the latter of which is challenging and may be lower than necessary. A multi-year study to evaluate a serologic threshold of ≤2% for stopping MDA was conducted in Tukuyu focus, Tanzania. If seroprevalence was ≤2% and WHO entomological criteria were met, then MDA would be stopped, and annual follow-up would begin. We present baseline and year 1 follow-up results. In the baseline study, 2000 children 5–9 years old were randomly sampled in villages stratified by prevalence concurrent with an entomologic study. Additional 1st-line villages were added so that one associated with each breeding site was evaluated, but the results were excluded from the overall seroprevalence. In year 1 of follow-up, 800 children 5–9 years old were sampled in eight 1st-line villages and entomologic evaluation was repeated. After parental permission and child assent were obtained, questionnaires were administered, and dried blood spots (DBS) were collected. DBS were analysed by Ov16 enzyme-linked immunosorbent assay (ELISA) and Ov16 rapid diagnostic tests (RDT). Entomology results will be presented separately. In the baseline study, 2,561 children (51% male) were enrolled: 2,070 children (52% male) from randomly selected villages and 491 children (47% male) from purposively selected villages. The seroprevalence among the children in randomly selected villages was 1.21% by ELISA and 0.045% by RDT. In 1st-line villages, the seroprevalence was 0.61% by ELISA and 0% by RDT. In year 1 follow-up, 809 children (47% male) were sampled with seroprevalence 0.12% by RDT; ELISA results are pending. Demonstrating that MDA can be stopped at a threshold >0.1% is important to help countries achieve WHO 2030 roadmap goals. New diagnostics are being developed assuming that 1% will be the threshold. Serologic data presented here are consistent with the hypothesis that it is safe to stop MDA at a higher threshold, but more follow-up data are needed to demonstrate this.

5583

PROVIDING EVIDENCE ON THE STATUS OF TRANSMISSION OF ONCHOCERCIASIS IN 5 COUNTIES IN LIBERIA

Sonnie Ziama Gbewo[1], Chris Tealeh[2], Louise Hamill[3]

[1]Ministry of Health, Paynesville, Liberia, [2]Sightsavers, Monrovia, Liberia, [3]Sightsavers International, Haywards Health, London, United Kingdom

In 2018, the Ministry of Health-Liberia conducted its first programmatic Ov16 serological survey (pre-stop) to provide evidence on the status of transmission of onchocerciasis in the Southwest Regions (five counties; Bomi, Cape Mount, Margibi, Grand Bassa and River Cess). These five counties had received 14th years of MDA with ivermectin. Specifically, the objective was to determine the village level sero-prevalence of Ov16 in children 5-9 years old. A target convenience sample size of 100 children from each of 30 frontline communities within 5km of a blackfly breeding site or onchocerciasis river basin was selected in line with WHO onchocerciasis technical subcommittee guidelines. All enrolled consented children were tested for Ov16 using RDT in the field, and DBS were collected to allow subsequent ELISA testing. Of children testing negative for rapid test, 10% was randomly selected for confirmatory testing using SD Ov16 ELISA (Abbott, South Korea). Out of the target sample size of 3,000, a sample size of 2,468 was achieved. 91 of these children tested positive for Ov16 via RDT in the field. Out of 30 communities tested with RDT, 19 communities had positive cases while 11 reported all negative tests. The overall seroprevalence rate of 3.7% (91/2432) was found in five counties (Bomi, Grand Bassa, Grand Cape Mount, Margibi and Rivercess) with rate of 3.7% (21/572) in onchocerciasis endemic county only. In addition, rates of 3.2% (10/314), 0.5% (3/595), 0.7% (3/455) was observed in onchocerciasis and lymphatic Filariasis co-endemic counties with a high rate of 10.9% (54/496), respectively. According to WHO, to proceed to a full stop MDA survey, the prevalence threshold for IUs to “pass” pre-stop is <2%. We realized only two counties have crossed this benchmark, onchocerciasis transmission is still ongoing in one of the counties (Rivercess) and there is a need for support to conduct similar testing in the remaining 10 counties.

5584

HIGH PREVALENCE OF LOA LOA AND MANSONELLA PERSTANS IN NORTHERN GABON

Luccheri Ndong Akomezoghe, Noé Patrick M'Bondoukwé, Denise Patricia Mawili Mboumba, Jacques Mari Ndong Ngomo, Bridy Chesly Moutombi Ditombi, Hadry Roger Sibi Matotou, Valentin Migueba, Marielle Karine Bouyou-Akotet
Université des Sciences de la Santé, Owendo, Gabon

Loa loa infection is endemic in central African countries, such as Gabon, and in West Africa. In regions where onchocerciasis is co-endemic with loasis, L. loa infection represents a major obstacle to control of onchocerciasis. Subjects with Loa loa hypermicrofilaremia more than 8000 mf/mL are at risk of developing severe and/or serious adverse effects following treatment with ivermectin. In 2011, the distribution of filariasis due to L. loa and Mansonella perstans has been carried out in Gabon. Ten years later, we are interested in evaluating the evolution of the prevalence of these filariasis in a northern of Gabon. Participants were recruited in northern Gabon, from November 2021 to April 2022. Venous blood was collected in an EDTA tube for microfilaria detection using blood direct examination and leukoconcentration techniques. Sociodemographics, hematological and parasitological parameters have been recorded. During the study, 1342 participants over the age of 18 were screened for the L. loa and M. perstans detection in 36 villages. Prevalences were 30.0% (403/1342) for L. loa, 4.9% (66/1342) for M. perstans and 1.9% (25/1342) for the coinfection. A hypermicrofilaremia was found in 12.9% (52/403) of participants with L. loa infection. Age and gender were risk factors associated with Loa loa and M. perstans microfilariae carriage: men were twice more infected than women (OR = 1.9, 95% CI [1.49 - 2.41] ; pγ0.001) and older people (>55) (p=0.0012, OR = 1.48, IC95% [1.16; 1.90]) than age group varying between regarding loiasis. For M. perstans, same findings were observed for M. perstans for men (OR = 2.4, 95% CI [1.40; 4.20]; p<0.001) and older people (p= 0.003, OR = 2.15, IC95% [1.25; 3.74]). The filariasis distribution according to villages differed significantly for L. loa (p=0.0034) and M. perstans (p<0.001). In conclusion, the prevalence of L. loa in northern Gabon is higher than the global rate of 22.4% reported, 10 years ago unlike M. perstans, found two times less than the 10.0% of 10 years ago. There was heterogeneity between villages.

5585

DIROFILARIA SP. HONG KONG AND BRUGIA SP. SRI LANKAN GENOTYPE ARE THE PRIMARY CAUSES OF FILARIAL INFECTION IN DOGS IN SRI LANKA

Ushani Atapattu, Anson V. Koehler, Lucas G. Huggins, Anke Wiethoelter, Rebecca J. Traub, Vito Colella
University of Melbourne, Parkville, Australia

The mosquito-borne Dirofilaria repens, Brugia malayi, B. ceylonensis, and flea- and louse-borne Acanthocheilonema reconditum are historically known to be endemic among dogs in Sri Lanka. Despite this, limited information on the prevalence, diversity, and predictors of filarial infections in dogs in Sri Lanka have resulted in suboptimal control and prevention of these parasites, some of which are known to be zoonotic. To address this, whole blood and metadata were collected and analysed from 423 pet dogs across three geo-climatic zones within Sri Lanka. Blood samples were screened using the Modified Knott's Test (MKT) and PCR followed by Sanger sequencing. Multivariable logistic regression models were used to assess predictors for canine filarial infections. Two novel genotypes, Dirofilaria sp. Hong Kong (Dirofilaria HK) and Brugia sp. Sri Lankan genotypes were identified infecting dogs. The overall prevalence of filarial infection in pet dogs by PCR was 37.1% (95% CI 32.5 - 41.9%, n=157), compared to 18.6% (95% CI 15 - 22.6%, n=78) detected using the MKT. More than 80% of filarial-positive dogs were infected with Dirofilaria HK, while the remaining dogs were infected with Brugia sp. SL genotype. Increasing age (p<0.001) and residing in the low-country wet zone (p<0.001), which include regions that were endemic for human filariasis in Sri Lanka were associated with filarial infections in the study subjects. No clear pathognomonic signs for filarial infection were identified, indicating that dogs may act as reservoirs for these potentially zoonotic pathogens. Given the morphologic similarity of Dirofilaria HK and Brugia sp. Sri Lankan microfilariae with those of D. repens and B. malayi, respectively, it is likely that these species have been misidentified in the past. Therefore, it is necessary to take measures to prevent and control canine filarial infections to safeguard both canine and human health.

DIFFERENCES IN VACCINE-SPECIFIC RESPONSES BETWEEN URBAN AND RURAL ENVIRONMENTS AND MEDIATORS OF THESE DIFFERENCES AMONG UGANDAN ADOLESCENTS: THE POPVAC TRIALS

Agnes Natukunda[1], Ludoviko Zirimenya[1], Gyaviira Nkurunungi[1], Jacent Nassuuna[1], Emily L. Webb[2], Alison M. Elliott[1]
[1]MRC/UVRI & LSHTM Uganda Research Unit, Kampala, Uganda, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

Geographic and urban-rural variation in vaccine immune responses has been observed. Helminth and malaria infections, more common in settings where immune responses are impaired, have been implicated due to their immunomodulatory roles. We aimed to assess urban-rural differences in vaccine responses in Uganda and to identify mediators (with a focus on parasites) of these differences. We conducted three linked randomised trials: POPVAC A assessed effects of intensive vs standard praziquantel treatment on vaccine responses in a high schistosomiasis burden rural area, POPVAC B effects of intermittent preventive malaria treatment vs placebo in a high malaria burden rural area, and POPVAC C effects of BCG re-vaccination in a low infection urban area. BCG, yellow fever (YF-17D), oral typhoid (Ty21a), HPV and tetanus/diphtheria (Td) vaccines were administered to the same schedule in each trial. Outcomes were BCG-specific IFN-γ 8 weeks post-BCG vaccination and antibody responses to vaccine-specific antigens 4 weeks post-vaccination (YF-17D, S. typhi lipopolysaccharide (LPS), HPV) and 24 weeks post-Td. Schistosomiasis and malaria infections at baseline were determined using CAA assay and PCR, respectively. Regression analysis adjusting for age and sex assessed differences in responses between studies, with comparisons restricted to standard treatment and placebo arms for POPVAC A and B, respectively. Vaccine responses from 239 (POPVAC A), 171 (B), and 151 (C) participants were compared. There were differences in responses between settings for all vaccines: tetanus IgG (p=0.004), yellow fever titers (p=0.005) and oral typhoid IgG (p<0.001) were lower in both rural settings compared to urban. However, diphtheria IgG (p<0.001) was lowest in POPVAC A (high schistosomiasis) but highest in POPVAC B (high malaria) and BCG-specific IFN-γ differences varied over time with POPVAC A participants having lower peak responses but higher waning responses. Differences were observed for all vaccines; causal mediation analysis to quantify the contribution of parasitic infections to these differences will be presented at the meeting.

HOW DOES THE PROPORTION OF NEVER TREATMENT INFLUENCE THE SUCCESS OF MASS DRUG ADMINISTRATION PROGRAMMES FOR THE ELIMINATION OF LYMPHATIC FILARIASIS?

Klodeta Kura[1], **Wilma A. Stolk**[2], María-Gloria Basáñez[1], Benjamin S. Collyer[1], Sake J. de Vlas[2], Peter J. Diggle[3], Katherine M. Gass[4], Matthew Graham[5], T. Deirdre Hollingsworth[5], Jonathan D. King[6], Alison Krentel[7], Roy M. Anderson[1], Luc E. Coffeng[2]
[1]Department of Infectious Disease Epidemiology, School of Public Health, Imperial College London, London, United Kingdom, [2]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [3]CHICAS, Lancaster Medical School, Lancaster University,, Lancaster, United Kingdom, [4]Neglected Tropical Diseases Support Center, Task Force for Global Health, Decatur, GA, United States, [5]Big Data Institute, University

of Oxford, Oxford, United Kingdom, [6]World Health Organization, Geneva, Switzerland, [7]School of Epidemiology and Public Health, University of Ottawa, Ottawa, ON, Canada

Mass drug administration (MDA) is the cornerstone for the elimination of lymphatic filariasis (LF). An important driver for achieving this goal is the proportion of the population that never received treatment (NT). We employ two individual-based stochastic transmission models to assess the maximum level of NT with which the 1% microfilaria (mf) prevalence threshold can still be achieved under different scenarios for coverage of annual MDA, the drug combination used and transmission settings. For Anopheles-transmission settings, we find that treating 80% of the eligible population annually with ivermectin + albendazole (IA) can achieve the target within 10 years of annual treatment when baseline mf prevalence is 10%, as long as NT is below 10%. Higher proportions of NT are acceptable when more efficacious treatment regimens are used. For Culex-transmission settings with a low (5%) baseline mf prevalence and DA or IDA treatment, elimination can be reached if treatment coverage among eligibles is 80% or higher. For 10% baseline mf prevalence, the target can be achieved when the annual coverage is 80% and NT is 15% or lower. Higher infection prevalence or levels of NT would make achieving the target more difficult. The proportion of people never treated in MDA programmes for LF can strongly influence the achievement of elimination and the impact of NT is greater in high transmission areas. This study provides policy-relevant quantitative insights into what levels of NT may be acceptable to achieve elimination in different epidemiological and programmatic settings. In addition, our results provide a starting point for further development of criteria for the evaluation of NT.

5588

ASSESSING IMPACT OF IVERMECTIN AND ALBENDAZOLE MASS DRUG ADMINISTRATION ON TRANSMISSION OF LYMPHATIC FILARIASIS IN 24 DISTRICTS IN SENEGAL

Ngayo Sy[1], Ernest Mensah[2], Rose Monteil[3], Babacar Banda Diallo[3], Babacar Guèye[1], Achille Kabore[4]

[1]Ministry of Health and Social Action, PNEFO, Dakar, Senegal, [2]FHI 360, Accra, Ghana, [3]FHI 360, Dakar, Senegal, [4]FHI 360, Washington, DC, United States

Mapping of lymphatic filariasis was conducted in Senegal in 2003-2010 and found 51 of 79 districts endemic with Wuchereria bancrofti parasite antigenemia prevalence in sentinel sites of 1.0 to 78%. Annual mass drug administration (MDA) with ivermectin and albendazole was initiated in 2007. In 2018-2021, 17 districts passed transmission assessment survey (TAS) for the first time and have since stopped MDA. In 2021, 24 districts with an average baseline antigenemia prevalence of 14% became eligible for pre-transmission assessment survey (pre-TAS) to assess impact of MDA on prevalence of W. bancrofti infection after achieving the required five effective annual MDA rounds with at least 80% program coverage. In the pre-TAS conducted in 2021, 300-350 persons over 5 years old were assessed for W. bancrofti antigenaemia in sentinel and spot-check sites in each district. W. bancrofti antigenaemia prevalence was fund to have reduced from 1-78% in sentinel sites and 3-32% in spot-check sites to ≤ 0.3% in all 24 districts. Subsequently, transmission assessment surveys were conducted in 24 districts in 2022 to determine if transmission of the parasite has been interrupted and MDA could be stopped. The 24 districts were grouped into 19 evaluation units (EU) based on similarity of baseline prevalence, ecological factors, proximity and population for the TAS. Between 1320 and 1548 randomly selected children in grades 1 and 2 (as proxy for 6-7-year-olds) were assessed for antigenaemia in 30 randomly selected clusters (primary schools) in each EU. In both pre-TAS and TAS, filarial test strips (FTS) were used to detect presence of W. bancrofti antigens in 75µl of finger stick blood. Two out of 19 EU recorded one positive case, significantly below the critical cut-off value of 18 positives, no positive case was found in the remaining 17 EU indicating that parasite transmission has been interrupted in all EU. MDA has consequently been stopped in the 24 districts and they are currently under post-treatment surveillance.

SIGNIFICANT ACHIEVEMENTS IN LYMPHATIC FILARIASIS ELIMINATION IN NORTHWESTERN ETHIOPIA

Geremew Haileyesus[1], Mohammed Hassen[1], Aderajew Mohammed[1], Tekola Endeshaw[1], Yewondwossen Bitew[1], Tewodros Seid[1], Desalegn Jemberie[1], Abebual Yilak[1], Worku Mamo[1], Fetene Mihretu[1], Gedefaw Ayenew[1], Mitiku Adugna[1], Mossie Tamiru[2], Fikre Seife[2], Anley Haile[1], Emily Griswold[3], Jenna E. Coalson[3], Gregory S. Noland[3], Frank O. Richards, Jr.[3], Zerihun Tadesse[1]

[1]The Carter Center, Addis Ababa, Ethiopia, [2]Federal Ministry of Health, Addis Ababa, Ethiopia, [3]The Carter Center, Atlanta, GA, United States

Lymphatic filariasis (LF) was historically endemic in 104 (9%) of Ethiopia's districts. Efforts to eliminate LF as a public health problem started in three districts of West Gondar zone in Northwestern Ethiopia in 2012 with integrated annual mass administration (MDA) of ivermectin and albendazole for onchocerciasis and LF. Following the WHO guidelines, after five rounds of effective mass treatment with >65% epidemiological coverage and successful Pre-transmission assessment surveys, the first Transmission Assessment Survey (TAS-1) was conducted in 2016 in the three districts with total population of about 330,000 at the time: Metema, Gendewuha, and Quara, which were independent, contiguous implementation units combined into one evaluation unit. The TAS-1 tested 1899 children aged 6 and 7 sampled from randomly selected communities, only 3 of whom (0.2%) were positive for circulating filarial antigen (CFA), which was less than the critical cut-off of 18. Following the halt of MDA for LF and onchocerciasis in 2017, LF post-treatment surveillance surveys found zero CFA-positive children among 1877 tested in the second of the TAS series, TAS-2, in 2019. Finally, only 1 (0.06%) CFA-positive child (a 7-year-old lifelong resident) was found among 1611 children tested in the final TAS-3 in November 2022. This indicates that over 360,000 people are no longer at risk for LF transmission in these three districts of northwestern Ethiopia. Continued post-"elimination" surveillance should continue until surrounding areas also interrupt transmission as migration from endemic areas is common. The successful completion of the TAS series is the first of its kind in Ethiopia and has motivated other parts of the country to achieve LF elimination success.

NATIONWIDE RE-MAPPING SURVEY FOR LYMPHATIC FILARIASIS ELIMINATION IN THE DOMINICAN REPUBLIC

Karen E.S. Hamre[1], Luccène Désir[1], V. Madsen Beau de Rochars[2], Keyla Ureña[3], Julio Alexis Batista[3], Angelita Méndez Florian[3], Luisa A. Feliz Cuevas[3], Carmen Cuello Montilla[3], Gregory S. Noland[1], Manuel Gonzales[3]

[1]The Carter Center, Atlanta, GA, United States, [2]University of Florida, Gainesville, FL, United States, [3]Ministerio de Salud Pública, Santo Domingo, Dominican Republic

The Dominican Republic aims to eliminate lymphatic filariasis (LF) as a public health problem and demonstrate elimination of transmission. Nationwide baseline mapping (1999-2003, 2007) using lot-quality assurance sampling for LF identified three endemic foci in need of mass drug administration (MDA). These foci are currently in post-treatment surveillance. Recognizing the gap since baseline mapping, the Ministry of Health (MSP) conducted an LF re-mapping survey in 2022 to confirm that active transmission does not exist in historically non-endemic areas. A nationwide cross-sectional household (HH) survey was conducted in 40 provincial and health area directorate evaluation units (EU). Within each EU, 30 communities were randomly sampled; within each community, 16 HHs were selected where one member ≥6 years of age was asked to participate. A blood sample was tested for circulating filarial antigen (CFA) by Filariasis Test Strip (FTS). The prevalence and spatial distribution of LF antigenemia and LF morbidity was evaluated. Case investigations, treatment, and night blood sample collection were conducted per MSP guidelines. Provisionally, 19 of 15379 participants tested were CFA-positive (age range: 21-68 years). All 14 of

those tested to date for microfilaremia by night blood sample were negative; follow-up testing is pending for 5 individuals. Lymphedema was self-reported by 166 of 15358 adults and hydrocele by 19 of 6001 adult males. Weighted CFA prevalence estimates by EU ranged from 0-3.6%, with five EUs having an upper confidence limit &gt2%, the proposed threshold for starting MDA in re-mapping assessments. Additional investigation is needed to determine whether these results represent evidence of past or current transmission and if interventions such as MDA or focal MDA are needed. This re-mapping approach contributes to the conversation and possible methodologies for establishing verification of elimination of LF transmission.

MOLECULAR EPIDEMIOLOGY OF CIRCULATING DIROFILARIA IMMITIS AND D. REPENS IN CULICIDAE MOSQUITOES FROM REYNOSA, TAMAULIPAS

Enrique Lopez-NegreteMata[1], Javier Alfonso Garza-Hernandez[2], Carlos Arturo Rodríguez-Alarcón[2], Luis Daniel Garcia-Muñoz[3], Miguel Angel Reyes-Lopez[1], Stephanie Viridiana Laredo-Tiscareño[2], Isela Quintero-Zapata[4], Fatima Lizeth Gandarilla-Pacheco[4], **Erick de Jesus de Luna-Santillana**[1]

[1]Instituto Politecnico Nacional, Reynosa, Mexico, [2]Universidad Autonoma de Ciudad Juarez, Ciudad Juarez, Chihuahua, Mexico, [3]Veterinaria Garia, Reynosa, Mexico, [4]Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico

Dirofilariasis is a disease caused by a nematode of the genus Dirofilaria, as D. immitis and D. repens. This disease affects both dogs and other vertebrate hosts and involves the parasite lodging in the heart or other organs. The parasite is transmitted to another host by mosquito bites. The aim of this study was to assess the prevalence of D. immitis and D. repens in dogs and mosquitoes in Reynosa, Tamaulipas, Mexico. An assay was performed to identify the presence of Dirofilaria in dog blood samples and mosquito abdomen to determine the prevalence of both filaria's species. For the capture of mosquitoes, 25 colonies distributed in Reynosa city were sampled using Sentinel traps, whereas for dog blood samples we had the support of veterinaries that treat dogs from different parts of the city and adjacent areas. An nested PCR assay was performed for the detection of species of Dirofilaria. In addition, a second PCR assay was performed to determine the mosquito species that fed on human blood to determine a possible zoonosis. A 2.64% prevalence of D. immitis infection was found in dogs from 188 samples tested, while no presence of the parasite was found in female mosquitoes from 250 specimens. Four of the five dogs positive for the presence of Dirofilaria spp. belonged to another US cities whose neighboring areas have a higher prevalence, specifically localized in the Rio Grande Valley; only one was found to be from Reynosa. Two hundred fifty engorged Culicidae mosquitoes were captured, of which 98.5% were fed with human blood. The mosquito's species with the highest population density are Aedes aegypti and Culex quinquefasciatus and both species are competent as a vector for Dirofilaria. All samples of Ae. aegypti and most samples of Cx. quinquefasciatus reveals at least having fed on humans' blood, making this finding a possible risk of Dirofilaria zoonosis towards humans in the city of Reynosa. Another culicid species was identified were An quadrimaculatus (not showing human blood feeding), and in the case of Cx. erraticus and Ae. epactius, not exist too much information regarding their vector competence for Dirofilaria.

GENETIC DIVERSITY WITH THE EMERGING ZOONOSIS OF AN ONCHOCERCA SPECIES OF HUMAN POPULATIONS IN TARABA STATE, NIGERIA

Iliya S. Ndams[1], Danlami E. Akfyi[1], Ishaya H. Nock[1], Gloria D. Chetchet[1], Alfons Renz[2]

[1]Ahmad Bello University Zaria, Zaria, Nigeria, [2]Institute of Ecology and Evolution, University of Tubinen, Tubingen, Germany

A better understanding of Onchocerca population genetic processes in a specific biogeography is needed to support the onchocerciasis elimination goals. The study investigated the genetic diversity of Onchocerca microfilariae using a fragment of 16S rDNA genes in some onchocerciasis endemic communities of Taraba State, Nigeria. The investigation was in eight selected communities comprising six endemic communities with a high prevalence of infection despite receiving mass drug administration with ivermectin for between 10 and 16 years of annual treatments and two non-endemic areas. Skin snips were obtained from 321 consenting participants after community engagement and who were more than five years of age and had resided within the communities for more than ten years or since birth. DNA was extracted from the microfilariae that emerged from the normal saline and the residual skin snip samples and preserved in RNAlater® in a 1.5 ml centrifuge tubes. A Polymerase Chain Reaction (PCR) amplification with generic and species-specific primers targeting the 16S gene of the DNA extracted. The PCR product was eluded and cleaned for sequencing, while the resultant sequences were analysed to identify the Onchocerca species. The multiple sequence alignment protocol showed the distinct diversity of two sequences G49_O.v. Gashaka and Y02_O.v. Yorro samples with 100% similarity that matched sequences of O. volvulus from Cameroon that has been deposited in the GenBank, indicating the emergence of a new polymorphic strain of O. volvulus species. Similarly, two O. ochengi sequences isolated from human samples, O. ochengi G44_Gashaka; O. ochengi G01_Gashaka and O. ochengi Y04_Yorro, matched with an O. ochengi sequence in the GenBank from Cameroon and is being reported from the study communities for the first. The study has identified O. volvulus as the cause of onchocerciasis and O. ochengi with the potentials of an emerging zoonotic onchocerciasis in the cattle (animal)-Simulium(vector)- human interface characteristic of the communities.

BENCHMARKING AN ACCESSIBLE METHOD FOR GENERATING COMPLETE GENOMES FROM PARASITIC NEMATODES

Kaylee S. Herzog, Joseph R. Fauver

University of Nebraska Medical Center, Omaha, NE, United States

Parasitic nematodes, including filarial worms and soil-transmitted helminths, are etiological agents of both acute and chronic disease. Recent technological and methodological advances in genomics have revolutionized the study and treatment of parasitic nematodes. Though remarkably impactful, these advances have also underscored a critical issue: Generating short-read DNA sequence data (and building and maintaining the infrastructure needed to do so) is expensive, making genomic resources largely inaccessible. The Oxford Nanopore Technologies (ONT) MinION is an inexpensive and portable next-generation sequencing platform capable of producing ultra-long DNA sequences ideal for whole genome assemblies; however, poor read level accuracy has hindered widespread adoption of the platform. Recent advances in ONT chemistries have produced more accurate and reliable read level data. To determine if whole genome assemblies using only ONT data reflect current gold standard hybrid assemblies, we generated complete genome assemblies for the parasitic nematodes Brugia malayi and Trichuris trichiura using only ONT MinION Q20+ sequence data. We compared each ONT MinION assembly to reference genomes generated using a hybrid assembly approach, and assessed contiguity, completeness, and accuracy using QUAST, BUSCO, and MUMmer4, respectively. For B. malayi, we generated an 88 gigabase (Gb) assembly in 85 contigs that covers 99.8% of the reference genome. The two assemblies both contain >99% of BUSCOs known for the phylum Nematoda and are >99.9% identical when considering only single base pair (bp) mismatches. For T. trichiura, we generated a 71 Gb assembly in 158 contigs that covers 99.4% of the reference genome. The two assemblies both contain ~46% of BUSCOs known for the Nematoda and are >97.8% identical when considering only single bp mismatches. These results highlight the ONT MinION and its Q20+ platform update as an accessible stand-alone alternative to traditional sequencing approaches for the generation of whole genome assemblies for parasitic nematodes.

BMA-LAD-2 AS A NOVEL ANTIBODY TARGET FOR THE TREATMENT OF LYMPHATIC FILARIASIS

Allison Segard, William Tolbert, Christopher Broder, Marzena Pazgier, Edward Mitre

Uniformed Services University, Bethesda, MD, United States

Efforts to control the global burden of Lymphatic Filariasis focus primarily on Mass Drug Administration (MDA). While highly effective against microfilariae, current MDA regimens have little to modest effects on adult worms. Thus, MDA typically has to be repeated over several years. Additionally, the most efficacious MDA regimen is contraindicated in areas co-endemic with Loa loa and Onchocerca volvulus infections due to adverse effects caused by rapid killing of microfilariae. The long-term goal of this study is to develop a novel macrofilaricidal agent that would allow for fewer MDA treatments and safe use in areas with L. loa and O. volvulus. Previously, we showed that Bma-LAD-2, an intestinal protein in Brugia malayi likely involved in tight junction formation, is essential for adult worm fecundity, metabolism, and motility. In this study, we are testing whether antibodies targeting Bma-LAD-2 can function as macrofilaricidal agents. We have recombinantly expressed a soluble form of the outer binding Ig domains of Bma-LAD-2 (Bma-LAD-2 Ig1-4) and have created stably transfected HEK293 cells expressing full-length transmembrane Bma-LAD-2 protein. Bma-LAD-2 transfected cells were found to have higher electrical resistance across a monolayer than non-transfected HEK cells by TransEpithelial Electrical Resistance (TEER) assay. Addition of polyclonal rabbit antibodies against Bma-LAD-2¬ Ig1-4 to the transfected cell line decreased TEER values to those of non-transfected cells. Finally, we have found that anti-SARS-CoV-2 antibodies in human sera cultured with adult B.malayi worms were still functional after ingestion by adult worms. Together, these results suggest that adult filarial worms ingest antibodies into their intestinal tracts, and that antibodies against Bma-LAD-2 have the potential to interrupt intestinal tight junctions of filariae. We are currently working to determine the effect of treating adult B.malayi worms with anti-Bma-LAD-2 antibody. It is possible that if the binding domains of the Bma-LAD-2 are conserved across filarial species, these antibodies could be used as a pan-filarial macrofilaricide.

IMPACT OF WUCHERERIA BANCROFTI INFECTION ON CERVICAL MUCOSAL IMMUNITY OF WOMEN IN LINDI, TANZANIA

Maureen Mosoba[1], Thomas F. Marandu[2], Jacklina Mhidze[2], Sacha E. Horn[3], Winfrida John[4], Abdallah Ngenya[4], Upendo J. Mwingira[4], Agatha D. Urio[2], Nhamo Chiwarengo[5], Christof Geldmacher[3], Manuel Ritter[6], Michael Hölscher[3], Achim Hoerauf[6], Akili Kalinga[4], Lucas H. Maganga[2], Mkunde Chachage[2], **Inge Kroidl**[3]

[1]Center for International Health, Munich, Germany, [2]National Institute for Medical Research-Mbeya Medical Research Center, Mbeya, Tanzania, United Republic of, [3]Medical Center of the University of Munich (LMU), Munich, Germany, [4]National Institute for Medical Research-Head Quarter, Dar es Salaam, Tanzania, United Republic of, [5]National Institute for Medical Research-Mbeya Medical Research Center, Dar es Salaam, Tanzania, United Republic of, [6]Institute of Medical Microbiology, Immunology and Parasitology, Bonn, Germany

Lymphatic filariasis is a mosquito-transmitted parasitic infection in tropical regions. Our group had previously described an increased HIV incidence in individuals infected with Wuchereria bancrofti in Southwest Tanzania. Most HIV transmissions in sub-Saharan Africa occur through heterosexual contact. However, W. bancrofti is not known to cause lesions or ulcers in the genital mucosa as other diseases are known to do. The aim of this work is to analyze cervical mucosal T cell phenotypes in women infected with W. bancrofti and compare the results with uninfected women from the same area. Women (aged 18-45) from the Lindi region of Tanzania were screened for W. bancrofti infection using filarial test strips (FTS, Abbott). HIV status was determined using HIV 1/2 3.0 (Standard Diagnostics Inc) and positive results were confirmed using Uni-Gold Recombigen HIV - ½ (Trinity Biotech). From each woman, a cervical mucosal sample was taken for T cell phenotyping and Pap smear and HPV typing were performed. Samples were stained for flow cytometric measurement of activation, cell lineage and maturation markers, as well as HIV receptor and facilitator markers (HLA-DR, CD38, Vdelta2, CD45, CD27, CD25, FoxP3, CCR5, beta7) on CD4 and CD8 T cells. Between October and December 2020, 38 HIV-uninfected female study participants (mean age 24.6 years) were recruited; 26 of them were infected with W. bancrofti. None had abnormalities in the Pap smear and 12 women were found to have high-risk (HR) HPV types. Two of 12 filarial-uninfected women had HR HPV (17%) detected in the mucosal sample versus 10/25 (40%) HR HPV in W. bancrofti infected women (p=0.2). An increased expression of HIV co-receptor CCR5 on memory CD4 T cells as well as increased number of gamma-delta2+ T cells (p=0.0042) were found in the cervical mucosa of W. bancrofti-infected women. The systemic infection with W. bancrofti infection, which, unlike other helminthic infections, has no known genital lesions, was associated with T cell changes of the cervical mucosa in a small number of women. We additionally found an augmented prevalence of HPV in W. bancrofti infected women.

5596

EFFECTS OF WUCHERERIA BANCROFTI INFECTION ON CD4 T CELL RESPONSES TO SPECIFIC AND NON-SPECIFIC ANTIGENS

Jacklina Mhidze[1], Mkunde Chachage[2], Maureen Mosoba[1], Sacha Horn[3], Agatha Urio[1], Antelmo Haule[1], Nhamo Chiwerengo[1], Said Aboud[4], Lucas Maganga[1], Inge Kroidl[3], **Thomas F. Marandu**[2]

[1]National Institute for Medical Research -NIMR-MMRC, Mbeya, Tanzania, United Republic of, [2]University of Dar es Salaam / National Institute for Medical Research -NIMR-MMRC, Mbeya, Tanzania, United Republic of, [3]Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich (LMU), Munich, Germany, [4]National Institute for Medical Research -NIMR-Headquarters, Dar es Salaam, Tanzania, United Republic of

Lymphatic filariasis, primarily caused by Wuchereria bancrofti, is a mosquito-transmitted disease, which is affecting people living in tropical regions. Infection with W. bancrofti is associated with chronic inflammations that may cause lymphedema and hydroceles. The adult worm of W. bancrofti lives for many years in the human host and even without disfiguring consequences leads to modulation of the adaptive immune response. This study aims to determine whether chronic W. bancrofti infection affects CD4 T cell responses to specific and non-specific antigens. Blood samples were collected from 141 participants living in two W. bancrofti endemic regions in Tanzania: Kyela district in Mbeya region, n=106 and Lindi district, n=35. Samples were stimulated with the whole lysate of Mycobacterium tuberculosis (Mtb), Staphylococcus Enterotoxin B (SEB) or PBS (control) for 16 hours. The frequency of CD4 T cells responding to stimulation by secreting interferon gamma (IFN-γ) or interleukin 2 (IL-2) cytokines was measured by flow cytometry. W. bancrofti-infected individuals had significantly fewer Mtb specific IL-2 producing CD4 T cells compared to uninfected individuals (p =0.010), while IFN-γ responses to Mtb specific stimulation were comparable between W. bancrofti infected and uninfected individuals. Interestingly, W. bancrofti infection showed significant reduced frequencies of IFN-γ (p<0.0001) and IL2 (p<0.0001) CD4 T cells responses upon stimulation with SEB compared to uninfected individuals. Our findings show diminished CD4 T cell responses to SEB in W. bancrofti infected individuals. Stimulation with Mtb showed differences for only one cytokine, IL-2, otherwise comparable results between the infected and the control group. These results indicate that chronic infection with W. bancrofti suppresses CD4 T cell responses, most likely as part of the immune evasion strategy of the parasite. These reduced immune responses might have a deleterious impact on the capability of the host to fight other infections.

MULTIPLEXED HIGH THROUGHPUT POINT-OF-CARE BIOSENSING OF ONCHOCERCIASIS ANTIBODY MARKERS

Mallika Senthil[1], Sarah Ali[1], Balazs Kaszala[1], Dhruti Trivedi[1], Neda Rafat[1], Sukwan Handali[2], Sylvia A. Ossai[2], Evan W. Secor[2], Aniruddh Sarkar[1]

[1]Georgia Institute of Technology, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Neglected tropical diseases (NTDs) disproportionately affect marginalized populations, often in resource-poor settings. The critical lack of cost-effective diagnostic tests devices for NTDs was highlighted in WHO's 2021-2030 Road Map. Current serological tests for onchocerciasis, which aid diagnosis and are important for disease mapping and mass drug administration decisions, detect only one antigen-specific antibody, limiting their sensitivity and specificity. Here, we report inexpensive yet multiplexed and high-throughput optical and electronic biosensing methods for point-of-care (POC) detection of antibodies against several onchocerciasis antigens from a single drop of serum. The optical method uses enzymatic silver metallization on standard glass slides and a custom cellphone app that measures the optical readout. The electronic method uses similar assay chemistry, but on microelectrode chips and generates a direct electronic readout. Recombinant onchocerciasis antigens are immobilized using laser-cut polydimethylsiloxane microwells. After sample incubation with onchocerciasis-positive and control samples, a horseradish peroxidase labeled probe is added. Finally, silver substrates are added to generate silver metallization related to the measured biomarker concentration. To demonstrate the POC detection, onchocerciasis patient (n=56) and control (n=35) sera were measured for IgG4 against multiple antigens (FABP, OV-16, Ov33, OvMSA) from single drops (3µL) of diluted sera. Onchocerciasis+ samples exhibited dark metallization decreasing with serial dilution, while controls showed low metallization. These findings were cross-referenced against an FABP ELISA, which demonstrated similar results. Multiple logistic regression with the onchocerciasis antigens improved the diagnostic accuracy (AuROC>0.95), indicating the value of multiplexed detection. This inexpensive multiplexed POC diagnostic approach holds promise for onchocerciasis detection as well as other NTDs.

CYTOKINE IN UTERO PRIMING IS ASSOCIATED WITH DETRIMENTAL BIRTH OUTCOMES AND CHILD INFECTIONS

Ruth K. Nyakundi[1], Ronald K. Ottichilo[2], Thomas M. Kariuki[3], Jann Hau[4], Bernard Guyah[2], Dunstan Mukoko[5], Francis M. Mutuku[6], A. Desiree LaBeaud[7], Christopher L. King[8], Charles H. King[8], **Indu Malhotra**[8]

[1]Institute of Primate Research, Nairobi, Kenya, [2]School of Public Health and Development Studies, Maseno, Kenya, [3]Alliance for Accelerating Excellence in Science in Africa, Nairobi, Kenya, [4]University of Copenhagen, Copenhagen, Denmark, [5]Division of Vector Borne and Neglected Tropical Diseases, Nairobi, Kenya, [6]Technical University of Mombasa, Mombasa, Kenya, [7]Stanford University School of Medicine, Stanford, CA, United States, [8]Case Western Reserve University, Cleveland, OH, United States

Infections during pregnancy are associated with foetal immune imprinting that impacts birth outcomes and susceptibility to childhood infections. This study investigated how anti-parasitic cytokine profiles in newborns' cord blood mononuclear cells (CBMCs) relate to low birth weight (LBW) and childhood infection. A total of 311 Kenyan mothers were followed during pregnancy and were tested for parasitic infections at each ante-natal clinic visit. At delivery, cord blood was collected and newborns' cytokine responses to Plasmodium falciparum, S. hematobium, and W. bancrofti antigens were assessed. The baby's birth weight was also recorded. Infants were followed to 18 months of age and blood, urine and stool samples were collected at every visit and tested for parasitic infections. Cytokine profiles of each child were classified by principle component analysis and termed as positive or negative response. We observed a positive association between IL-10, TNF-a and Th-1 responses in babies born to mothers with maternal malaria infection but negative response in those born to mothers co-infected with malaria and helminths. LBW was associated with IL-5 and IL-10 sensitized babies but not with any maternal infection. We also observed increased risk of malaria infection in children whose CBMCs had a predominant Th-1 profile particularly IL-2. Childhood malaria was also associated with increased risk of having severe anaemia, hookworm infection and any co-infection. This study suggests that maternal sensitization of either Th-1 or Th-2 cytokine profiles may contribute to poor pregnancy outcomes and increased susceptibility to childhood infections. Additionally, differential imprinting trajectories in utero were associated with either mothers were mono- or co-infected.

5599

IMPACT AND COST EFFECTIVENESS OF ANNUAL VS. TWICE ANNUAL MASS DRUG ADMINISTRATION FOR ELIMINATION OF LYMPHATIC FILARIASIS AND CONTROL OF ON CHOCERCIASIS IN COTE D'IVOIRE

Betsy Abente[1], Ann Goldman[2], Benjamin Koudou[3], Olivier Kouadio[3], Jennifer Klenke[1], Peter Fischer[1], Gary Weil[1]

[1]Washington University in St. Louis, St. Louis, MO, United States, [2]George Washington Unviersity, Washington, DC, United States, [3]Centre Suisse de Recherches Scientifiques (CSRS), Abidijan, Côte D'Ivoire

Lymphatic filariasis (LF) and onchocerciasis (oncho) are coendemic in many parts of Cote d'Ivoire, and can cause severe economic and physical burdens on populations and health systems. Mass drug administration (MDA) of ivermectin and albendazole is a key intervention strategy to eliminate these diseases in Africa. While most country programs implement MDA annually, some have posited that a twice per year MDA may be more effective, potentially reducing the time to elimination. Despite these potential benefits, very few studies have examined the costs and program implications for switching to a semi-annual schedule. We compared the relative impact and cost effectiveness of annual versus twice-yearly MDA in the two districts Abengourou (1x MDA) and Akoupe (2x MDA) in south-eastern Côte d'Ivoire. The Ministry of Health and other implementing partners collected cost data associated with the inputs and activities needed to run MDA programs. Data was collected from January - December 2014 and used to project costs for the full 3-year study period. The annual financial costs were 20% higher for 2x/year MDA ($34,012USD vs. $22,839USD). One year after the third round of 1x and the fifth round of 2x MDA, the LF microfilaria (Mf) prevalence decreased from 8.4% to 2.5% in the 1x MDA area and from 8.1% to 2.3% in the 2x MDA area. The oncho skin Mf prevalence decreased from 22.7% to 8.4% and from 23.1% to 7.5% in these areas, respectively. In conclusion, 2x MDA was more costly but no more effective than annual MDA in this study. Based on these results, we recommend that country programs focus limited resources to conduct high quality annual MDA, in accordance with current WHO guidance.

INVESTIGATING KNOWLEDGE, ATTITUDES, AND PRACTICES OF HEALTH WORKERS ON THE MANAGEMENT OF FEMALE GENITAL SCHISTOSOMIASIS IN THE SOUTH REGION OF CAMEROON

Charlotte Njua Mbuh

Texila American University, Lusaka, Zambia

Schistosomiasis is an acute and chronic disease caused by parasitic worms that can take two main forms: intestinal or urogenital. If left untreated, the urogenital form can lead to female genital schistosomiasis (FGS) in women and girls; frequently resulting in severe reproductive health complications which are often misdiagnosed as sexually-transmitted infections. This study assessed healthcare workers' knowledge, attitudes and practices of the management of FGS in the South Region of Cameroon.Using quantitative research methods, a questionnaire was administered to 104 health workers from all levels in the health system (Health facility, district and Region) from all the 10 health districts of the South Region. Over half of the participants

had heard about FGS but very few had clinical knowledge that could enable them to diagnose, treat and prevent FGS. Most healthcare workers did not have any confidence in their ability to effectively manage cases. Healthcare workers in the South Region of Cameroon present significant gaps in knowledge about FGS especially when it comes to its diagnosis and treatment. There is a great need for the National NTDs programme to develop training manuals and organize capacity building workshops to equip healthcare workers with knowledge on FGS. Also, it is important to take advantage of other campaigns like free distribution of Ivermectin and Albendazole in communities against lymphatic filaria to educate the community on FGS and also improve upon water sanitation and hygiene to break the chain of transmission of the infection.

INVESTIGATING THE INFLUENCE OF PATHOGENIC LEPTOSPIRE SHEDDING BY RAT POPULATIONS ON HUMAN LEPTOSPIRA INCIDENCE IN SALVADOR, BRAZIL

Nirali Soni[1], Fábio N. Souza[2], Albert I. Ko[3], Elsio A. Wunder Jr[3], Michael Begon[4], Hussein Khalil[5], Daiana S. de Oliveira[6], Mitermayer G. Reis[6], Federico Costa[2], Emanuele Giorgi[1]

[1]Centre for Health Informatics, Computing, and Statistics, Lancaster University Medical School, Lancaster, United Kingdom, [2]Institute of Collective Health, Federal University of Bahia, Salvador, Brazil, [3]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [4]Department of Evolution, Ecology and Behaviour, University of Liverpool, Liverpool, United Kingdom, [5]Department of Wildlife, Fish and Environmental Studies, Swedish University of Agricultural Sciences, Umeå, Sweden, [6]Goncalo Moniz Institute, Oswaldo Cruz Foundation, Salvador, Brazil

Leptospirosis is a neglected zoonotic disease responsible for 1 million cases and 60,000 deaths annually, making it a major global health concern. Environmental distribution and concentration of pathogenic leptospires shed from rats are speculated to affect infection risk, but little is known on this association. Our objective was to investigate whether variations in leptospire shedding influence human Leptospira infection risk. We explored a novel approach of combining several statistical models to elucidate links between shedding and human Leptospira incidence, and the interplay with other risk factors. We performed eco-epidemiological studies in an urban slum environment in north-eastern Brazil. During 2013-14, we sampled roughly 500 Rattus norvegicus and quantified their shedding status and load, identified 700 unique points for R. norvegicus presence, and performed sequential surveys of residents to evaluate potential environmental and socioeconomic risk factors. We integrated data from these populations by building three statistical models. Models were built based on the Rattus norvegicus data for two outcomes: 1) shedding by individual rats and 2) the relative abundance of rats. The estimated 'total shedding' variable, obtained by multiplying the predictions from those two models, was used in a third model, as a risk factor for human Leptospira infection. Our results suggest that 'total shedding' by rat populations is an important risk factor for human infections (odds ratio [OR]=1.4; 95% confidence interval [CI]: 1.0-1.9), however, rat abundance, rather than shedding by individual rats, is the main driver of this association. Among factors pertaining to surroundings and the environment, infection risk was higher in areas with higher vegetative land cover i.e., more rural areas (OR=2.1; 95% CI: 1.1-3.9), and when rainfall entered the house (OR=1.9; 95% CI: 1.4-2.6). Effective prevention strategies will require control of the reservoir population in addition to addressing the structural features of slum settlements that promote transmission.

5602

MAINTAINING ELIMINATION OF TRACHOMA AS A PUBLIC HEALTH PROBLEM: POST-VALIDATION SURVEILLANCE PLANS IN VALIDATED COUNTRIES

Stephanie Palmer[1], Shoa Moosavi[2], Aryc W. Mosher[3], Anna Phillips[1], Achille Kabore[1]

[1]FHI 360, Washington, DC, DC, United States, [2]Georgetown University, Washington, DC, DC, United States, [3]USAID, Atlanta, GA, United States

Trachoma is targeted for global elimination as a public health problem by 2030. Repeated infections with Chlamydia trachomatis lead to inner eyelid scarring, causing the eyelashes to turn in and rub the cornea (trachomatous trichiasis, or TT) which can lead to blindness. The WHO-endorsed SAFE strategy (Surgery, Antibiotics, Facial cleanliness and Environmental improvement) is used to eliminate trachoma. To date, 15 countries have been validated by WHO as having eliminated trachoma. The epidemiological targets for validation are: trachomatous inflammation – follicular (TF) <5% among children 1-9 years and TT <0.2% in adults 15 and above in all districts. National Program submit dossiers to WHO to be validated. In these dossiers, plans to conduct post-validation surveillance (PVS) are described. We conducted a literature review to understand the organic landscape of PVS plans and activities. A search was conducted using the PubMed and Google Scholar databases using the terms "trachoma" and "post-validation surveillance." A Google search using "trachoma elimination dossiers" and country names was conducted. Abstracts were reviewed, and elimination dossiers, documents describing programmatic plans, or operations research on PVS were retained. Three dossiers were found (Ghana, Iran and Mexico). Programmatic documents with PVS plans were available from Oman and Morocco; a peer-reviewed publication was available for The Gambia. All countries plan to use a passive surveillance approach (case reporting via health information systems), though populations targeted and methods vary. Four countries also had an active surveillance approach: sentinel sites, contact investigations, or periodic surveys. All countries rely on clinical indicators; one country is considering syndromic and biological indicators. Two countries (Ghana and Morocco) have conducted operations research on PVS using clinical and biological indicators. In these, clinical signs remained under the elimination threshold. Age-adjusted seroprevalence varied by study site but seroconversion rates were low. Where detected, current infection prevalence was low.

5603

INTEGRATED SURVEILLANCE FOR LYMPHATIC FILARIASIS, VISCERAL LEISHMANIASIS AND DENGUE ARE DIFFICULT PROPOSITION

Pradeep Kumar Srivastava[1], Anju Viswan K[2]

[1]EX NVBDCP, Ghaziabad, India, [2]EX WHO, Jagdalpur, India

Lymphatic Filariasis (LF), Kala azar and Dengue are the public health concerns in India. These diseases are included in 20 identified NTDs. The surveillance of clinically manifested LF cases is done annually and updated once a year whereas, microfilaria prevalence is done in sentinel and random sites @ 1 site per million population as per WHO guidelines. Visceral leishmaniasis or Kala azar case search is also done in endemic areas for both with symptoms or for PKDL ones unlike malaria where surveillance is done routinely from all areas mostly at weekly or fortnightly intervals. Similarly, the surveillance of dengue cases is also institution (hospitals/labs) based. The integration of such type of surveillance would have various challenges like skill of the technicians for all the three diseases, different diagnostic labs and partial verticality in human resource etc. The various challenges including control command of human resource, difference in skill development and vertical implementation specific to surveillance, case detection and management in respect of these three NTDs namely LF, Kala azar and dengue prevalent in India need to be carefully looked into before considering integrated surveillance, however, vector surveillance can be undertaken in an integrated manner so that evidence generated can be used for action.

5604

IMPLEMENTATION OF A SUSTAINABLE AEDES AEGYPTI CONTROL STRATEGY: A COMMUNITY-BASED MODEL

Harold Suazo[1], Lester Lorente[2], Jacqueline Mojica[1], Jose Juarez[3], Jorge Ruiz[1], Laura Chanchien[2], Josefina Coloma[4]

[1]Sustainable Science Institute, Managua, Nicaragua, [2]Fundacion AMOS, Health and Hope, Managua, Nicaragua, [3]Sustainable Science Institute, Guatemala, Guatemala, [4]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Dengue, Chikungunya, and Zika viruses pose significant challenges for public health disease management in the tropics. The control of these arboviruses has traditionally relied on strategies focused on the mosquito vector, Aedes aegypti, through insecticides or more recently with the use of suppression or replacement strategies. Traditional efforts have failed to contain arbovirus transmission or control the vector, and while novel technologies have shown promising results they are still being tested. We implemented a sustainable community-focused Participatory Action Research methodology for Ae. aegypti control based on the Care Group and DengueChat programs that have been previously evaluated in high-risk communities for dengue in Managua, Nicaragua. Between 2017 and 2020, house-to-house visits were made to promote container management. These were carried out jointly between a community "brigadista" (volunteer) and a household participant. All containers with water inside and outside of the household were checked to promote resident-led elimination of breeding sites. Our team promoted the implementation without carrying out the removal of positive containers. Subsequently, the "brigadista" coordinated meetings with neighbors to build rapport based on the evidence of the control activities and generate collective achievements with neighbors to avoiding stigmatization. Throughout the study, the Ministry of Health carried out routine control measures in the area. In the baseline wet season of 2017, we found 161 pupae per household, 38 pupae per container, and 0.35 pupae per person. At the baseline of the dry season in 2018, we found 60 pupae per household, 20 pupae per container, and 0.13 pupae per person. After the implementation of our control strategy, we observed a Reduction of 81% for pupae per household, 64% pupae per container, and 81% pupae per person. With a sustained reduction of productive containers in the area. Our results show that the inclusion of communities in the management and control activities of Ae. aegypti can be maintained and run by community members and sustained over time.

5605

COST EFFECTIVENESS OF COMPARATIVE SURVEY DESIGNS FOR HELMINTH CONTROL PROGRAMS: POST-HOC COST ANALYSIS AND MODELLING OF THE KENYAN NATIONAL SCHOOL BASED DEWORMING PROGRAM

Mark Minnery[1], Collins Okoyo[2], Grace Morgan[1], Andrew Wang[1], Olatunji Johnson[3], Claudio Fronterre[3], Antonio Montresor[4], Suzy Campbell[1], Charles Mwandawiro[2], Peter Diggle[3]

[1]Evidence Action, Washington DC, DC, United States, [2]Kenyan Medical Research Institute, Nairobi, Kenya, [3]Centre for Health Informatics Statistics and Computing, Lancaster University, Lancaster, United Kingdom, [4]World Health Organisation, Geneva, Switzerland

Soil-transmitted helminths (STH) and schistosomiasis comprise the most wide-spread NTDs globally. Preventative chemotherapy is a cost-effective approach to controlling morbidity of both diseases, but relies on large scale surveys to determine and revise treatment frequency. Availability of detailed information on survey costs is limited despite recent methodological surveying innovations. We micro-costed a survey of STH and schistosomiasis in Kenya, and linked results to precision estimates of competing survey methods to compare cost-efficiency. Costs from a 2017 Kenyan parasitological survey were retrospectively analyzed and extrapolated to explore marginal changes when altering survey size, defined by the number of schools sampled and the number of samples taken per school. Subsequent costs were applied to simulated precision estimates of model-based geostatistical (MBG) and traditional survey designs. Cost-precision was calculated for a range of survey sizes per method. Four traditional survey design scenarios, based around WHO guidelines, were selected to act as reference cases for calculating incremental cost-effectiveness ratios (ICERs) for MBG design. MBG designed surveys showed improved cost-precision, particularly if optimizing number of schools against samples per school. MBG was found to be more cost-effective under 87 of 92 comparisons to reference cases. This comprised 14 situations where MBG was both cheaper and more precise, 42 which had cost saving with precision trade off (ICERs; $8,915-$344,932 per percentage precision lost); and 31 more precise with increased cost (ICERs; $426-$147,748 per percentage precision gained). The remaining 5 comparisons represented extremes of MBG simulated site selection, unlikely to be applied in practice.

5606

SEROSTATUS OF ANTI-RABIES TITER VACCINE LEVELS IN IMPOUNDED DOGS IN MUNTINLUPA CITY, PHILIPPINES, 2021

Jairue Pattaguan Cafe

Research Institute for Tropical Medicine, Muntinlupa, Philippines

Rabies is a zoonotic disease transmissible thru bite by an infected rabid animal. It is a vaccine preventable disease wherein a titer of 0.5 IU/ml is considered on protective level based on the WHO and WOAH (World Organization for Animal Health, formerly known as OIE). This study aims to investigate the serostatus of anti-rabies titer vaccine level that is impounded dogs in Muntinlupa city. Two hundred and fifty-two (252) serum samples were collected from dogs that is impounded in Muntinlupa city pound with unknown history of vaccination, out of these 86 (34.13%) dogs showed antibody titer above 0.5 EU/ml. all dogs collected with serum samples were processed and tested using ELISA with manufacturer's graphpad prism software to check all computation of the vaccinal immune response. Out of 252 serum samples, 166 (65.87%) impounded dogs showed anti-rabies antibody titer below 0.5 EU/ml/ indicating susceptibility to rabies infection and thereby posing possible threat to surrounding human and animal population in the area.

ASSESSING HEALTH SYSTEM'S PERFORMANCE FOR NEGLECTED TROPICAL DISEASES (NTDS) THROUGH WHO'S DATA QUALITY ASSESSMENT (DQA) TOOL IN FOUR WEST AFRICAN COUNTRIES

Kaustubh Wagh, Dillon Tindall, Diana Stukel

FHI360, WASHINGTON DC, DC, United States

The WHO's Data Quality Assessment (DQA)for Neglected Tropical Diseases (NTDs) is an important Monitoring and Evaluation (M&E) tool that can be used after Mass Drug Administration (MDA) to analyze data quality. The tool evaluates two parts: 1) Verification of MDA data, which includes verification factor (VF, ratio of recounted and reported numbers) for up to five indicators, and 2) An assessment of data management and reporting system through a. M&E structure, b. Indicator reporting guidelines, c. Data-collection, reporting tools, d. Data management processes, and e. Links with the national reporting system. Act to End NTDs | West is a five-year USAID-funded program that aims to eliminate or control five NTDs (LF, Trachoma, OV, SCH, and STH) in 11 West African countries. It routinely implements DQAs in its portfolio. We summarized data across seven DQAs (84 service delivery points) across four West African countries. The average verification factor was 94.4 (SD-20), demonstrating potential over-reporting for indicators assessed ("Number of pills administered" and "Number of people treated.") The scores were high for all five system assessments, particularly Indicator reporting guidelines (3.0 out of 3.0) and Links with national reporting system (2.9 out of 3.0). We explored the association between system scores and the VF to identify ways of enhancing data quality using DQAs. The VF and total system scores had a moderate positive correlation, r= 0.42. (pr<0.05). Additionally, we built a linear regression model with VF as the outcome variable and five system scores, border districts, and MDA

rounds as independent variables. The analysis showed positive associations between VF and M&E structure, data collection, and reporting tools, where VF increased by 0.10 (95% CI: 0.01, 0.20), and 0.45 (95% CI: 0.27, 0.63) respectively per unit increase in the system score. We observed that the number of MDA rounds and border districts had an inverse relationship with VF. These findings indicate that improving system scores (a & b) would enhance the accuracy of MDA data (VF). The programmatic response could also include focusing on improving MDA at border districts.

5608

MEASURING THE OUTCOME OF THE MASS DRUGS ADMINISTRATION OF LYMPHATIC FILARIASIS THROUGH SENTINEL AND SPOT SITES SURVEYS FROM 2012 - 2021

Abraham Wlah Nyenswah

Ministry of Health, Monrovia, Liberia

The results of the survey show that the disease is endemic in 13 of the 15 counties. The programme began implementing the first LF MDA, using a community distribution method, in 2012 in all 13 endemic counties. The programme has subsequently treated in 2013, 2015-2019 and 2021 in all endemic counties. Based on WHO guidelines to monitor the progress and impact of MDA, Sentinel sites must be identified in each implementation unit for evaluation after every 3 rounds of MDA. The program has conducted 3 destined Sentinel and Spot Check Sites Surveys in the Counties. The objective is to showcase the progress of MDA in reducing micro filarial in the communities through monitoring and Evaluation of Sentinel and Spot sites survey at the county level. To showcase results and data indicating a downward trend of the impact of MDA only lymphatic filariasis with the use of Albendazole in Liberia. To demonstrate the strategies in determining the impact of the Mass Drug Administration in controlling and eliminating Lymphatic Filariasis in Liberia. The Sentinel and Spot Check sites survey were conducted with a cross-sectional approach whereby people ages 5 years and above were sampled. Samples collected from participants were tested with Filarial Test Strips and counting chambers. The method of sample collection and testing were recommended by WHO. The NTD programme has conducted three sentinel site surveys; the first, baseline, was conducted in 2012 in 11 sites and the second was conducted in 2016 in 11 sites across the same 11 counties. The second survey was conducted in 4spot-check sites and 7 sentinel sites. The county of River Gee had an increase from 0% to 0.99%Mf. Maryland, the only county with a MF rate over 1% showed a reduction from 11.37% to 8.36%.The slow rate of reduction is likely attributed to receiving 2 rounds of MDA instead of 3 rounds.

5609

INCIDENCE OF SNAKEBITES IN RURAL POPULATIONS OF REPUBLIC OF CONGO

Lise B. Mavoungou[1], Kate Jackson[2], Joseph Goma-Tchimbakala[1]

[1]Institut national de Recherche en Sciences Exactes et Naturelles (IRSEN), Brazzaville, Congo, Republic of the, [2]Withman College, Walla Walla, WA, United States

Snakebites are a real social, economic and public health problem in the world. Few studies on snakebites have been conducted in Congo. The objective of this study is to report data on the risk and incidence of snakebites in rural populations in the Republic of Congo. A household survey of rural populations was conducted in 5 districts. This household survey was conducted using a questionnaire that took into account the characteristics of snakebite victims, the circumstances of the bite (location, season, time of day, activity) and the victim's recourse to treatment (traditional practitioners, dispensaries, self-medication). For the calculation of incidence, the average age of the respondents was used as a proxy for the period covered by the survey, thus completing the denominator. The collected data were entered into Microsoft Excel 2013, exported, and analyzed using Package for Social Science (SPSS) version 22 software. A total of 133 snakebite cases were recorded during the study period. In Okoyo District, 80 snakebite cases were reported and 2 deaths recorded. In Enyéllé District, 35 cases of snakebites were reported and 5 deaths were recorded. In Gamboma, 13 cases of snakebites were reported and no deaths were recorded. In the districts of Tchiamba-Nzassi and Mokéko, 1 case and 4 cases of snakebites were respectively recorded with no deaths. The incidence measured during this survey was 2857 bites per 100,000 inhabitants per year in Okoyo, 3535 bites per 100,000 inhabitants per year in Enyellé and 1032 bites per 100,000 inhabitants per year in Gamboma. More than half of the victims sought traditional care in Okoyo, Enyelle and Gamboma districts. While in Enyelle, 28.57% of cases used traditional-modern care and 7.69 of cases in Gamboma used modern care.This study highlights the need to intensify snakebite surveys throughout Congo by conducting surveys at three levels: health facilities, households and traditional healers in order to have a more general knowledge of snakebite victims. A program to raise awareness among rural populations about the dangers involved should be put in place.

5610

UTILITY OF THE LOOP-MEDIATED ISOTHERMAL AMPLIFICATION ASSAY FOR THE DIAGNOSIS OF VISCERAL LEISHMANIASIS FROM BLOOD SAMPLES IN ETHIOPIA

Dawit Gebreegziabiher Hagos[1], Yazezew Kebede kiros[1], Mahmud Abdulkadir[1], Dawit Wolday[1], D. F. Henk Schallig[2]

[1]Mekelle University, college of health Sciences, Mekelle, Ethiopia, [2]University of Amsterdam, Academic Medical Centre (AMC), Amsterdam, Netherlands

Rapid and accurate visceral leishmaniasis (VL) diagnosis is needed to initiate prompt treatment to reduce morbidity and mortality. Here, we evaluated the performance of loop-mediated isothermal amplification (LAMP) assay for the diagnosis of VL from blood in an endemic area in Ethiopia. LAMP was positive in 117/122 confirmed VL cases and negative in 149/152 controls, resulting in a sensitivity of 95.9% (95% CI: 90.69-98.66) and a specificity of 98.0% (95% CI: 94.34-99.59), respectively. The sensitivity of the LAMP assay was 95.0% (95% CI: 88.61-98.34) in HIV-negatives and 100% (95% CI: 85.18-100.0) in HIV-positives. Compared with microscopy, LAMP detected 82/87 (94.3%, 95% CI: 87.10-98.11) of the microscopy1 cases and was negative in 11/27 (40.7%, 95% CI: 22.39-61.20) of the microscopy2 cases. Compared with the rK39 serology, LAMP detected 113/120 (94.2%, 95% CI: 88.35-97.62) of the rK391 cases and was negative in 149/154 (96.8%, 95% CI: 92.59-98.94) of the rK392 cases. However, when compared with microscopy only, rK39 detected 83/87 (95.4%, 95% CI: 88.64-98.73) of the microscopy1 cases and negative in only 12/27 (44.4%, 95% CI: 25.48-64.67) of the microscopy- cases. There was an excellent agreement between rK39 and LAMP (Kappa 5 0.91, 95% CI: 0.86-0.96). Furthermore, an algorithm using rK39 followed by LAMP would yield a sensitivity of 99.2% (95%CI: 95.52-99.89) and a specificity of 98.0% (95% CI: 94.34-99.59). The findings demonstrate that LAMP assay is an accurate and rapid molecular assay for VL diagnosis, including in HIV-1 co-infected patients, in an endemic setting.

5611

VISCERAL LEISHMANIASIS: IMPROVED MOLECULAR DIAGNOSIS USING THE MINI DIRECT ON BLOOD PCR NUCLEIC ACID LATERAL FLOW IMMUNOASSAY (DBPCR-NALFIA)

Henk Schallig[1], Norbert Van Dijk[1], Daniela Huggins[1], Eugenia Carrillo Gallego[2], Dawit Hagos[1], Sandra Menting[1]

[1]Academic Medical Centre, Amsterdam, Netherlands, [2]Instituto de Salud Carlos III, Madrid, Spain

Accurate and early diagnosis of Visceral Leishmaniasis (VL) is important to install proper treatment, because of the fatality of the condition and the high toxicity of available treatments. Current diagnostic methods include parasitology and serology (with rK39 dipstick test and direct agglutination test). These methods do have limitations (patient safety or diagnostic accuracy), and molecular testing is proposed to improve diagnosis. Current molecular tools, in particular PCR, have high accuracy for detecting VL, however their complexity and high costs make their use

unsuitable for endemic areas with limited resources. Consequently, there is a need for a simple molecular diagnostic test that can be implemented in resource limited setting. We have developed a miniaturized direct-on-blood PCR nucleic acid lateral flow immunoassay (mini-dbPCR-NALFIA) as an innovative, easy-to-use molecular assay for the diagnosis of VL in these particular settings. Unlike other simplified molecular methods, such as LAMP, the mini-dbPCR-NALFIA does not require DNA extraction and utilizes a handheld, portable thermal cycler powered by a solar-charged power pack enabling to perform the test without any laboratory infrastructure. Reading of results is done using a rapid lateral flow strip. In the present study we have conducted a laboratory evaluation on the mini db-PCR-NALFIA to determine its diagnostic accuracy. Patient samples (N=146) with suspected VL were tested using the mini db-PCR-NALFIA and compared to conventional PCR (reference test). Sensitivity and specificity represented the accuracy. Cohen's k determined the degree or agreeableness between the mini db-PCR-NALFIA and other diagnostic tests (PCR and rk39 rapid test). Compared to qPCR, the mini db-PCR-NALFIA for VL had a sensitivity of 95.83% (95% CI, 88.30%-99.13%) and a specificity of 97.22% (95% CI, 90.32% - 99.66%). The agreement between both tests was excellent (k-value: 0.93). The Limit of Detection of the platform is around 10 parasites per microliter of blood (spiked with promastigotes).

5612

COST EFFECTIVENESS ANALYSIS OF CONGENITAL CHAGAS DISEASE SCREENING METHODS IN BOLIVIA

Steffany Vucetich Valdivia

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Of the 6 to 7 million global cases of Chagas disease, Bolivia is the country with the highest prevalence, many due to congenital transmission, which is one of the routes of transmission of Chagas disease. The WHO calls for the elimination of congenital Chagas disease by 2030. This study compares the cost-effectiveness of three methods for a national screening intervention: qPCR, Western Blot, and microhematocrit (all utilized at ages zero, one, and nine months). We used decision tree analysis to compare the cost effectiveness of three screening methods: i) microhematocrit, ii) qPCR, and iii) Western blot, considering microhematocrit as the standard of care. Transition probabilities were taken from previous studies or derived as assumptions. Previous studies and primary data collection from Bolivia provided cost data. We performed one-way sensitivity analysis to test the model's uncertainty, represented through a tornado diagram. Parameters included were the methods' respective sensitivities; the probability of being tested at zero, one, and nine months; and the costs of the microhematocrit, qPCR, and Western Blot tests. The model indicates that screening intervention using qPCR is more cost-effective than using microhematocrit, considering a willingness to pay (WTP) threshold of three times the GDP per capita of Bolivia. National implementation of qPCR would result in earlier diagnosis of congenital Chagas disease, resulting in effective treatment for infants and prevention of future costs. We continue to develop our model, comparing Western Blot data with that of qPCR and microhematocrit. We also continue to analyze the effectiveness of these interventions, using DALYs to consider long-term effects. The most common method to diagnose congenital Chagas disease in Bolivia, microhematocrit, has low sensitivity: more than 40% of infected infants are misdiagnosed due to false negatives. qPCR's high cost and Western Blot's long learning curve have resulted in less frequent use. Considering the direct and indirect costs for Chagas disease patients, the two methods' overall cost-effectiveness must be re-evaluated.

5613

POTENTIAL BIOMARKERS FOR ASYMPTOMATIC VISCERAL LEISHMANIASIS AMONG DEPLOYED U.S. MILITARY PERSONNEL

Fernanda Fortes de Araujo[1], Ines Lakhal-Naouar[2], Rupal Mody[3], John Curtin[4], Edgie-Mark Co[5], Nathanial K. Copeland[6], Nancy Koles[1], Hui Liu[1], Anna Wooten[1], Naomi Aronson[1]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Walter Reed Army Institute of Research, Bethesda, MD, United States, [3]William Beaumont Army Medical Center, El Paso, TX, United States, [4]Walter Reed National Military Medical Center, Bethesda, MD, United States, [5]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [6]Tripler Army Medical Center, Honolulu, HI, United States

Visceral leishmaniasis (VL) is caused by infection with Leishmania (L.) donovani or L. infantum (syn. L. chagasi) parasites. Despite infection, most individuals immunologically control the parasite and remain asymptomatic. However, some people progress to symptomatic VL, potentially leading to death if untreated. Although several immune biomarkers of symptomatic VL have been described; our objective was to determine new biomarkers capable of identifying asymptomatic visceral leishmaniasis (AVL), in addition to interferon gamma. Levels of chemokines/cytokines in supernatants of peripheral mononuclear blood cells (PBMC) from 35 AVL+ healthy Iraq-deployed participants, stimulated in vitro with soluble Leishmania antigen (SLA) for 72 hours, were assessed by a bead-based assay that allows the measure of multiple analytes. Additionally, we evaluated the chemokine/cytokine levels in supernatants from whole blood of 18 subsequently-immunosuppressed AVL+ Iraq and Afghanistan deployers (tumor necrosis factor α inhibitor users, n=7; renal transplant, n=4; or HIV infection, n=7), stimulated in vitro with SLA for 24 hours and tested by the same assay. We also studied blood of AVL negative controls, both healthy (n=14) and immunosuppressed (n=22). Three biomarkers: monokine induced by gamma interferon (MIG) (AUC 0.87, 71% sensitivity), monocyte chemoattractant protein-1 (MCP-1) (AUC 0.79, 91% sensitivity) and interleukin (IL)-8 (AUC 0.80, 66% sensitivity) were detected at high levels in AVL+ supernatants from stimulated cultures from healthy deployers compared to uninfected controls. MCP-1 was detected at high levels in AVL+ persons living with HIV (AUC 0.92, 100% sensitivity). In conclusion, chemokine profiling is a useful strategy for identifying cellular immune responses in AVL+ individuals. Our results show that MCP-1 is a candidate biomarker in assessing AVL in stimulated whole blood of persons living with HIV and in PBMC of healthy adults and MIG (and IL-8 to a lesser extent) is also possible biomarkers in assessing AVL+ in healthy deployers.

5614

OPTIMIZATION AND VALIDATION OF RECOMBINANT ANTIGEN BASED INDIRECT ELISA FOR CUTANEOUS LEISHMANIASIS

Charani Karunathilake, Narmadha Alles, Sachee Bhanu Piyasiri, Isurika Weerasinghe, Nipuni Chandrasiri, Rajika Dewasurendra, Nadira Karunaweera

Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Cutaneous leishmaniasis (CL) in Sri Lanka is caused by Leishmania donovani, a parasite having a potential for visceralization. Even though CL is not generally considered as a disease that induces humoral responses, several recent studies have reported antibody responses against CL. This study was designed to assess the antibody responses of CL patients in Sri Lanka by optimizing and validating a recombinant rK39 and KMP11 antigen-based ELISA. Optimization of the ELISA included the checkerboard titration method to determine the optimum antigen concentration and sample dilution. The ELISA was conducted using a standard protocol after optimization. The optimum antigen concentration of rK39 ELISA was 3.0 µg/ml and the optimum sample dilution was 1:400. The optimum antigen concentration for KMP11 ELISA was 2.0 µg/ml and the optimum sample dilution was 1:50. The optimized ELISAs were conducted for 140 serum

samples from confirmed CL patients (both treated and non-treated) and for negative samples taken from healthy individuals from non-endemic areas. The established ELISA protocol using parasite crude antigen was also performed for comparison. The results were analyzed using SPSS V26.0 software and cut-off values for each antigen were determined by Receiver-Operator-Characteristic (ROC) curve. ELISA for rK39 showed 51.4% sensitivity and 60% specificity. ELISA for KMP11 showed 71.4% sensitivity and 52% specificity. ELISA for parasite crude antigen showed 84.3% sensitivity and 85.7% specificity. Therefore, the parasite crude antigen ELISA was a better assay than recombinant antigen based ELISAs for the detection of ani-leishmania antibodies. The low sensitivity and specificity of the tests are the major limitation when developing these into a reliable diagnostic tool for CL.

5615

EVALUATION OF NOVODIAG® STOOL PARASITES TEST, A HIGH-PLEX STOOL TEST, AGAINST TRADITIONAL METHODS IN A HIGH-RISK TRAVELLER AND MIGRANT POPULATION AS A POTENTIAL FOR QUICKER AND MORE ACCURATE IDENTIFICATION OF INTESTINAL PARASITES

Rohma Ghani[1], Spencer Polley[2], Rashmita Bodhani[2], Amina Moussa[2], Peter L. Chiodini[1], Gauri Godbole[1], Laura Nabarro[1]

[1]University College London, London, United Kingdom, [2]Health Services Laboratories LLP Analytics, London, United Kingdom

Introduction. Identification of intestinal pathogens via stool microscopy requires highly trained personnel, multiple samples and is labour intensive. Early identification is key to limiting spread and informing treatment to prevent clinical complications. We aimed to compare traditional methods with the Novodiag® Stool Parasites test (Mobidiag, Espoo, Finland), a CE-marked high-plex test that combines real-time PCR (rt-PCR) and microarray assays for the identification of 25 pathogens. Methods. Stool samples from traveller and migrant populations were run on the Novodiag® Stool Parasites test (NSP) and a Giardia intestinalis in-house rt-PCR assay. Positive samples were analysed using traditional microscopy staining of formalin-ethyl acetate faecal concentrates for ova, cysts and parasites (OCP). Results. Between September 2022 and February 2023, 454 tests for 448 patients were run on the NSP. One assay failed due to sample inhibition. 48 patients had positive results; 4 patients had dual infection (3 on NSP and 1 on OCP). Stool OCP was performed on 46 samples, results were concordant in 25 out of 46 samples. Hymenolepis nana was identified in two OCP samples which were not identified by NSP and on two NSP samples not seen on OCP. NSP detected more Enterobius vermicularis, Schistosoma spp, Strongyloides stercoralis, Ancylostoma duodenale, Enterocytozoon bieneusi, Necator americanus and Taenia spp than OCP. Detection of Giardia was similar between standard rt-PCR and NSP; there were 19 positive Giardia samples in NSP, 17 of which were also detected by rt-PCR. One sample was detected by rt-PCR and not detected by NSP. Discussion. NSP had a greater detection rate for a wider range of pathogens than OCP and is equivalent to rt-PCR for detection of Giardia. However, as it cannot identify all intestinal parasites, it cannot replace standard microscopy, but can provide an appropriate additional diagnostic tool for identification of common pathogens with a more rapid turn-around time, greater number of pathogens identified and requires less skilled personnel.

A SEROLOGICAL 'TEST OF TREATMENT RESPONSE' FOR CHAGAS DISEASE

Sarah Miller[1], Vashti Irani[1], Ester Sabino[2], Michael P. Busch[3], Ursula Saade[4], Maan Zrein[4], Alicia Majeau[1], **Andrew Levin**[1]

[1]Kephera Diagnostics, LLC, Framingham, MA, United States, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Vitalant Research Institute, San Francisco, CA, United States, [4]INFYNITY Biomarkers, Lyon, France

Chagas disease, caused by the protozoan Trypanosoma cruzi, is the most prevalent parasitic disease in the western hemisphere. Treatment with available antiparasitics is lengthy, often with adverse events, and efficacy varies depending on age and stage of disease. Determining if treatment is effective is critical, as ~30% of infected individuals will develop cardiac or gastrointestinal complications that can be fatal. There is currently no standardized assay to measure treatment response and guide clinical decision-making. Accordingly, we sought to develop a 'Test of Treatment Response' (TTR) to measure post-treatment serological decline as an accepted surrogate for decreasing parasite burden. To identify potential biomarkers, we probed a peptide array comprising ~8000 sequences from 41 known T. cruzi antigens with IgG from Chagasic subjects and healthy controls. Four peptides were selected based on sensitivity against a geographically diverse panel of Chagasic sera and on responsiveness to serological decline in post-Rx samples. A prototype ELISA using the 4 peptides was tested on a longitudinal treatment cohort from São Paulo, Brazil that included samples pre-Rx and 6,12, and 36-months post-Rx. When tested on samples collected 12m post-Rx, each peptide biomarker detected serological decline (defined as ≥20% decline in IgG titer) in a larger proportion of individuals (45-71%) than conventional ELISA (22%). Using a simple algorithm to combine individual peptide results, the peptide ELISA detected serodecline in 72/76 patients at 36m post-Rx compared to 16/76 by conventional ELISA. Our results demonstrate that synthetic peptides may be more sensitive serologic indicators of treatment response than full-length recombinant or native proteins, revealing serodecline faster and to a greater magnitude than conventional ELISA. However, further studies are needed to determine the exact relationship between serodecline and parasite burden. Development and clinical evaluations of the peptide TTR assay are ongoing with the ultimate aim to provide commercial ELISA and point-of-care versions.

EVALUATION OF TOXOPLASMA GONDII EXCRETORY/SECRETORY AND MEMBRANE ANTIGEN FOR THE DETECTION OF INFECTION IN ACUTE PHASE BY WESTERN BLOTTING

José L. Pasco Espinoza[1], Juan A. Jimenez Chunga[2], Edith S. Málaga[1], Solange B. Custodio Custodio[1], Manuela R. Verastegui Pimentel[1], Martiza Calderón Sánchez[1], Cesar M. Gavidia Chucan[3], Robert H. Gilman[4]

[1]Infectious Diseases Laboratory Research-LID, Faculty of Science and Philosophy, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Biological Sciences, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]The Department of International Health, Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Baltimore, MD, United States

One of the most common zoonoses affecting humans is toxoplasmosis, which is caused by Toxoplasma gondii and represents a danger because of the significant morbidity and mortality levels in at-risk populations: immunosuppressed patients and pregnant women. Since at-risk populations need to be constantly monitored, a confirmatory test that is sensitive and specific enough to detect and differentiate the different stages of the disease is needed. To meet this objective, 25 Holtzman rats of 30 days old were infected intraperitoneally with 105 T. gondii tachyzoites of the RH strain and followed up to 90 days post infection. Blood was collected and used for disease detection using immunological tests to detect proteins and antibodies generated during infection (acute and chronic phase). The antigens used were total antigen lysate (TLA), excretory secretory antigens (E/S) and membrane antigens. Western blot results showed that using the excretory secretory (E/S) antigens, 25 kD and 30 kD bands were recognised that only appeared in the rats of the 30 and 60 day post infection (chronic phase) group. When the antigens of the membrane fraction were confronted against the sera of rats from the 60 days post infection group (chronic phase), the most significant bands detected were 80 kD, 19 kD, 15 kD, as these bands were not evident in the cytoplasmic fraction when confronted with the same sera. The T. gondii total antigen lysate (TLA) showed too many bands when confronted with rat sera from the chronic and acute group, and it was not possible to establish significant

differences between the two phases. This study concludes that excretory secretory antigens (E/S) and membrane antigens are the most optimal to differentiate the chronic and acute phases of infection because the bands can be observed better separated and with higher specificity (30 and 60 kDa in the E/S antigen) compared to TLA, where too many and in many cases non-specific bands are reported, making the diagnosis of the phase more difficult. These results will serve as a basis for studies in at-risk human populations to differentiate between chronic and acute phases of infection.

DRIED BLOOD SPOTS: A SUITABLE ALTERNATIVE TO USING WHOLE BLOOD SAMPLES FOR DIAGNOSTIC TESTING OF VISCERAL LEISHMANIASIS IN THE POST-ELIMINATION ERA

Prakash Ghosh, Dinesh Mondal
icddr,b, Dhaka, Bangladesh

Serum or whole blood collection, processing, transport and storage still represent a significant challenge in low resource settings where mass surveillance is required to sustain disease elimination. Therefore, in this study, we explored the diagnostic efficacy of dried blood spots (DBS) as a minimally invasive and potentially cost-effective alternative sampling technique to whole blood sampling procedures for subsequent detection of Leishmania donovani antibodies or DNA. Archived serum, DNA samples from whole blood of visceral leishmaniasis (VL) cases and healthy controls, and DBS from corresponding cases and controls, were used. Both molecular and serological assays were optimized to detect L. donovani antibodies or DNA in DBS elute and results were compared against those obtained with whole blood. Serological assays (both rK28 ELISA and rK39 ELISA) of DBS samples showed sensitivity and specificity of 100% and had excellent agreement with results from whole blood samples (kappa value ranged from 0.98-1). Bland-Altman analysis of OD values from rK28-ELISA with DBS elute and patients' serum showed an excellent agreement (ICC=0.9) whereas a good agreement (ICC=0.8) was observed in the case of rK39-ELISA. However, qPCR and RPA of DBS samples had a diminished sensitivity of 76% and 68 %, respectively, and poor agreement was observed with the whole blood samples.Our results demonstrate that DBS offer excellent diagnostic efficiency for serological assays and represent a viable alternative to whole blood sampling procedures.

5619

ACCURACY OF THE "TESA-BLOT RAPID TEST" FOR THE DIAGNOSIS OF CHAGAS DISEASE

Edith S. Malaga[1], Manuela R. Verastegui Pimentel[1], Shirley Equila[2], Jean C. Belarde Leigue[2], Clarisa R. Chavez[2], Freddy Tinajeros[2], Robert H. Gilman[3]
[1]Cayetano Heredia Peruvian University, Lima, Peru, [2]Prisma Charitable Association, Lima, Peru, [3]Department of International Health, Johns Hopkins University, Baltimore, MD, United States

A common form of Trypanosoma cruzi transmission is vertical mother-to-child transmission, which is the main form of transmission in nonedemic countries in addition to being a significant -but neglected-contributor in endemic regions. Lack of awareness and timely diagnosis in rural endemic areas, exacerbate high infection rates, with more than one million Latin American women of childbearing age are infected with Chagas disease. Only approximately 10% of these women are aware of their infection leaving thousands of newborns at risk of being born infected. The lack of access to rapid and accurate diagnostic assays makes it difficult to detect positive mothers, especially since many of these women have limited contact with healthcare workers prenatally and only come to the hospital for delivery and then return to a rural area. Conventional diagnostic tests- such as HAI, IFA, and ELISA-. lack reproducibility and reliability of results and take hours to process. Therefore, the test results are often not available until after the mother has left the health centre. In order to address this issue, we developed a rapid Western blot (using the trypomastigote excretory-secretory antigen), which has a sensitivity of 100% and a specificity of over 94%. For the evaluation of the standardized "TESA Blot rapid test", 35 samples from mothers and samples from their babies (34 samples) were tested, comparing the standard TESA to the new reapid TESA. In conclusion, it was possible to detect patients in the acute phase in 25 minutes and the chronic phase in 35 minutes, compared to the 14 hours needed for the original TESA blot. This allows for timely follow-up and treatment for the mother and newborns.

5620

EVALUATION OF TRYPANOSOMA CRUZI AMASTIGOTE ANTIGENS IN CARDIAC TISSUE AT DIFFERENT POST-INFECTION TIMES

José O. Zapata More[1], Edith S. Malaga Machaca[1], Manuela R. Verastegui Pimentel[1], Robert H. Gilman[2]
[1]Cayetano Heredia Peruvian University, Lima, Peru, [2]The Department of International Health, Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Lima, Peru

Chagas disease is caused by Trypanosoma cruzi and affects between 6-7 million people mainly in Latin America. Many people in the acute phase have no symptoms and in some cases only general symptoms are present, which makes diagnosis difficult. It is known that 30% of infected persons develop cardiac manifestations after 20-30 years of infection. The development of chronic cardiomyopathy in infected persons increases the risk of death by 20% compared to other types of cardiomyopathy. Currently, government programs are not efficient in monitoring and diagnosing the disease. Therefore, it is important to develop better tools in in vivo models to understand the development of the pathogenesis of the disease. It is difficult to identify the presence of amastigotes when tissue parasitism begins to decline. The availability of specific polyclonal antibodies, conjugated with fluorophores or HRP, against amastigote would be a good alternative to identify them in a more efficient way. Therefore, axenic amastigotes, free of cells and other stages, were obtained by amastigogenesis from trypomastigotes of strain Y, cultured in LL-CMK2 cells and RPMI medium at 2% SFB. Trypomastigotes were incubated in medio Dulbecco's Modified Eagle's medium alto en glucosa (hgDMEM) with 20 mM MES buffer at pH 5 with 0.4% BSA (condition I) and without BSA (condition II). The evaluation of the transformation kinetics was performed by counting in Neubauer hemocytometer where it was observed that at 4 h of incubation 75% and 95% of the incubated parasites were transformed to amastigotes, in condition I and II, respectively. While at 8 h of incubation 97% and 100% were observed for condition I and II respectively, however with condition I at 12 h, 100% transformation was also observed. According to these results, successful amastigogenesis was obtained in both conditions, with faster transformation in condition II. These results contribute to the production of polyclonal antibodies from immunizing rabbits with the lysate of these amastigotes. In order to identify more specifically, by immunofluorescence or immunohistochemistry, the presence of tissue amastigotes in animals.

COMPARATIVE ANALYSIS OF A CHAGAS DISEASE RAPID DIAGNOSTIC TEST (RDT) FOR THE DETECTION OF ANTI-TRYPANOSOMA CRUZI ANTIBODIES AMONG SERUM COLLECTED FROM MULTIPLE REGIONS OF COLOMBIA

Norman L. Beatty[1], Omar Cantillo-Barazza[2], Paola Vásquez Escobar[2], Daniela Sánchez Aristizabal[2], Omar Triana-Chávez[2]
[1]University of Florida College of Medicine, Department of Medicine, Division of Infectious Diseases and Global Medicine, Gainesville, FL, United States, [2]Grupo Biología y Control Enfermedades Infecciosas, Universidad de Antioquia, Medellin, Colombia

Chagas disease (CD) is known to effect those living in impoverished and vulnerable circumstances, placing those at risk for vector-borne and oral transmission of Trypanosoma cruzi within endemic regions. Rapid Diagnostic Tests (RDT) for CD can be utilized in the field, local clinics and health facilities with limited access to a laboratory which requires specialized equipment and trained technicians. Serum collected and stored (-80C°) from individuals living within the CD endemic regions of

Sierra Nevada de Santa Marta (SNSM), Urabá, Boyacá, and Chocó, regions of Colombia from 2003 until present day, were tested with a lateral flow immunochromatographic assay (DPP® Chagas System; Chembio Diagnostic Systems, Inc.) and compared with confirmed positive and negative stored samples. Among these serum samples, CD was confirmed positive (n=102) with positivity to both T. cruzi IgG ELISA and Immunofluorsecence Antibody (IFA) assays developed at the Universidad de Antioquia (UdeA) in MedellÍn, Colombia, from a T. cruzi isolate cultured from SNSM region of Colombia. Sensitivity and specificity of the UdeA T. cruzi IgG ELISA and IFAT among Colombian serum samples is 98% and 97%, respectively. DPP® Chagas System RDT utilizes a Micro Reader to interpret the immunochromatographic results with either, non-reactive, indeterminate, or reactive. Following manufacturer's protocol, 5µl of serum from both positive and negative serum samples were tested with DPP® Chagas System and results were available within 15 minutes. Results of testing reveal sensitivity of 98.88% [95% CI 93.96-99.97% (n=89/90)] were true negative and specificity of 97.05% [95% CI 91.65-99.39% (n=99/102)] were true positive. Failure rate of testing was 1.04% (n=2/192) in which testing had to be repeated due to non-functioning cartridge or invalid result. The DPP® Chagas System RDT was easy to use and provided both highly sensitive and specific results among those living with CD from these regions of Colombia. The use of RDTs for CD screening and diagnostics can help reach populations with limited resources in Colombia and other endemic regions.

5622

DETECTION OF A TOXOPLASMA GONDII ANTIGENIC PROTEIN AND ITS POTENTIAL USE IN THE NONINVASIVE DIAGNOSIS OF TOXOPLASMOSIS

Andrea Jackeline Diestra

Universidad Cayetano Heredia, Lima, Peru

Toxoplasma gondii is an intracellular parasite that can infect all warm-blooded living beings, including man. In immunocompetent patients the process is asymptomatic, however cysts persist for life in tissues, when the individual is immunosuppressed (transplants, pregnancy, HIV) reactivation of the active stage of T.gondii can become fatal. Non-invasive and confirmatory techniques are needed in order to detect active T.gondii infection in immunosuppressed individuals. A total of 20 urine samples from HIV patients separated into 2 groups were used: Group I: 10 HIV patients with suspicion of active toxoplasmosis with Cq values (35-20) in CSF samples in the amplification of a REP529 fragment, IgG positive and with a clinical diagnosis of Toxoplasmosis, Group II: 10 HIV patients negative for T.gondii. Hydrogel nanoparticles will be used in order to concentrate small proteins ≤30kD in urine, followed by dot blot detection of a dense granule protein (GRA1) of T.gondii. In GRA1 positive patients, a black spot was observed on the PDVF membrane, detecting GRA1 in 40% (4/10) patients in Group I, and in 0% (0/10) of patients in Group II. The use of nanoparticles in urine samples allowed the detection of GRA1, a dense granule protein of Toxoplasma gondii involved in the development of an active stage or reactivation stage due to immunosuppression, making this technique a promising tool for the non-invasive diagnosis of toxoplasmosis.

5623

ASSESSING THE TSETSE FLY MICROBIOME COMPOSITION AND THE POTENTIAL ASSOCIATION OF SOME BACTERIA TAXA WITH TRYPANOSOME ESTABLISHMENT

Bouaka Tsakeng Calmes Ursain

Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon

Tsetse flies are biological vectors of trypanosomes which cause African trypanosomiasis. No vaccine is available, and drugs are toxic with increasing emergence of resistance. Reducing vector competence can be additive tools to stop disease transmission. Some bacteria have been shown to be used as paratransgenic organisms capable of blocking trypanosome's development in flies. Understanding the role of tsetse microbiome in disease transmission could improve knowledge in initiatives to develop new vector control strategies. We aim to determine the microbiome composition of tsetse flies and their association with trypanosome establishment. Tsetse flies were collected from Campo, southern Cameroon and total DNA was extracted from fly bodies and heads separately. Trypanosome species were identified by PCR. Amplification of the V3-V4 region of the 16S rRNA gene followed by sequencing on Illumina miseq with subsequent metagenomic analyses were performed to identify the different bacteria communities. PCR analysis of 2186 Glossina p. palpalis revealed 20.08% trypanosome infections with Trypanosoma congolense (13.73 %,) the predominant species; 0.17 % were T. b. gambiense. 21.27% of infected flies produced mature infections. From 192 samples randomly sequenced, a total of 31 bacteria genera were identified with the primary symbiont Wigglesworthia displaying 47.29% abundance. Globally, significant differences were observed in the microbiome diversity among tsetse species, between teneral and non-teneral flies and between flies displaying or not displaying mature trypanosome infections. In addition, differential abundance testing showed several bacteria taxa such as Dechloromonas, Ralstonia and Serratia associated with trypanosome maturation in tsetse flies.This study has shown some bacteria associated with trypanosome infection maturation in flies, which therefore need further studies to investigate an understanding of their mechanism of action and alternatively, transformed and used to block trypanosome development in tsetse flies.

5624

SIMILARITIES BETWEEN GENES FOR TRYPANOSOMA CRUZI MICROTUBULE ASSOCIATED PROTEINS AND HUMAN INTERFERONS

Martin A. Winkler[1], Alfred A. Pan[2]

[1]Biotech Advisor, Lawrence, KS, United States, [2]TNTC, Inc., Pleasant Hill, CA, United States

Trypanosoma cruzi Microtubule Associated Proteins (MAPS) are encoded by a family of homologous genes. We have previously shown that one of these genes, coding for the T. cruzi human serodiagnostic antigen Ag36, is similar in gene sequence to human immune Tripartite Motif (TRIM) proteins, such as TRIM21. Since TRIM proteins are intrinsic to human innate immunity, we examined several cytokines key to innate immunity; for example, human Interferon and Interleukin genes. The Needleman-Wunsch Algorithm, which measures and scores the extent of similarity of two gene sequences, was used to compare Genbank M21331 (the Ag 36 gene) with these two genes, respectively. The tools and gene sequence analysis were performed and the results stored at https://usegalaxy.eu. Human Interferon gamma showed 17.9% identity, Human Interferon alpha displayed 13.6% identity, and Human beta Interferon indicated a 12.6% identity to M21331. Human Interleukin genes showed no significant similarity to M21331. The possible implications during T. cruzi infection and manifestation of Chagas' disease of these similarities to human Interferon genes and the 33 T. cruzi MAP genes will be discussed.

5625

HYBRID ASSEMBLY OF THE LEISHMANIA (VIANNIA) PERUVIANA GENOME

Fredy E. Villena[1], Maxy De los Santos B. De los Santos[2], Carmen Lucas[2], Danielle Pannebaker[2], Hugo O. Valdivia[2]

[1]Vysnova, Lima, Peru, [2]U.S. Naval Medical Research Unit No. 6. Department of Parasitology, Lima, Peru

Leishmania (Viannia) braziliensis complex encompasses two closely related species (L. (V.) braziliensis and L. (V.) peruviana) with different geographical distributions and disease phenotypes. Unlike L. (V.) braziliensis which has been extensively studied, L. (V.) peruviana is still largely uninvestigated. Furthermore, this latter species lacks a reliable or complete reference genome which is key for population genetics, functional studies, and surveillance. In this study we report a high-quality genomic sequence of L. (V.) peruviana obtained from combining long and short reads generated by high-throughput sequencing. For this purpose, genomic DNA from the MHOM/PE/87/PAB2880 L. (V.) peruviana strain was sequenced on

MinION nanopore and Illumina NovaSeq. The resulting Nanopore reads were used for de novo assembly using Flye 2.9.1 to generate contigs and chromosome scaffolds. Then Illumina reads were aligned onto these scaffolds with Minimap 2 2.17 to perform error correction, close gaps, reduce sequencing errors, and generate a consensus sequence. Nanopore sequencing resulted in 84.33Mb estimated bases contained in 19.24K unpaired reads (Length N50=10.89K) whereas Illumina sequencing resulted in 3.56Gb paired reads contained in 23.5M reads (Length N50=151bp). A BLAST search against the NCBI database showed that all reads aligned with at least one species of the Leishmania (Viannia) braziliensis complex. The kinetoplast genome (kDNA) was contained in a single 23.1Kb scaffold whereas the nuclear genome was contained in 197 scaffolds with a total length of ~35Mb (N50=36Kb). This version of the genome constitutes an improved assembly compared to the one previously reported for this species which was limited to 25Mb fragments into 27,873 scaffolds (N50=1.3Kb). Referenced-based, de novo gene annotation and a deeper analysis of chromosome structure, copy number, and single nucleotide polymorphisms are currently being conducted on this improved assembly. Our results will provide a foundational backbone for comparative genomics, phylogenetics, and surveillance of Leishmania (Viannia) peruviana.

5626

MECHANISM OF INTESTINAL BARRIER REPAIR IN GIARDIASIS

Rita Taye Kosile, Vanessa Angelova, Evan Pannkuk, Steven Singer

Georgetown University, Washington, DC, United States

The protozoan parasite Giardia duodenalis is the cause of the common diarrheal disease, giardiasis. Diarrhea is one of the most severe acute symptoms, however, infections can be subclinical. It is transmitted via ingesting infectious cysts in contaminated water or food. Giardiasis is one of the main causes of growth stunting in children under the age of two in developing countries. It has been demonstrated that alterations in intestinal barrier integrity contribute to reduced nutrient absorption, which leads to growth stunting in children. Although intestinal barrier abnormalities have been associated with infection, nothing is known about how the intestinal barrier repairs itself after an infection. Previous studies have demonstrated that Giardia infection is associated with intestinal dysbiosis in humans and animals. We are investigating the function of aryl hydrocarbon receptor (AHR) in barrier repair after a Giardia infection because AHR signaling has been demonstrated to promote intestinal repair in other systems. We measured the levels of particular AHR ligands originating from the microbiome in the plasma of infected C57BL/6 mice and saw a decrease in indole-3-ethanol and indole-3-pyruvic acid after 21 days of infection. As IL-22 signaling can also enhance barrier repair, we quantified IL-22 transcripts by RT-PCR and found significantly elevated levels of IL-22 mRNA in infected animals. Our findings suggest that Giardia can inhibit barrier repair by altering the microbiome's ability to produce AHR ligands, but that in some situations, IL-22 can reverse this defect. This study will give better insight into developing effective dietary interventions to prevent growth stunting in infected children.

GENOMIC ANALYSIS DEMONSTRATES EXTENSIVE DIVERSITY AND SUBTLE POPULATION STRUCTURE IN PLASMODIUM VIVAX ACROSS 9 DISTRICTS OF ETHIOPIA

Alebachew Kebede

University of Monash, Melbourne, Australia

Ethiopia suffers the greatest burden of Plasmodium vivax in the African continent with infections contributing as much as 40% of malaria morbidity. Efforts to contain and eliminate P. vivax are constrained by limited knowledge of the major adaptations and epidemiological drivers sustaining local endemicity. We conducted genomic analysis of 155 P. vivax genomes across 9 districts in Ethiopia. The genomic data was generated within the MalariaGEN P. vivax Community Project, using isolates sourced from cross-sectional surveys conducted in Ethiopia from 2012-2016. Measures of within-host and population diversity and structure were conducted using scikit-allel, ADMIXTURE, hmmIBD and custom scripts. Signatures of selection were detected using REHH software with cross-country comparisons against MalariaGEN data from sites in Thailand (n=129) and Indonesia (n=191) with respective low and high levels of chloroquine resistant P. vivax. A high proportion of Ethiopian infections were polyclonal (26%), with 44.7 % comprising clones with high relatedness (identity-by-descent >25%), indicating frequent co-transmission and superinfection. Several infection networks comprised isolates from neighbouring as well as more distal districts, indicating complex patterns of infection spread between communities. Amplification of the Duffy binding protein gene (pvdbp1) was observed at high frequency in 8 districts (range 16%-75%), with up to 5 copies, suggestive of an important local adaptive function. Cross-population comparisons of haplotype homozygosity found evidence of positive selection in a region proximal to the chloroquine resistance transporter gene (pvcrt-o), which has been implicated in chloroquine resistance. The genomic patterns in Ethiopia highlight adaptations of potential public health concern in an endemic setting with moderately high and stable transmission within and between districts.

Chagas disease can lead to cardiac dysfunction or fatal arrythmias. while these manifestations occur more frequently in geographic areas more prevalent with the TcI/II circulating genetic strains of Trypanosoma cruzi; strain-specificity in the expression of disease is influenced by yet-to-be-determined factors. To define the cardiomyocytes differential transcriptomic responses resulting from infection with different T. cruzi strains and explore their relationships with pathogenesis, HL-1 cardiomyocytes were infected with TcI/II or TcVI T. cruzi trypomastigotes. RNA was serially isolated post-infection for microarray analysis. Enrichment analyses of differentially expressed genes highlighted the most affected biological pathways. We found that Oxidative stress-related GO terms, 'Hypertrophy model', 'Apoptosis', and 'MAPK signaling' pathways (all with $p < 0.01$) were upregulated as a common response to all T. cruzi strains. 'Glutathione and one-carbon metabolism' pathway, and 'Cellular nitrogen compound metabolic process' GO term (all with $p < 0.001$) were upregulated exclusively in the cardiomyocytes infected with the TcI/II strains. Upregulation in the oxidative stress-related and hypertrophic responses are shared hallmarks with myocarditis caused by Coxsackie virus, another inflammatory cardiac pathology. Nitrogen metabolism upregulation and Glutathione metabolism

affection may represent the relation of nitrosative stress and poor oxygen radicals scavenging in the pathophysiological events that lead of chagasic cardiomyopathy.

5629

GENOME ASSEMBLY OF TRYPANOSOMA CRUZI TULAHUEN STRAIN REVEALS HIGHLY ABUNDANT TRANSPOSABLE ELEMENTS ASSOCIATED WITH VARIABLE SURFACE PROTEINS

Jill Hakim, Sneider Gutierrez, Edith Malaga, Anshule Takyar, Robert Gilman, Monica Mugnier

Johns Hopkins University, Baltimore, MD, United States

Trypanosoma cruzi is the causative agent of Chagas disease, which causes 10,000 deaths per year. Despite the high mortality caused by the disease, there is very little whole genome data available for the parasite. T. cruzi has a highly repetitive genome with multiple copies of variable surface proteins, as well as large scale structural genome rearrangements, which makes resolving whole genomes incredibly challenging. Even laboratory strains frequently used in biomedical research do not have publicly available genomes. Using long read Nanopore sequencing, we have generated a high-quality, partially phased whole genome assembly of the hybrid Tulahuen strain, a Type VI strain commercially available from ATCC. Using automated tools and manual curation we have annotated transposable elements in our newly assembled genome. We report a genome with 35% simple repeats, 24% surface proteins, and 22% transposable elements. Moreover, we find that regions with transposable elements are significantly enriched for surface proteins, and that on average surface proteins are closer to transposable elements compared to other coding regions. This finding supports an interesting possible mechanism for diversification of surface proteins that involves mobile genetic elements such as transposons.

5630

ZOONOTIC HEPATITIS E VIRUS GENOTYPE 3 STRAIN DETECTED IN A CAPYBARA (HYDROCHOERIS HYDROCHAERIS) FECAL SAMPLE, BRAZIL

Adriana Luchs[1], Lia Cunha[1], Lais S. Azevedo[1], Vanessa CM Silva[1], Marcilio F. Lemos[1], Antonio C. da Costa[2], Adriana P. Compri[1], Yasmin França[1], Ellen Viana[1], Fernanda Malta[3], Roberta S. Medeiros[1], Raquel Guiducci[1], Simone G. Morillo[1], Michelle S. Gomes-Gouvea[2], Deyvid Amgarten[3], João Renato R. Pinho[3], Regina C. Moreira[1]

[1]Adolfo Lutz Institute, Sao Paulo, Brazil, [2]Institute of Tropical Medicine of São Paulo, Sao Paulo, Brazil, [3]Hospital Israelita Albert Einstein, Sao Paulo, Brazil

Hepatitis E virus (HEV) is an emerging zoonotic pathogen associated to relevant public health issues. HEV was reported infecting wild rats worldwide; however the importance of wild rodents as potential HEV reservoirs or their zoonotic role is still unknown. Capybara (Hydrochoerus hydrochaeris) is the world´s largest rodent species distributed throughout South America and known to carry potentially zoonotic agents. The aim of this study was to investigate the HEV species Paslahepevirus balayani's presence in free-living capybaras inhabiting urban parks in São Paulo state, Brazil. Molecular characterization and phylogenetic analysis of positive samples was also undertaken. A total of 337 fecal samples collected during 2018-2020 were screened for HEV using RT-qPCR and confirmed by conventional nested RT-PCR targeting ORF1 and ORF2 regions. HEV genotype and subtype was determined combining Sanger and next generation sequencing. HEV was detected in one specimen (0.3%) collected in 2019, and assigned as HEV-3f. Phylogenetic analysis of ORF1 and ORF2 regions revealed that Brazilian capybara HEV-3f strain are closely related to European swine, wild boar and human strains (90.7%-93.2% nt), suggesting an interspecies transmission. Molecular epidemiology of HEV is poorly investigated in Brazil and so far, subtype 3f has only been reported in swine, hampering that more robust conclusions could be drawn from the phylogenetic analysis. This is the first detection of HEV in capybaras stool samples. Nevertheless, this data must be treated with caution once identification of HEV in these mammals may not necessarily be associated with natural infection and not indicate that these animals play a role in the HEV transmission. Capybaras are continuously exposed to fecal-borne viruses as these animals display semi-aquatic habit and are living in human-animal interface environments. The implementation of systematic molecular surveillance of HEV in the One Health concept, including human, wildlife, domestic pigs, wild boars and environment samples are vital to elucidate HEV-3 subtype's role and circulation in the country.

5631

ASYMPTOMATIC VISCERAL LEISHMANIASIS PREVALENCE IN MILITARY WORKING DOGS COMPARED TO SOLDIERS DEPLOYED TO IRAQ

Jennifer A. Safko[1], Sorana Raiciulescu[2], Fernanda Fortes De Araujo[2], Edward Breitschwerdt[3], Naomi E. Aronson[2]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]North Carolina State University, College of Veterinary Medicine, Raleigh, NC, United States

Visceral leishmaniasis (VL) is a zoonotic, vector-borne disease that poses a significant health risk to canines and humans. We previously reported 19.5% of American Soldiers deployed to Iraq had asymptomatic visceral leishmaniasis (AVL). Canines are the main reservoir of Leishmania infantum, a cause of VL. Military Working Dogs (MWDs) deploy worldwide and work closely with Soldiers. The aim of this study was to determine the rate of AVL in MWDs that deployed to Iraq to assess their infection and transmission risk. This retrospective study examined records of 104 MWDs that deployed to Iraq from the Remote Online Veterinary Record database and the Federal Records Center between 2005-2022. Banked pre- and post-deployment serum and whole blood samples were obtained from the Department of Defense Food Analysis and Diagnostic Laboratory. Leishmania diagnosis was confirmed using the canine rk39 Rapid test, Indirect Fluorescent Antibody (IFA) Assay and quantitative polymerase chain reaction (PCR). The prevalence of canine VL was 2.9% (n=3/104); 2 were PCR positive, one seroconverted. Sand fly prevention was documented in 65% of the MWDs. Of the 3 MWDs that tested positive, 66% (n=2) did not receive sand fly prevention and 100% were asymptomatic for VL. The odds of a VL positive test were 4.1 times more likely in a MWD without sand fly prevention compared to MWDs with sand fly prevention. Iraq-deployed human American Soldiers who were tested for AVL responded on a survey that 138/200 (69%) rarely or never used insect repellent, 14 (7%) worked or handled MWDs, 18 (9%) cared for local dogs, and 75 (37.5%) reported others had local dogs in their unit. Despite canines being the main host and reservoir for L. infantum, MWDs deployed to Iraq had a considerably lower VL prevalence than their human counterparts. Increasing the use of sand fly prevention in leishmaniasis endemic areas may better protect Soldiers deployed to these regions."The opinions and assertions expressed herein are those of the author(s) and do not reflect the official policy or position of the Uniformed Services University of the Health Sciences or the Department of Defense."

United States, [3]Wildlife Veterinary Consulting, LLC, Fort Collins, CO, United States, [4]Colorado State University, Department of Biology, Fort Collins, CO, United States

Bats are increasingly singled out as a source of disease pathogens, what is not very clear though, is how the pathogens cross over to humans. Using camera traps in caves with known bat colonies, we monitorg the inner cave usage by bats and other vertebrates to establish if there may be a possible connection that could provide an avenue for dispersal of bat borne pathogens to humans or human environments.Our preliminary results suggest continuous bat activity in their cave day roost, which we suspect is a result of presence of some other vertebrate in the cave roost that stirs the bats to fly around.From camera trap data so far our results show: --The continued presence of bats in the cave during the day but not in the night.-A total six other vertebrate species (including humans) present in the cave when the bats were also in the cave.-No direct depredation on bats by the other vertebrates in the cave.We continue to monitor the cave use by the bats and the other vertebrates to understand what the potential risk for pathogen (if ever they are determined to be in the bats) spill could be. Two of the species (genet and civet are carnivores that could potentially eat bats). The porcupine and giant rats could potentially feed on guano while all species are exposed to aerosols in the cave. Two species the Porcupine and the Giant rats are species commonly hunted for meat by some members of the local community.

5633

ACTIVITY PATTERNS OF INSECTIVOROUS BATS IN THE MT. ELGON REGION-UGANDA: IMPLICATION FOR DISEASE SURVEILLANCE

Micheal Mutebi[1], Robert M. Kityo[1], Betty Nalikka[1], Kalani M. Williams[2], Nalukenge P. Lilian[1], Rebekah C. Kading[2], Natalie Wickenkamp[2], Emma Harris[2], Kevin Castle[3], Tanya Dewey[4], Matovu Ben[1], Siya Aggrey[1]

[1]Makerere University Department of Zoology Entomology and Fisheries Sciences, Kampala, Uganda, [2]Colorado State University, Department of Microbiology, Immunology, and Pathology, Fort Collins, CO, United States, [3]Wildlife Veterinary Consulting, LLC, Fort Collins, CO, United States, [4]Colorado State University, Department of Biology, Fort Collins, CO, United States

Uganda is home to over 110 bat species, including 77 species of insectivorous bats playing critical roles of economic importance including pest insect consumption, pollination and fertilizer production. However, some bat species are associated with highly pathogenic viruses such as coronaviruses, paramyxoviruses and filoviruses which pose public health concerns. It has always been a suppositional debate on how these viruses spill-over to humans. In Uganda, humans visit caves to collect manure, minerals and use caves as shelter for both humans and their animals. This poses a spill-over risk of potentially infectious agents. We are currently undertaking a five-year project in Kapchorwa district for bio-surveillance of potential zoonotic pathogens in bats. Where we also investigate the ranging patterns of bats in this region using LOTEK GPS tags to understand how far bats move from their cave roosts to forage and how this behaviour can predispose human communities to disease outbreak should a bat be carrying pathogens; this method has proven useful in providing insightful information on bat species' movements. However, the small size of some insectivorous bats makes it impossible to have a GPS tag mounted on their back. Furthermore, the nocturnal and elusive behaviours of bats make it difficult to capture them for tagging. Using SM4+ bat Detectors we passively monitored the presence and activity of the insectivorous bats species to inform our understanding of the bat community composition in the region. Our results so far point to over 14 species recorded in human occupied landscapes; two of which species have previously shown positive tests for infectious pathogens. We continue collecting long term acoustic data to enable our understanding of seasonal bat activities to enable us draw inferences on the potential risk of spill over of pathogens to humans. Overall, our research underscores the importance of continued research into bat ecology and zoonotic disease surveillance, and will also lead to generating a national library of acoustic for insectivorous bats which shall be point of reference for further studies of bats in Uganda.

5634

FACTORS INFLUENCING BAT BORNE VIRAL PATHOGENS PREVALENCE AND SPILL OVER IN UGANDA: IMPLICATIONS FOR ONE HEALTH INITIATIVES

Benard Matovu[1], Robert M. Kityo[1], Lillian Nalukenge[1], Betty Nalikka[1], Michael J. Mutebi[1], Aggrey Siya[1], Rebekah C.[2], Harris Emma[2], Williams Kalani[2], Kevin Castle[3], Tanya Dewey[2]

[1]Makerere university, Kampala, Uganda, [2]Colorado State University, Fort Collins, CO, United States, [3]Wildlife Veterinary Consulting, LLC, Fort Collins, CO, United States

Although bats have been implicated as one of the key reservoirs for various viral pathogens, and also reported to participate in spill over of pathogens; there is still no very clear evidence at what critical threshold of events the viral pathogens spill to humans. And yet, like many other vertebrates, bats have lived with several types viruses for a long time. In recent decades emerging diseases such as Ebola, Murburg, SARS and other viral zoonotic diseases linked to bats, continue to pose critical global public health concerns. This research attempts to contribute to the body of knowledge of how and when bat-borne viral pathogens could spill. Using systematic review, predictive modelling approaches, and active sampling of bat species to detect viral pathogens in different cave roosts of Mt Elgon region, Uganda; we seek to identify the critical threshold levels of spatiotemporal, ecological, physiological and anthropogenic determinants that might trigger bat-borne virus spill over. We suggest that an interplay of several factors at given thresholds might be responsible for triggering likelihood for spillovers. We predict the critical level of interaction of environmental factors, seasonal factors, bat community ecology, bat population size, roost characteristics, roost fidelity by bats, human activity in the caves, and bat physiological stress; that would influence the occurrence and spill over of bat-borne viral pathogens. This in turn is linked to the implications for One health initiatives.

5635

PURCHASE, CONSUMPTION, AND OWNERSHIP OF CHICKENS AND CHICKEN PRODUCTS AMONG HOUSEHOLDS IN MAPUTO, MOZAMBIQUE: A CROSS-SECTIONAL STUDY

Kayoko Shioda[1], Frederica Lamar[2], Jhanel Chew[3], Hermógenes N. Mucache[4], Karen Levy[5], Matthew Freeman[3]

[1]Boston University, Boston, MA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Emory University, Atlanta, GA, United States, [4]Universidade Eduardo Mondlane, Maputo, Mozambique, [5]University of Washington, Seattle, WA, United States

Poultry farming provides an important source of income and nutrition in low- and middle-income countries; however, chickens are also the major reservoir for zoonotic enteropathogens, which are responsible for a significant burden of foodborne illness. Informal food systems pose the risk of transmission of enteropathogens from poultry to humans. To gain a better understanding of the potential exposure to enteropathogens of poultry origin, we conducted one of the first cross-sectional, population-based surveys assessing chicken consumption, purchase, and rearing practices using in Maputo, Mozambique. We surveyed 570 households using a structured questionnaire between May and June 2021. We found that about half of 570 households purchased broiler chicken meat (weighted n=250, 44.8%) and eggs (263, 46.5%) in the week leading up to the survey. The most common location where households purchased broiler chicken meat was corner stores (i.e., small stores on streets) (weighted n=141, 56.7%), followed by informal wet markets (43, 17.5%) and directly from farmers (45, 16.8%). Of 570 households, 97 (16.4%) reported that they raised live chickens at the time of the survey. Chicken feces were observed on the floor or ground at 49 (51%) of these 97 households. Of 39 households with children under five that raised chickens, 11 (28%) reported that their children take care of live chickens. Of 570 households, 58 (10.2%)

reported that they applied chicken litter compost to their gardens. Our study highlights the importance of implementing food safety measures, particularly at informal food systems that often do not have access to adequate hygiene facilities, to control foodborne illnesses resulting from poultry products.

HIGHLY PATHOGENIC AVIAN INFLUENZA A (H5N1) IN MARINE MAMMALS AND SEABIRDS IN PERU

Mariana Leguia[1], Alejandra Garcia-Glaessner[1], Breno Muñoz-Saavedra[1], Diana Juarez[1], Patricia Barrera[1], Carlos Calvo-Mac[2], Javier Jara[3], Walter Silva[3], Karl Ploog[3], Lady Amaro[3], Paulo Colchao-Claux[4], Marcela M. Uhart[5], Martha I. Nelson[6], Jesus Lescano[3]

[1]Genomics Laboratory, Pontificia Universidad Catolica del Peru, Lima, Peru, [2]EpiCenter for Emerging Infectious Disease Research, Lima, Peru, [3]Servicio Nacional Forestal y de Fauna Silvestre, Ministerio de Desarrollo Agrario y Riego del Peru, Lima, Peru, [4]Wildlife Conservation Society Peru, Lima, Peru, [5]One Health Institute, School of Veterinary Medicine, University of California, Davis, CA, United States, [6]National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health, Bethesda, MD, United States

Highly pathogenic avian influenza (HPAI) A/H5N1 viruses (lineage 2.3.4.4b) are rapidly invading the Americas, threatening wildlife, poultry, and potentially evolving into the next global pandemic. In November 2022 HPAI arrived in Peru, causing massive pelican and sea lion die-offs. We report complete genomic characterization of HPAI/H5N1 viruses in five species of marine mammals and seabirds (dolphins, sea lions, sanderlings, pelicans and cormorants) sampled since November 2022. All Peruvian viruses belong to H5N1 lineage 2.3.4.4b, but they are 4:4 reassortants where 4 genomic segments (PA, HA, NA and MP) position within the Eurasian lineage that initially entered North America from Eurasia, while the other 4 genomic segments (PB2, PB1, NP and NS) position within the American lineage (clade C) that was already circulating in North America. These viruses are rapidly accruing mutations as they spread south. Peruvian viruses do not contain PB2 mutations E627K, D701N, K702R previously linked to mammalian host adaptation and enhanced transmission, but at least 8 novel polymorphic sites warrant further examination. This report of HPAI A/H5N1 in marine birds and mammals from South America highlights an urgent need for active local surveillance to manage outbreaks and limit spillover into humans of a highly pathogenic avian influenza strain with clear pandemic potential.

EXPLORING THE HEALTH SEEKING BEHAVIOR OF SNAKEBITE VICTIMS AND COMMUNITY PERCEPTIONS IN THE VOLTA AND OTI REGIONS OF GHANA

Rita Suhuyini Salifu, Martin A. Ayanore, Agani Afaya

University for Health and Allied Sciences,, Ho, Ghana

Snakebite envenoming is a neglected tropical disease with incidence growing globally. In Ghana, an average estimate of 9,600 snakebites occur annually ,thus a serious public health concern . Mortality rates due to snakebites are linked to delays in reporting for treatment in health facilities. This study examined health-seeking behavior of snakebite victims and community members perceptions on treatments for victims of snakebites in the Volta and Oti Regions of Ghana. This was a mixed method study conducted in ten (10) selected communities in both the Volta Region (Ho Municipality, Kpando Municipality) and Oti Region (Nkwanta North District, Jasikan District). Communities were selected using purposive sampling techniques, and data were analyzed using the Statistical Package for the Social Sciences (IBM SPSS) version 26.0. Descriptive statistics was used for sociodemographic characteristics. Bivariate and multivariate binary logistic regression analysis was used to assess the factors associated with health-seeking behavior among participants. A total of 397 participants were included in the study, with a snakebite incidence of 15.9% among community members. The mean age of participants was 39.56 (±SD=14.78) with 42.3% being females and 57.7% males. This study found 43% of participants had a family member who had been bitten by a snake. The multivariate logistic regression analysis showed that those whose family members previously experienced snakebites were more likely (aOR=1.93, 95%CI:1.25-2.99) to seek health care than those who had never experienced snakebites. In Kpando,54% of participants attended the traditional healer as their first treatment for snakebites while Jasikan, Kpassa and Ho showed higher attendance to health facilities with the highest (86%) in Ho. There exists high awareness among community members about seeking healthcare from a health facility however they still believe in using traditional remedies or visiting the traditional healer. Culturally appropriate interventions that seek to improve the health-seeking behavior of snakebite victims within the community will be imperative to reduce the burden.

Although leptospirosis is suspected to be common in rural Tanzania, data are limited. We sought to determine leptospirosis prevalence, identify infecting Leptospira serogroups, and investigate risk factors for leptospirosis in a rural area of Tanzania where pastoralist animal husbandry practices and sustained livestock contact are common. We enrolled patients at Endulen Hospital, Arusha Region, Tanzania, presenting with a history of fever within 72 hours, or a tympanic temperature of ≥38.0°C. We administered structured questionnaires covering recent symptoms, animal-related activities, and livestock health. Serum samples were collected at enrolment and 4-6 weeks later and were tested using microscopic agglutination testing with 20 Leptospira serovars from 17 serogroups. Leptospirosis was defined as a ≥four-fold rise in antibody titer between acute and convalescent serum samples, or a reciprocal titer ≥400 in either sample. Leptospira seropositivity was defined as a single reciprocal antibody titer ≥100 in either sample. The predominant reactive serogroup was that with the highest titer. We explored risk factors for leptospirosis and Leptospira seropositivity using multivariable logistic regression modelling. Of 229 participants, 99 (43.2%) were male and the median (range) age was 27 (0, 78) years. Participation in at least one livestock related activity was reported by 160 (69.9%). We identified 18 (7.9%) cases of leptospirosis, with Djasiman 8 (44.4%) and Australis 7 (38.9%) the most common predominant reactive serogroups. Overall, 69 (31.1%) participants were Leptospira seropositive and the most common predominant reactive serogroups were Icterohaemorrhagiae 21 (30.0%), Djasiman 19 (27.1%), and Australis 17 (24.3%). Milking cattle (OR 6.27, 95% CI 2.24-7.52) was a risk factor for leptospirosis, and milking goats (OR 2.35, 95% CI 1.07-5.16) was a risk factor for Leptospira seropositivity. Leptospirosis caused nearly one in

twelve hospitalizations with febrile illness in this predominantly pastoralist population. Interventions that reduce risks associated with milking livestock may reduce human leptospirosis.

5639

CRIMEAN CONGO HEMORRHAGIC FEVER IN TANZANIA: RELEVANCE OF ONE HEALTH APPROACH ON UNDERSTANDING THE EPIDEMIOLOGY OF A PRIORITY ZOONOSIS

Ray Kayaga[1], Gabriel Shirima[1], Lugano Kusiluka[2], Sarah Cleaveland[3], Blandina Mmbaga[4], Felix Lankester[5], Furaha Mramba[6], William B. Karesh[7], Elichilia Shao[8], Tito Kibona[9], Roger Hewson[10], Oliver Carnell[10], Brian Willett[3], Ryan Carter[3], Andrew Clarke[3], Julius Keyyu[11], Carlos Zambrana-Torrelio[7], Abdul Lukambagire[7], Nichar Gregory[7], Rebecca Bodenham[7], Johana Teigen[7], Melinda Rostal[7]

[1]Nelson Mandela African Institution of Science and Technology, Arusha, Tanzania, United Republic of, [2]Mzumbe University, Morogoro, Tanzania, United Republic of, [3]University of Glasgow, Glasgow, United Kingdom, [4]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [5]Washington State University, Washington, DC, United States, [6]Hester Biosciences Africa Limited, Kibaha, Tanzania, United Republic of, [7]EcoHealth Alliance, New York, NY, United States, [8]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [9]Global Animal Health, Arusha, Tanzania, United Republic of, [10]UK Health Security Agent, Porton Down, United Kingdom, [11]Tanzania Wildlife Research Institute, Arusha, Tanzania, United Republic of

The World Health Organization's Research and Development Blueprint lists Crimean-Congo hemorrhagic fever (CCHF) virus on their priority A list and hemorrhagic fever diseases are on the list of priority pathogens in Tanzania due to high risk to public health. A One Health approach is necessary to study CCHFV, a tick-borne zoonotic virus, that circulates between ticks and several vertebrate hosts without causing overt disease and thus can be present in areas without being noticed. A systematic sampling method is conducted across a gradient of different human disturbance levels such as pristine, pastoral and agro-pastoral areas in northern Tanzania to assess CCHF seroprevalence and prevalence in ticks, small mammals, cattle and people. More than a thousand ticks have been collected and identified thus far for virus detection by polymerase chain reaction (PCR). Five mainly genera of ticks have been collected and identified namely Rhipicephalus, Amblyomma, Hyalomma and Haemaphysalis. This One Health approach to sample people, cattle, small mammal and vector populations simultaneously will strengthen the study's power to identify associations among these populations as well as risk factors for virus exposure and circulation across the gradients of environmental disturbances. By One Health approach from this study we will be able to create research-based data on the epidemiology of CCHF virus in ticks, cattle, small mammals, people and risk factors associated with the virus exposure. Furthermore, with very limited data present on CCHF in Tanzania, findings from the study will be important in improving Tanzania's capacity to manage the risk of CCHF as well as making evidence-based prevention and control recommendations.

5640

ARPHILAKE CONSORTIUM COMBATING ANTIBIOTIC RESISTANCE IN PHILIPPINES' LAKES: ONE HEALTH UPSTREAM INTERVENTIONS TO REDUCE THE BURDEN

Ricardo Castellanos[1], Windell Rivera[2], Ana Pereira Do Vale[3], Paul Wigley[4], Stefanos Giannakis[5], Dylan R. Pillai[1]

[1]University of Calgary, Calgary, AB, Canada, [2]University of Philippines Diliman, Manila, Philippines, [3]University College Dublin, Dublin, Ireland, [4]University of Bristol, Bristol, United Kingdom, [5]Polytechnic University of Madrid, Madrid, Spain

Lakes are critical aquatic ecosystems and provide essential natural resources for populations in low-middle income countries like the Philippines. A growing concern has been the contamination of lakes with determinants conferring antimicrobial resistance (AMR) from animal and human sources. In particular, a growing literature supports that beta-lactam resistance is a burgeoning issue in Asian lakes and rivers. However, few interventions have been rigorously evaluated to determine if the impact of environmental contamination from hospitals and agriculture and livestock production can be reduced. Here, we propose specific interventions with pre- and post-evaluations to determine their impact on beta-lactam resistance. Following a One Health the ARPHILAKE consortium composed of partners from Canada, Spain, UK, Ireland, and the Philippines will: i) Conduct environmental monitoring to identify antimicrobials and antimicrobial resistance genes in Laguna Lake and surrounding areas for mitigation at point sources; ii) Enable feasible, economic, and effective treatment method for farm effluents and hospital wastewater based on solar light; iii) Determine the AMR profile of bacteria isolated from backyard farms animals in the Laguna Lake area and exame the driver for antimicrobial use and prescription in the veterinary setting; and iv) Implement point of care rapid testing for key antimicrobial resistant organisms and antimicrobial stewardship in selected hospitals. This is the first project following a One Health approach conducted in the Philippines to reduce the risks of AMR in the lake environment. The outcomes of this project will serve as starting points to replicate the interventions in other lakes in the Philippines and other Southeast Asian countries. The scientific data produced will be used to promote awareness on AMR through community participation and develop government policy interventions. Such knowledge and interventions to reduce antimicrobials and AMR bacteria will help preserve the lake that provides economic services to the lakeshore communities.

5641

PARASITOLOGICAL RISK AT THE INTERFACE WILDLIFE-DOMESTIC ANIMALS IN NAZINGA RANCH, BURKINA FASO

Awa Gneme[1], Victor Dapougdi Thiombiano[1], Yamba Sinare[2], Siriki Roland Konate[1], Emmanuel Midibahaye Hema[3]

[1]Université Joseph KI-ZERBO, Ouagadougou, Burkina Faso, [2]Ecole Normale Supérieure, Koudougou, Burkina Faso, [3]Université de Dedougou, Dedougou, Burkina Faso

Changes in land use, habitat fragmentation, habitat loss, climate change and human population growth are modulating the relationships between humans, domestic animals and wildlife. These events have led to the emergence of new infectious diseases. While some of these diseases have their origins in wildlife, wild populations are also exposed to pathogens from humans and their animals. This situation impacts wildlife conservation. This study aim to highlight parasites at the wildlife and domestic animals interface in Burkina Faso. Fresh droppings of wild and domestic animals were collected in the Nazinga Ranch and its surroundings following transects line that cover the conservation zone, the buffer zone, the hunting zone and the interface of the park where wild, domestic animals and humans can meet. Coprological analyses were done to isolate parasites. A total of 76 samples belonging to eight different species of mammals were collected. These animals were Antelopes (Hippotragus equinus), Defassa Cobs(Kobus ellipsiprymnus defassa), Buffon's Cobs (Kobus kob), Domestic Goat (Capra hircus), Bushbuck (Tragelaphus scriptus), the Elephant (Loxodonta africana), Warthog (Phacochoerus africanus), and Ox (Bos taurus). The prevalence of parasites was 75.0% for Nematoda, 13.16% for Trematoda, 68.42% for Cestoda and 26.31% for Protozoans. At the interface, the droppings encountered belonged to Loxodonta africana, Capra hircus and Bos taurus with infection rate of 66.6%, 64.5% and 100% respectively. While Capra hircus carried only Tapeworms, Bos taurus and Loxodonta africana had several parasites in common such as genera of Haemonchus, Cooperia, Taenia, Moniezia, Eimeria. A total of 16 species of parasites were encountered during this study. This parasite richness and the modes of dissemination of these parasites show that there is a high risk of transmission between wildlife, domestic animals and humans in this area. The high prevalence of infection in elephants is therefore, another threat to this species, which is already heavily impacted by human-elephant conflicts.

5642

CHARACTERISING PSYCHOSOCIAL IMPACT OF TUBERCULOSIS AND THE SOCIAL SUPPORT NEEDS FOR PEOPLE WITH TUBERCULOSIS IN INDONESIA

Ahmad Fuady[1], Bustanul Arifin[2], Ferdiana Yunita[3], Saidah Rauf[4], Agus Fitriangga[5], Agus Sugiharto[1], Finny Fitry Yani[6], Helmi Suryani[7], I Wayan Gede Artawan Eka Putra[8], Muchtaruddin Mansyur[1], Tom Wingfield[9]

[1]Universitas Indonesia, Jakarta, Indonesia, [2]Universitas Hasanuddin, Makassar, Indonesia, [3]Universitas Gunadarma, Depok, Indonesia, [4]Politeknik Kesehatan Kemenkes Maluku, Maluku, Indonesia, [5]Universitas Tanjungpura, Pontianak, Indonesia, [6]Universitas Andalas, Padang, Indonesia, [7]Universitas Jambi, Jambi, Indonesia, [8]Universitas Udayana, Bali, Indonesia, [9]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Stigma towards people with TB (TB-Stigma) is a crucial challenge to TB elimination and is associated with other TB psychosocial consequences. We evaluated TB-Stigma, depression, quality of life (QoL), and psychosocial support needs among people with TB in Indonesia. In seven provinces of Indonesia, from February to November 2022, we interviewed adults diagnosed with drug-susceptible (DS)-TB (a) receiving treatment at public facilities, (b) receiving treatment at private facilities, (c) lost to follow up (LTFU) to treatment, and (d) receiving TB retreatment. We used our previously-validated Indonesian TB-Stigma Scale to measure TB-Stigma, Patient Health Questionnaire-9 (PHQ-9) to assess depression, EQ-5D-5L to quantify QoL, and additional questions to determine needs for psychosocial support. We applied general linear models and regression analyses to identify factors associated with TB-Stigma and correlations between TB-Stigma, depression, and QoL. Of 612 study participants, 60.6% experienced moderate TB-Stigma. TB-Stigma scores were higher among people receiving treatment at private facilities (adjusted B (aB)=2.48;0.94-4.03), those LTFU (aB=2.86;0.85-4.87), males (aB=1.73;0.59-2.87), losing or changing job due to TB (aB=2.09;0.31-3.88) and living in a rural area. Participants experienced mild-to-moderate (36%) and moderately severe to severe (6%) depression. Experiencing TB-Stigma was associated with moderately severe to severe depression (adjusted odds ratio=1.23;1.15-1.32), and higher combined stigma and depression levels were associated with lower QoL. Participants had a high unmet need of peer support including peer-to-peer emotional support (52%), peer-to-peer education (63%), and peer-led group counselling (78%). In conclusion, there is a sizeable and intersecting burden of TB-Stigma and depression, which is associated with lower QoL. Participants reported a substantial unmet need for psychosocial support from peers. Based on these findings, we are now co-designing a community-based peer-led psychosocial intervention for TB-affected people in Indonesia.

5643

DIAGNOSTIC ACCURACY OF THE NOVA TUBERCULOSIS TOTAL ANTIBODY RAPID TEST FOR DETECTION OF PULMONARY TUBERCULOSIS AND INFECTION WITH MYCOBACTERIUM TUBERCULOSIS

GIDEON NSUBUGA

Makerere University, Kampala, Uganda

The NOVA Tuberculosis Total Antibody Rapid Test is a commercially available lateral flow serological assay that is intended to be used as an aid in the diagnosis of tuberculosis. We conducted a study to estimate diagnostic accuracy of this assay for diagnosis of active pulmonary tuberculosis disease and for detection of M. tuberculosis infection. This study used existing frozen plasma specimens that had been obtained previously from consenting adults whose tuberculosis status was rigorously characterized. The investigational assay was performed in a single laboratory by laboratory staff specifically trained to conduct the assays according to the manufacturer's procedures. In addition, intensity of the test band was subjectively assessed. Plasma specimens from 150 participants were tested. All testing attempts yielded a determinate result of either positive or negative. For diagnosis of active pulmonary tuberculosis disease, test sensitivity and specificity were 40.0% (20/50, 95% confidence interval [CI] 27.6% to 53.8%) and 85.0% (95% CI 76.7% to 90.7%), respectively. For detection of M. tuberculosis infection, test sensitivity and specificity were 28.0% (95% CI 20.5% to 37.2%) and 86.0% (95% CI 73.8% to 93.0%), respectively. Among the 35 positive tests, no statistically significant band intensity trend was found across participant groups (p=0.17). Study findings do not support a role for the NOVA Tuberculosis Test in current tuberculosis diagnostic algorithms.

5644

EXPLORING THE POTENTIAL OF A SALIVA-BASED, RNA-EXTRACTION-FREE PCR TEST FOR THE MULTIPLEXED DETECTION OF KEY RESPIRATORY PATHOGENS

Orchid M. Allicock[1], Tzu-Yi Lin[1], Katherine Fajardo[1], Devyn Yolda-Carr[1], Claire Laxton[1], Maikel S. Hislop[1], Jianhui Wang[2], Denora Zuniga[2], William Platt[2], Beth Tuhoy[3], **Anne L. Wyllie**[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Yale School of Medicine, New Haven, CT, United States, [3]Yale University, New Haven, CT, United States

Efforts to control and monitor transmissible infectious diseases rely on large-scale screening initiatives. The use of saliva as a non-invasive sample type could alleviate bottlenecks encountered in mass testing strategies in community settings. Having extensively demonstrated saliva as sensitive for the detection of SARS-CoV-2, we sought to validate this approach for other common respiratory pathogens. From May-July 2022, de-identified saliva samples were collected from consenting adults ≥18 years of age with respiratory symptoms (New Haven, CT, USA). Saliva samples from SARS-CoV-2-negative individuals were stored at -80ºC until further processing in the research laboratory. We modified our RNA-extraction-free SARS-CoV-2 PCR test for multiplexed detection of four additional key respiratory viruses ("SalivaDirect+"): influenza A, influenza B, RSV and hMPV and for singleplex testing for pneumococcus. Sample stability was tested after storage at +4°C, room temperature (~19°C) and 30°C for 72 hours. We confirmed a limit of assay detection at 4 copies/µl for each virus target. From 804 saliva samples tested with SalivaDirect+, 17 (2.1%) tested positive for one of the viruses targeted, with 7 (0.9%) positive for influenza A, 4 (0.5%) positive for RSV, and 6 (0.7%) samples positive for hMPV. No sample tested positive for influenza B. For influenza A and RSV, detection by SalivaDirect+ was comparable to testing following RNA extraction but detection of hMPV was less sensitive. We confirmed that virus detection remained stable at +4°C, room temperature and 30°C for up to 72 hours. In singleplex testing, 87 (10.8%) samples tested positive for pneumococcus. By testing saliva samples from symptomatic, SARS-CoV-2-negative individuals we detected respiratory viruses which were otherwise missed in testing focused solely on SARS-CoV-2. Being less invasive and less resource-intensive than other sample types, saliva-based testing can lead to more equitable and sustainable testing and surveillance programs. As a result, saliva can bolster the public health response, particularly in low-resource and remote environments.

PREVALENCE OF NASOPHARYNGEAL CARRIAGE OF MACROLIDE RESISTANCE-ASSOCIATED ERYTHROMYCIN RIBOSOME METHYLASE (ERM) GENES AMONG HEALTHY CHILDREN AND ADULTS IN A PERI-URBAN COMMUNITY IN LIMA, PERU

Cara E. Charnogursky[1], Ana I. Gil[2], Lucie Ecker[2], Rubelio Cornejo[2], Stefano Rios[2], Mayra Ochoa[2], Bia Peña[2], Omar Flores[2], Claudio F. Lanata[2], Carlos G. Grijalva[1], Leigh M. Howard[1]

[1]Vanderbilt University Medical Center, Nashville, TN, United States, [2]Instituto de Investigación Nutricional, Lima, Peru

Erythromycin ribosome methylase (erm) genes, which confer macrolide resistance, are commonly detected in healthcare settings. Yet, their prevalence among healthy individuals in the community is unknown. Here

we provide an initial assessment of erm nasopharyngeal carriage in healthy children and adults. Nasopharyngeal swabs were systematically obtained at enrollment and weekly thereafter from children and adults enrolled in a household-based prospective cohort study in Lima, Peru. Samples were sequenced using the Illumina Respiratory Pathogen/ID AMR Panel to detect common respiratory bacteria and antimicrobial resistance genes. We defined 'any erm gene' (erm) as the detection of at least one of the specific erm gene classes. We compared the prevalence of erm carriage at enrollment among age groups (ages 0-4, 5-17, 18-44, and 45+ years) using the Fisher's exact test. There were 114 individuals were included in this analysis; 74% were female and median age was 24.2 years (IQR 4.6, 41.8). An erm gene was detected in 51 (44.7%) of individuals, most commonly ermC (15.8%) and ermB (7%). The prevalence of erm gene detection was high and similar among age groups: [0-4 years (19/33, 57.6%), 5-17 years (12/20, 60.0%), 18-44 years (11/34, 32.4%) and 45+ years (9/27, 33.3%) (p=0.056)]. These preliminary results indicate that erm genes were commonly detected in healthy community-dwelling children and young adults in Lima, Peru. Future analysis will assess changes in erm carriage over time, transmission among household members, and its clinical relevance.

5646

VACCINATION FOLLOWING THE EXPANDED PROGRAM ON IMMUNIZATION SCHEDULE COULD HELP TO REDUCE DEATHS IN CHILDREN UNDER FIVE HOSPITALIZED FOR PNEUMONIA AND SEVERE PNEUMONIA IN A DEVELOPING COUNTRY

Abu Sadat Mohammad Sayeem Bin Shahid, Tahmina Alam, Lubaba Shahrin, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Pneumonia is the leading cause of under-five mortality worldwide. An expanded programme on immunization (EPI) is one kind of evidence-based tool for controlling & even eradicating infectious diseases. This study aimed to explore the impact of EPI vaccination among children of 4-59 months hospitalized for pneumonia & severe pneumonia. Additionally, we evaluated the role of 10 valent pneumococcal conjugate vaccine alone on clinical outcomes in such children. In this retrospective chart review, children 4-59 months of age with the WHO defined pneumonia & severe pneumonia, admitted in the Dhaka Hospital of icddr,b between August`2013 & December`2017 who had the information on immunization as per EPI schedule by 4 months of age, were included in the analysis. Comparison was made between the children who were fully immunized & who were not immunized (consists of partial immunization and no immunization). A total of 4625 children had pneumonia & severe pneumonia during the study period. Among them, 2605 (56.3%) had information on immunization. Between them, 2195 (84.3%) were fully immunized by 4 months of age according to EPI schedule & 410 were not immunized. In log-linear binomial regression analysis, it has been revealed that immunization in children 4-59 months of age was associated with lower risk of diarrhea (p=0.033), severe pneumonia (p=0.001), anemia (p=0.026) & deaths (p=0.035). Importantly, the risk of developing severe pneumonia (1054/1570 [67%] vs. 202/257 [79%], p<0.001) and case-fatality-rate (57/1570 [3.6%] vs.19/257 [7.4%], p=0.005) were still significantly lower among those who were immunized with PCV-10 than those who were not. Under-five children immunized as per EPI schedule were at a lower risk of diarrhea, severe pneumonia, anemia & deaths, compared to unvaccinated children. In addition, PCV-10 was found to be protective against severe pneumonia & deaths in such children. The overall results underscored the importance of the continuation of immunization scrupulously adhering to EPI schedule to reduce the risk of morbidities & mortalities in such children, especially in resource-limited settings.

RESPIRATORY SYNCYTIAL VIRUS INFECTION IN CHILDREN ADMITTED TO A PEDIATRIC INTENSIVE CARE UNIT IN GHANA AMID COVID-19 PANDEMIC

Comfort Nuamah Antwi[1], Evangeline Obodai[1], Kwabena Osman[2], Jonas Kusah[2], Renate Visser[3], Yvette Lowensteyn[3], John Kofi Odoom[1], Bamenla Quarm Goka[4]

[1]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, [2]Department of Child Health, Medical School, College of Health Sciences, University of Ghana, Legon, Accra, Ghana, [3]Department of Pediatric Infectious Diseases and Immunology, Wilhelmina Children's Hospital, University Medical Center, Utrecht, Netherlands, [4]Department of Child Health, Medical School, College of Health Sciences, University of Ghana, Accra, Ghana

Respiratory Syncytial Virus (RSV) infection is a seasonal illness that affects about 97% of children by the age of 2 years. Although RSV infection can be life-threatening during the first year of life and is the leading cause of hospitalization in infants, there are limited data available on the burden of RSV in critically ill children to inform on the prevention and treatment of the disease with specific viral therapeutics. The current study assessed the burden of RSV among children aged less than 2 years in a pediatric intensive care unit (PICU) during the COVID-19 pandemic in Accra, Ghana. Children below the age of 24 months with severe respiratory tract infections who were admitted to the PICU of the Korle Bu Teaching Hospital were recruited with parental consent. Nasal swabs were obtained within 72 hours of admission and tested for RSV and Influenza virus using the ID NOW Point of care test machine at the PICU and then confirmed by real-time quantitative reverse transcription-polymerase chain reaction (RT-qPCR) at the Noguchi Memorial Institute for Medical Research. Samples were also investigated for the presence of other viral agents such as the SARS-Cov 2 virus. Twenty-eight children were enrolled from June to November 2021. RSV was confirmed in 9/28 (32%) of the children who were all below the age of 12 months. Among the RSV-positive group, infants <3 months old had a higher incidence of infection (67%, p<0.01). RSV A predominated 7/9 (78%) cases. One (1) patient each tested positive for Influenza virus and SARS-CoV-2. Two patients (22%) were preterm and 5 (56%) had congenital abnormalities. Besides supportive treatment, children were on antibiotics routinely per the PICU protocol. The average length of stay of patients at the PICU was 19.11 days and one (1) RSV death occurred. RSV remained an important cause of severe respiratory illness during the COVID-19 outbreak in Ghana. The PICU burden of RSV was heavy on infants during the first year of life. And there is a need for targeted interventions such as the introduction of vaccines against severe RSV disease.

The suboptimal nature of diagnostics leads to empirical broad-spectrum and tuberculosis treatment for most patients with respiratory illness in low-income settings, where also the aetiology is poorly described especially at the primary care level. Our ACT-TB Trial demonstrated that empirical broad-spectrum antibiotics do not add much diagnostic or clinical benefit for patients presenting to primary care. We hypothesized that the bulk of the respiratory symptoms may have been caused by respiratory viruses and atypical bacteria whose diagnostics are not readily available. To investigate the aetiology and prevalence of respiratory pathogens that are not traditionally investigated, we conducted a cross-sectional study including a random selection of patients from the ACT-TB trial participants (trial included: aged ≥18 years, attending primary care, unwell for at least 14 days, with cough, with no immediate indication for hospitalization). Participants provided nasopharyngeal swab samples and we used real-time-Polymerase Chain Reaction (Siemens® FTD 33kit) to detect pathogens. We included 297 participants (45% male), and the most common pathogens were Bordetella (87%), Klebsiella pneumoniae (77%), salmonella species (70%), HCoVHKU1 (57%), Haemophilus influenzae (56%), Chlamydia pneumoniae (54%), Human rhinovirus (49%), Haemophilus influenzae B (46%) Staphylococcus aureus (45%), and ICV (44%). Our preliminary results demonstrate the high prevalence of respiratory viruses and atypical bacteria, all of which are not covered by any of the antibiotics used for empirical therapy. This mismatch highlights the need for National tuberculosis and antimicrobial stewardship programs to improve diagnostic protocols and limit outpatient prescriptions of antibiotics. Future research and investment should focus on strengthening diagnostics for tuberculosis and other respiratory pathogens. At the conference, we hope to present additional analysis by TB status and clinical improvement status.

5649

PULMONARY-UROGENITAL TUBERCULOSIS: A DELAYED DIAGNOSIS

Fara Rahidah Hussin[1], Nor Shuhaila Shahril[2], Ummu Afeera Zainulabid[3], Najma Kori[4], Petrick Periyasamy[4]

[1]Tuanku Mizan Armed Forces Hospital, Kuala Lumpur, Malaysia, [2]Putrajaya Hospital, Kuala Lumpur, Malaysia, [3]International Islamic University, Pahang, Malaysia, [4]National University of Malaysia, Kuala Lumpur, Malaysia

Urogenital tuberculosis (TB) is responsible for one-third of cases of extrapulmonary TB and occurs in up to 20% of patients with pulmonary TB. We illustrate a diagnostic challenge in a case of pulmonary-urogenital TB with HIV infection. A 60-year-old woman with HIV infection diagnosed in May 2020 following an initial presentation of Escherichia Coli bacteremia complicated by HIV-related immune thrombocytopenic purpura. Computed tomography (CT)thorax revealed tree in bud in bilateral upper lobes with mild hydronephrosis of the right kidney compared to the left kidney. She underwent bronchoscopy and her TB work-up was negative. She was treated for latent TB with Isoniazid-based regime and commenced on antiretroviral therapy and prednisolone. She presented again in February 2023 following a 3-day history of fever with documented temperatures of 380C but no obvious source of infection. She had thrombocytopenia of 45X109/L but normal white cell count, renal and liver function. Her chest radiograph was normal. She was treated as occult sepsis with intravenous (IV) Ceftriaxone and IV Hydrocortisone with subsequent resolution of fever. She had recurrence of her fever with tenderness at right lumbar region after five days of Ceftriaxone. Her antibiotic was escalated to IV Meropenem. Ultrasound abdomen showed gross right hydronephrosis with pyonephrosis. Contrast-enhanced CT thorax and abdomen revealed multiple tree-in-bud nodules prominent in both upper lobes with multiple lung nodules. There were no cavitating lung lesions and enlarged mediastinal lymphadenopathy. There was right hydronephrosis with dilated pelvic-calyces, stenosed infundibulum and right mid ureteric stricture. She underwent a right nephrostomy with subsequent right ureteral stenting. Direct smear urine for acid fast bacilli was positive and Mycobacterium TB(MTB) GeneXpert was positive with indeterminate Rifampicin-resistant, pending urine MTB culture and sensitivity. Treatment with anti-TB medications was commenced, with steroid replacement. In conclusion, Urogenital TB can be missed in view of asymptomatic manifestation of hydronephrosis

PREVALENCE OF MALARIA-PNEUMONIA OVERLAP IN RURAL GAMBIA: NINE YEARS OF CLINICAL EXPERIENCE IN ENDEMIC AREA

Mohammad Ilias Hossain, Malick Ndiaye, Babila G Lobga, Golam Sarwar, Grant Mackenzie

MRC Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia

Globally malaria and pneumonia account for almost 40% of the mortality in under-five children in sub-Saharan Africa. Respiratory distress is a common feature of severe falciparum malaria in both children (40%) and adults (25%). We aimed to assess the prevalence of malaria and radiological pneumonia (RP) overlap and the proportion of children with these overlapping who truly require pneumonia treatment along with malaria management. The surveillance population included in the Upper River Region (URR) all Basse Health and Demographic Surveillance System (BHDSS) residents aged 2-59 months. Nurses screened all outpatients and inpatients at Basse Health Centre (BHC) of a referral health facility during the surveillance period from May 2008 to December 2016. Clinicians then applied criteria for patient investigation and treatment was provided based on national guidelines. Rapid diagnostic tests (RDT) for malaria were done from August to December during malaria transmission season. During the population-based surveillance, 22061 patients aged 2-59 months were registered at BHC. We found 1178 cases (6.65%, 1178/17705) of malaria positive, and 1649 cases (12.32%, 1649/13389) of RP. We identified 1198 cases (97.6%, 1198/1227) of RP patients had malaria negative, and 29 cases (2.4%, 29/1227) of RP had malaria positive. 472 cases (5.3%, 472/8858) of no RP had malaria positive and 8386 cases (94.7%, 8386/8858) of no RP had malaria negative. A total of 59.1% (696/1178) (95% CI 56 to 62) of malaria cases had respiratory findings. Among malaria positive and negative cases, we identified 106 cases of Invasive Bacterial Diseases (IBD), Streptococcus pneumoniae, 8 cases of Salmonella spp, and 8 cases of Staphylococcus aureus. Radiological pneumonia is uncommon with malaria RDT-positive. An empiric antibiotic is not indicated with respiratory symptoms and malaria RDT positive. Point of care test for radiological pneumonia/bacterial pneumonia is needed to target antibiotic therapy in children with respiratory symptoms and malaria RDT positive.

5651

DETERMINANTS OF TUBERCULOSIS OUTCOMES DURING THE COVID-19 PANDEMIC AT A REFERRAL HOSPITAL IN RURAL HAITI

Elie Saintilien[1], Aaron Richterman[2], Medgine St-Cyr[1], Louise Claudia Gracia[1], Inobert Pierre[1], Moise Compère[1], Ahmed Elnaiem[3], Dyemy Dumerjuste[1], Louise C. Ivers[4]

[1]St. Boniface Hospital, Fond-des-Blancs, Haiti, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]Brigham and Women's Hospital, Boston, MA, United States, [4]Massachusetts General Hospital, Boston, MA, United States

Tuberculosis (TB) is a major public health threat in Haiti, with an estimated annual incidence of 159/100,000. Little is known about determinants of TB outcomes in Haiti since 2020, when multiple events coincided that were likely to impact TB care: the Covid-19 pandemic, progressively worsening national political and security crises, and an earthquake in 2021. To address this, we conducted a prospective cohort study at the St. Boniface Hospital (SBH), a rural referral center in Southern Haiti. Eligibility criteria included: age greater than 18 years, clinically suspected or microbiologically confirmed (by smear, NAAT, or culture) TB, receiving standard first-line TB treatment. We excluded patients with drug-resistant TB and those who had already received at last 7 days of treatment. We administered a baseline

questionnaire, collected baseline and outcome clinical data, and analyzed laboratory samples. We assessed risk factors for unfavorable outcomes (death, treatment failure, loss to follow up) using multivariable logistic regression models. We enrolled 250 patients (37% female) between May 2020 and January 2023, with a median age of 35 years (IQR 25-45). Only 13% had completed secondary education and 20% reported no formal education. Food insecurity was common (55%), and the median probability of poverty (< $1USD/day) was 45% (IQR 28-77). The median time to reach the hospital was 120 minutes (IQR 90-180), the median duration of symptoms prior to presentation was 12 weeks (IQR 4-20), 40% had undernutrition, and 54% met criteria for depression. Of participants with finalized outcome data, 179 (80%) had a favorable outcome, and 10 (4%) died. Independent risk factors associated with unfavorable outcome were age (Adjusted Odds Ratio [AOR] 1.03 per year, 95% CI 1.01-1.06), travel time (AOR 1.07 per 10 minutes, 95% CI 1.02-1.12) and being a smoker (AOR=2.77, 95% CI 1.21-6.32). Our findings highlight factors that can be deleterious in the course of TB, and can serve as a guide to improve intervention strategies (for example, community outreach for patients living far from health facilities) aimed at minimizing the impact of TB.

5652

SHORT VERSUS LONG DURATION MACROLIDE TREATMENT FOR RESPIRATORY TRACT INFECTIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF EFFICACY, SAFETY, AND ADHERENCE OUTCOMES

Maureen Tayamika Ndalama[1], Solomon Mequanente Abay[2], Anteneh Belete[3], Anthony Emeritus Chirwa Emeritus Chirwa[1], Laure Ngaunfo[4], Katherine L. Fielding[5], Elizabeth L L. Corbett[1], Titus Divala[6]

[1]Malawi Liverpool Wellcome Clinical Programme, Blantyre, Malawi, [2]Department of Pharmacology and Clinical Pharmacy, School of Pharmacy, Addis Ababa University, Addis Ababa, Ethiopia, [3]Addis Ababa University, College of Health Sciences, Center for Innovative Drug Development and Therapeutic Trials for Africa (CDT-Africa), Addis Ababa, Ethiopia, [4]University of Limerick, Limerick, Ireland, [5]TB Centre, London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Helse Nord Tuberculosis Initiative (HNTI), Kamuzu University of Health Sciences (KUHES), Blantyre, Malawi

Respiratory tract infections are a cause of death and disability worldwide. Management involves a course of antibiotics for a period of 7-14 days, however prolonged exposure to antibiotics may lead to the development of antimicrobial resistance. We compared the efficacy, safety, and adherence of short-course with long-course macrolide treatment for respiratory tract infections. We conducted a systematic review and meta-analysis by searching the Embase, MEDLINE, and Cochrane Central Register of Controlled Trials for randomized controlled trials published from inception to 25 August 2021. Studies that recruited patients with respiratory infections and reported treatment outcomes of at least two macrolide antibiotics given for different durations were eligible. We used Rob 2.0 to assess the quality of studies and a random effects meta-analysis to estimate effects and 95% confidence intervals. 2695 articles were retrieved. 9 randomized controlled trials published between 1984 and 2005 involving 2900 participants from 27 countries in Africa, America, Asia, Europe, and Oceania were eligible for inclusion. The target respiratory infections were tonsillo-pharyngitis, atypical pneumonia, acute exacerbation of chronic bronchitis, community-acquired pneumonia, sinusitis and upper respiratory tracts infection, community-acquired acute maxillary sinusitis and Group A beta-haemolytic streptococcal tonsillitis/pharyngitis. Short duration treatment did not differ from long duration treatment with respect to efficacy assessed using incidence of treatment failure (RR= 0.88, 95% CI= 0.71-1.09). The proportion of treatment non-adherent participants was also similar between short and long duration macrolide groups (RR= 0.85, 95% CI=0.65, 1.11). The risk of adverse events was lower among patients in the shorter duration group compared to the longer duration group (RR =0.88, 95% CI=0.80, 0.96). We found that short duration treatment is as effective and safe as long duration treatment. This result should inform the design of antibiotic dosages to preserve the lifespan amid the dryness of the product development pipeline.

5653

PREVALENCE OF EXTRA-PULMONARY TUBERCULOSIS IN AFRICA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Semira Hailu[1], Cameron Hurst[2], Griffin Cyphers[1], Stefan Thottunkal[3], David Harley[1], Kerri Viney[4], Adam Irwin[1], Clare Nourse[1]

[1]University of Queensland, Brisbane, Australia, [2]Molly Wardaguga Research Centre, Brisbane, Australia, [3]The Australian National University, Canberra, Australia, [4]Karolinska Institutet, Sweden, Sweden

Mycobacterium tuberculosis primarily causes pulmonary disease. Disease in other organs is called extra-pulmonary tuberculosis (EPTB). The burden of EPTB is not well quantified in TB endemic countries such as those in sub-Saharan Africa. This study aimed to quantify the burden of EPTB via a systematic review of the prevalence of EPTB in African countries. Studies were retrieved by searching five databases; 84 studies published between 1990 and 2020 were included. The studies described the prevalence of EPTB among TB patients (53 studies) or patients with conditions other than TB including HIV (12), meningitis (3), renal failure (3) and other comorbidities some of which are cancer (9). The focus of the meta-analysis was on EPTB among TB patients (53 studies). Meta-analysis was performed in the 53 studies (198,781 participants) using a random-effects model to estimate pooled prevalence of EPTB. Meta regression was used to explore possible explanations for the heterogeneity observed, according to regions and time period. The pooled prevalence of EPTB among TB patients was 24% (95% CI 21- 28%). There was substantial heterogeneity in prevalence for the five African regions. The Eastern region had the highest prevalence with 30% (95% CI 26-35%) and the lowest prevalence was in Western Africa, 17% (95% CI 10-27%). There was no significant difference in the prevalence of EPTB when compared between 3 ten-year time periods. This systematic review and meta-analysis provides an estimate of the prevalence of EPTB in TB patients in Africa.

5654

NEUTRALIZING ANTIBODIES TO SARS-COV-2 IN A ONE YEAR CROSS-SECTIONAL STUDY IN KISUMU COUNTY, KENYA

Esther A. Omuseni

KEMRI-USAMRD-A/K, KISUMU, Kenya

Neutralizing antibodies (NAbs) to SARS-CoV-2 spike protein are a good predictor of protective immune response to coronavirus disease 2019 (COVID-19). In this cross-sectional study carried out at Kombewa, Kisumu County, Kenya during Alpha, Delta and Omicron waves, total of 1,385 subjects were enrolled, out of which 827 (61.7%) had NAbs. The mean magnitude of NAbs increased over the successive waves (0.90 U/mL at alpha, 1.80 U/mL at Delta and 5.7 U/mL at Omicron), while frequency of SARS-CoV-2 by qPCR progressively declined; 25% at alpha, 3% at Delta and 10% at Omicron. Further analyses are recommended to dichotomize NAbs emanating from SARS-CoV-2 infections and those from vaccinations.

5655

PREDICTION OF DISEASE OUTCOME USING A DEFINITE CUT-OFF VALUE IN CHEST X-RAY SCORING, OBSERVATION FROM A RESOURCE LIMITED COVID-19 TREATMENT FACILITY

Shamsun Nahar Shaima[1], Md, Ahshanul Haque[1], Monira Sarmin[1], Sharika Nuzhat[1], Yasmin Jahan[2], Lubaba Shahrin[1], Fariha Bushra Matin[1], Rehnuma Tabassum Timu[1], Abu Sadat Mohammad Sayeem Bin Shahid[1], Mohammod Jobayer Chisti[1], Tahmeed Ahmed[1]

[1]icddrb, Dhaka, Bangladesh, [2]Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan

Evaluation of potential outcomes of COVID-19 affected pneumonia patients using radiological imaging chest computed tomography (CT) scans, may not be conceivable in low-resource settings. Thus, this study aimed to evaluate the performance of chest X-ray (CXR) scoring in

predicting the disease severity and outcomes of adults hospitalized with COVID-19. This was a retrospective chart analysis consuming data from COVID-19-positive adults who had CXR availability and were admitted to a temporary COVID-19 unit in Bangladesh from 23rd April 2020 to 15th November 2021. We reviewed baseline CXR, clinical data, and blood test results of all enrolled patients. At least one clinical intensivist and one radiologist combinedly reviewed each admission CXR for the presence of consolidation, ground-glass opacities, reticular opacities, and pleural effusion. CXR scoring varied from 0 to 8, depending on the area of lung involvement with 0 indicating no involvement and 8 indicating ≥75% involvement of both lungs. The receiver operating characteristic curve (ROC) was used to determine the optimum CXR cut-off score for predicting fatal outcomes. Out of 263 COVID-19 affected adults, a total of 218 (82.9%), with a mean age of 53.52 ± 16 years, were included in the study. The ROC demonstrated the optimum cut-off as ≥3 and ≥5 for disease severity and death, respectively. In multivariate logistic regression analysis, a CXR score of ≥3 was found to be independently associated with disease severity (aOR, 8.70; 95% CI, 3.82, 19.58, p <0.001) and a score of ≥5 with death (aOR, 16.53; 95% CI, 4.74, 57.60, p <0.001) after adjusting age, sex, antibiotic usage before admission, history of fever, cough, diabetes mellitus, hypertension, total leukocytes count, and C-reactive protein (CRP). Using CXR scoring derived cut-off values at admission might help to prompt identify the COVID-19 affected adults with different severity of pneumonia and who are at risk of severe disease and mortality. This may help to initiate early and aggressive management of such patients as well as reduce their fatal outcomes.

Pneumococcus is a leading cause of pneumonia globally. Pneumococcal conjugate vaccines (PCV) protect against vaccine-serotype disease and nasopharyngeal carriage, leading to reduced transmission and herd protection. Kenya introduced 10-valent Synflorix (PCV10GSK: serotypes 1, 4, 5, 6B, 7F, 9V, 14, 18C, 19F and 23F) in 2011 and switched to Pneumosil (PCV10SII: 1, 5, 6A, 6B, 7F, 9V, 14, 19A, 19F and 23F) in 2022. PCV13 includes PCV10GSK types plus 3, 6A and 19A. We examined pneumococcal carriage prevalence and serotype distribution among predominantly outpatient severe acute respiratory illness (SARI) cases, to understand persistence of PCV10GSK serotypes 6-9 years after introduction and to assess serotype coverage of PCV10SII and PCV13. We leveraged ongoing SARI surveillance at two sites (Kibera, urban informal settlement in Nairobi and Asembo, rural western Kenya) collecting nasopharyngeal swabs for culture from patients of all ages meeting a standardized SARI case definition. Culture-positive isolates were serotyped by conventional multiplex PCR and/or Quellung. From January 2017 to April 2020, 3,067 patients in Asembo and 838 in Kibera had swabs collected and tested. Pneumococcal carriage prevalence was 43.0% (n=1,320) and 58.1% (n=487) in Asembo and Kibera, respectively; among children aged <5 years it was 63.3% (606/958) and 78.3% (144/184), respectively. Among 1,298 (97.7%) serotyped isolates from Asembo, most common serotypes were 3 (n=148), 6A (n=108), 35B (n=90), 19F (n=69) and 19A (n=58); among 482 (96.7%) serotyped isolates from Kibera, most common were 3 (n=50), 35B (n=29), 11A (n=26), 16F (n=22), 13 (n=20) and 19A (n=18). The prevalence of carriage with PCV10GSK, PCV10SII and PCV13 serotypes was 5.2%, 10.4%, and 15.5%, respectively in Asembo, and 8.9%, 11.8%, and 18.7% in Kibera; among children <5 years it was 8.0%, 16.6%, 21.2% in Asembo and 9.2%, 17.4%, and 26.6% in Kibera. Pneumococcal carriage in SARI is not reflective of etiology yet provides insight into circulating serotypes. PCV10GSK serotypes, most notably 19F, persisted up to 9 years after vaccine introduction. PCV10SII will offer broader serotype coverage.

HUMAN IMMUNODEFICIENCY VIRUS INFECTION AND DIABETES MELLITUS IN PEOPLE WITH TUBERCULOSIS IN ODISHA, INDIA

Sidhartha Giri[1], Priyanka Sahu[1], Srikanta Kanungo[1], Himadri Bhusan Bal[2], Sanghamitra Pati[1]

[1]ICMR Regional Medical Research Centre Bhubaneswar, Bhubaneswar, India, [2]FIND India, New Delhi, India

This study evaluated the burden of human immunodeficiency virus (HIV) infection and diabetes mellitus (DM) in tuberculosis (TB) cases from Odisha, India, during 2019, and its impact on the TB treatment outcome. The study utilized data on TB patients of Odisha during 2019, from the NIKSHAY portal, the health management information system of TB in India. This is a retrospective observational registry-based cohort study, which evaluated a linkage between socio-demographic predictors, clinical diagnostic and treatment predictors, time of treatment predictors, and co-morbidity with TB. Data were retrieved electronically in Microsoft-Excel and analysis was done using STATA 16. Data for 47831 TB cases of Odisha was extracted from the Nikshay application for 2019. The highest prevalence (31.1%, 14863/47831) of TB was observed among young participants aged 15-30 years, whereas the prevalence was least among children <14 years (4.4%, 2124/47831). Of the 47831 TB cases, 7.6% (3659/47831) had DM, along with TB. 1.2% (571/47831) had HIV along with TB, while only 0.08% (37/47831) had both DM and HIV along with TB. 88.2% (3148/3569) of cases with DM and TB had a favorable outcome, compared to 82.3% (449/541) of cases with HIV and TB. People with TB who did not have DM had a significantly higher favorable outcome (OR 1.6, 95% CI 1.5-1.8) compared to those with TB and DM. Similarly, TB cases who did not have HIV infection had a significantly higher favorable outcome (OR 2.4, 95% CI 1.9-3.0) compared to those with TB and HIV. In conclusion, our study showed that presence of DM and/or HIV in TB patients had an impact on the TB treatment outcome.

5658

SCHISTOSOMAL CIRCULATING ANODIC ANTIGEN CLEARANCE IN PRESCHOOL AGED CHILDREN FROM THE PIP (PRAZIQUANTEL IN PRESCHOOLERS) TRIAL

Gloria Kakoba Ayebazibwe[1], Andrew Edielu[1], Susannah Colt[2], Emily L. Webb[3], Patrice A. Mawa[1], Hannah W. Wu[3], Govert J.van Dam[4], Paul Corstjens[4], Racheal Nakyesige[1], Jennifer F. Friedman[2], Amaya L. Bustinduy[3]

[1]Medical Research Council/Uganda Virus Research Institute and London School of Hygiene and Tropical Medicine Uganda Research Unit, Entebbe, Uganda, [2]Lifespan Center for International Health Research, Providence, Rhode Island, RI, United States, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Leiden University Medical Centre, Leiden, Netherlands

Circulating Anodic Antigen (CAA) is known to be specific to schistosomiasis and is assessed using the highly sensitive Up-Converting reporter Particle Lateral Flow (UCP-LF) CAA assay. The CAA assay is an important tool in determining worm burden hence is relevant in estimating treatment efficacy and reinfection rates. Limited data on CAA clearance after praziquantel (PZQ) treatment is available in Preschool Aged Children (PSAC). As part of the PIP trial, a phase II trial exploring different PZQ dosing regimens in children aged 12-47 months in Uganda, we present findings assessing clearance by measuring CAA in urine before and four weeks after PZQ treatment. The trial enrolled PSAC infected with Schistosoma mansoni as diagnosed by stool Kato-Katz (KK) living on the shores of Lake Albert,

Uganda. Schistosomal CAA was analyzed at baseline and at four weeks post treatment along with egg count by KK. 348 participants were enrolled to the trial with a median age of 36 months (IQR 28.0 – 42.0) and 51% of the participants were male. KK infection intensities at baseline were categorised as light (56.9%), medium (24.0%) and heavy (19.1%). Median CAA concentration was 154.8pg/ml (IQR 41.3 - 673.8) at baseline and 4pg/ml (IQR 0.2 - 58.0) at four weeks post treatment. Overall, there was a marked reduction in CAA levels at four weeks post treatment with 41% 'antigen cure' (95% CI 35.4 – 46.7). In comparison, parasitological cure based on KK was 91% (95% CI 86.9 – 94.2) for the 300 participants with complete CAA data. Out of those who showed parasitological cure at four weeks, 52.8% (95% CI 46.4 – 59.3) were still CAA positive but with relevantly reduced CAA concentrations. Findings demonstrate expected high egg reduction after PZQ treatment but with poor 'antigen cure', raising concerns of residual untreated infection in this trial setting. The disparity in diagnostic clearance is likely due to the poor sensitivity of KK at low egg burdens.

GAPS IN BEDSIDE PROTOCOLS AND POLICIES FOR MANAGEMENT OF FEMALE GENITAL SCHISTOSOMIASIS IN ENDEMIC SOUTH AFRICA AND NON-ENDEMIC NORWAY

Iris Kamilla Ottosen[1], Stina Josefine Karlsen[1], Patricia Ndhlovu[2], Solrun Søfteland[3], Saloshni Naidoo[4], Motshedisi Sebitloane[5], Pamela S. Mbabazi[6], Santiago Martinez[7], Takalani Nemungadi[4], Themba Ginindza[4], Fortunate Shabalala[8], Sakhile Masuku[8], Svein Gunnar Gundersen[9], Pavitra Pillay[10], Myra Taylor[4], Eyrun Floerecke Kjetland[3]

[1]Faculty of medicine, University of Oslo, Oslo, Norway, [2]BRIGHT Academy, Ugu District, South Africa, [3]Departments of Infectious Diseases and Global Health, Norwegian Centre for Imported and Tropical Diseases, Ullevaal, Oslo University Hospital, Oslo, Norway, [4]Discipline of Public Health Medicine, Nelson R Mandela School of Medicine, College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa, [5]Discipline of Gynaecology, Nelson R Mandela School of Medicine, College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa, [6]World Health Organization, Geneva, Switzerland, [7]University of Agder, Kristiansand, Norway, [8]University of Eswatini, Faculty of Health Sciences, Mbabane, Swaziland, [9]Department for Global Development and Planning, University of Agder, Kristiansand, Norway, [10]Durban University of Technology, Durban, South Africa

Female genital schistosomiasis (FGS) is a prevalent gynaecological disease amongst women and girls in schistosomiasis-endemic parts of Africa. However, it is often misdiagnosed as a sexually transmitted disease or cervical cancer. FGS may cause abnormal vaginal discharge, infertility, paediatric genital symptoms, and may increase the susceptibility to HIV. The diagnosis entails cervicovaginal examination. WHO recommends praziquantel 40-60 mg/kg as a single dose. To adequately serve immigrants and travellers, health professionals in non-endemic countries should also be aware of FGS as a differential diagnosis. This literature study sought to explore current grey literature for FGS and gaps in patient management protocols in endemic South Africa and non-endemic Norway. Healthcare professionals in ten institutions provided access to bedside protocols used in their clinical practice. The heads of the cervical cancer screening programmes in both countries provided National Department of Health policies and protocols. Management protocols from private practitioners and hospitals were not included for practical reasons. Ten management and policy documents from each country, such as the national Standard Treatment Guidelines in South Africa and the regional hospital guidelines in Norway, were examined. This included reading through the relevant chapters, word searching and exploring the references. No guidelines mentioned FGS in the diagnosis or management of abnormal vaginal discharge, bloody discharge, infertility, or cancer. In order to change the current under-diagnosis, misdiagnosis and mismanagement of women it is imperative that the recommendations for diagnosis and treatment of FGS are included in healthcare policies and management protocols. Further research and collective action are needed to address the gaps in national guidelines and bedside protocols in both countries.

Detection of Schistosoma DNA in gynaecological samples by real-time polymerase chain reaction (qPCR) is considered to be the reference laboratory test for the diagnosis of Female Genital Schistosomiasis (FGS). However, qPCR is expensive and needs highly trained technicians. Loop-mediated amplification (LAMP) is a more field-friendly isothermal DNA amplification procedure, but it still requires electrically powered equipment. Here we validated an S. haematobium-specific Sh-LAMP procedure and tested a fully instrument-free isothermal DNA amplification and detection procedure by using a novel low-cost and reusable T-cup device. Specific primers were selected based on published assays, targeting the ribosomal intergenic spacer region of S. haematobium. Technical validation of the Sh-LAMP was performed using 20 negative controls, including DNA extracts of soil transmitted helminths and S. mansoni, and a 10-fold dilution series (100-10-3) of DNA extracted from a single S. haematobium egg (n=4). For clinical validation, the Sh-LAMP was used on 125 DNA samples extracted from swabs of cervicovaginal lesions of a previous FGS study in Madagascar. Results were compared with the cycle threshold value (Ct) of the standard ITS-2 targeting qPCR. The T-cup performance was evaluated in a representative sub-selection (n=10) of Sh-LAMP positive clinical samples. Single S. haematobium egg DNA up to a 10-2 dilution and a Ct<35 were all Sh-LAMP positive. The specificity was found to be excellent (100%). In the clinical samples Sh-LAMP showed comparable results with the qPCR, with 35.2% and 33.6% positives, respectively, and a concordance of 79.2% (99/125). Most false-negatives were seen in the qPCR positive samples with a Ct≥35 (5/7), while Sh-LAMP detected 14 additional cases missed by qPCR. The T-cup was found to be a very user-friendly method, but it missed 1 of the 10 Sh-LAMP positive samples. The Sh-LAMP was found to be a suitable alternative to qPCR for the diagnosis of FGS in gynaecological samples, with high potential for the T-cup as a fully instrument-free DNA amplification device for point-of-care diagnosis in low-resource settings.

POPULATION LEVEL IMPACT OF NOVEL DRUGS TARGETING JUVENILE SCHISTOSOMES ON CONTROL AND ELIMINATION OF SCHISTOSOMIASIS

Benjamin J. Singer[1], Minoli Daigavane[1], Sophia Tan[1], Mireille Gomes[2], Thomas Spangenberg[2], Jason R. Andrews[3], Isaac I. Bogoch[4], Nathan C. Lo[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Global Health Institute of Merck, Ares Trading S.A., a subsidiary of Merck KGaA, Eysins, Switzerland, [3]Stanford University, Stanford, CA, United States, [4]University of Toronto, Toronto, ON, Canada

Praziquantel (PZQ), the standard drug for schistosomiasis, has minimal activity against juvenile schistosomes (within 6 weeks of infecting humans) and imperfect cure rates. The effect of treatment-resistant juvenile schistosomes and imperfect PZQ clearance on transmission dynamics of Schistosoma is unknown. We model the population level effects of novel drug candidates targeting both juvenile and adult schistosomes on schistosomiasis control programs in various settings, which can guide drug development decisions. We created an individual-based dynamic mechanistic model of S. mansoni transmission that simulates mass drug

administration programs using novel drugs. The model simulates low, medium, and high prevalence settings using data from SCORE trials, and explicitly models juvenile and adult schistosomes for each infected person. We simulated five years of annual mass drug administration with: i) 1-dose PZQ (40 mg/kg; per WHO guidelines); ii) 2-dose PZQ (6 weeks apart); and iii) novel drug with activity against juvenile and adult schistosomes. Treatment parameters for PZQ were calibrated to literature values (84% and 88% egg reduction for 1- and 2-dose PZQ), and novel drug efficacy was varied. We assumed 75% coverage. In a low prevalence setting (baseline 15%), 1-dose PZQ, 2-dose PZQ, and a novel drug (PZQ-equivalent activity against adult worms plus juvenile activity) led to 1.0%, 0.8%, and 0.8% prevalence at year 5, respectively. In a high prevalence setting (baseline 50%), 1-dose PZQ, 2-dose PZQ, and a novel drug led to 9.0%, 8.0%, and 7.4% prevalence at year 5, respectively. Increased efficacy of a novel drug against adult schistosomes compared to PZQ (+25% potency) had larger effects on prevalence reduction than comparable activity against juvenile schistosomes. A novel drug that can kill both adult and juvenile schistosomes with higher efficacy will have measurable public health gains compared to PZQ alone. A novel drug will have larger effects in high prevalence settings and small relative reductions in near elimination settings. Targeting juveniles is generally less important than increasing efficacy against adults.

5662

DEVELOPMENT OF ANTIGEN-BASED MULTIPLEX IMMUNODIAGNOSTICS FOR TWO PREDOMINANT SCHISTOSOMA PARASITES IN SUB-SAHARAN AFRICA

Oyetunde T. Oyeyemi, **Lisa M. Shollenberger**
Old Dominion University, Norfolk, VA, United States

Schistosomiasis is a disease of poverty that is highly prevalent in Sub-Saharan African countries. Cross-reacting proteins in Schistosoma mansoni (Sm) and S. haematobium (Sh) have been alluded to pose diagnostic challenges in the development of serological diagnostics. Proteins specific to these two parasites can leverage diagnostic challenges associated with cross-reactivity and the development of a multiplex diagnostic tool for the two parasites. The aim of this study is to identify protein markers from S. mansoni and S. haematobium for concurrent diagnosis of the two parasites. High-quality protein extracts were prepared from the eggs [(soluble egg antigen (SEA) and adult worms (Schistosoma worm antigens (SWA)] of S. haematobium and S. mansoni. The diagnostic performance of the proteins was evaluated using a quantitative ELISA method with sera obtained from S. mansoni-infected mice. The immunoreactive proteins in the helminths were identified by conventional Western blot analyses and the specific protein markers for concurrent diagnosis of the two parasites were confirmed by double-binding Western blot analyses. Sm SEA gave the best diagnostic performance (Sensitivity (SS) = 1.00, Specificity (SP) = 0.96, AUC = 0.96). Sh SEA slightly performed better in diagnosing S. mansoni infection (SS = 0.96, SP = 0.87, AUC = 0.95) compared to Sm SWA (SS = 0.91, SP = 0.95, AUC = 0.93). Diagnostic protein markers of size 100 kDa in Sh SWA, > 250 kDa (Sh SEA), 25-37 kDa (Sm SWA), and 50-150 kDa (Sm SEA) were specific for the concurrent diagnosis of S. mansoni and S. haematobium. This study showed the plausibility of developing multiplex immunodiagnostic tools for S. mansoni and S. haematobium. Ongoing studies with 2D Western blots and LC-MS seek to identify novel biomarkers for operational diagnosis of these two Schistosoma species simultaneously.

5663

BASELINE SEROPREVALENCE OF SCHISTOSOMA IN ZAMBIAN WOMEN ENROLLED IN A COHORT STUDY (THE ZIPIME WEKA SCHISTA STUDY)

Bronwyn Neufeld[1], Olimpia Lamberti[1], Helen Kelly[1], Rhoda Ndubani[2], Nkatya Kasese[2], Emily Webb[1], Beatrice Nyondo[2], Barry Kosloff[2], Jennifer Fitzpatrick[2], Bonnie Webster[3], Maina Cheeba[2], Helen Ayles[2], J.Russell Stothard[4], Kwame Shanaube[2], Amaya Bustinduy[1]
[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]Natural History Museum, London, United Kingdom, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Schistosomiasis, a disease caused by the waterborne parasite Schistosoma (S.) spp., continues to present a significant public health problem across sub-Saharan Africa. Schistosoma seroprevalence surveys provide an opportunity for the assessment of the burden of schistosomiasis in low-prevalence areas. This study aimed to assess Schistosoma seroprevalence in women as part of an ongoing cohort study and identify potential risk factors across two communities (Livingstone and Kafue) in Zambia using a field-applicable assay. Community health workers recruited women into the Zipime Weka Schista study through home visits and obtained genital self-swabs, urine samples, rapid tests for HIV and Trichomonas vaginalis (Tv), and administered a questionnaire. Venous blood was obtained at a follow up clinic visit. Serological testing was performed for the detection of antibodies to soluble egg antigen (SEA) using the IVD SEA-ELISA. Urine microscopy was conducted for the detection of S. haematobium (Sh) eggs in urine. Testing for High-Risk Human Papillomavirus (HR-HPV) was performed with Gene Xpert. Descriptive statistics were used to analyse sociodemographic characteristics and logistic regression was conducted to explore associations with other infection parameters. A total of 601 serum samples were analysed. Overall prevalence of egg-patent Sh was 5.7% (34/592). Approximately one third of participants (35.8%, 216/601) were found to be Schistosoma seropositive. Seroprevalence was higher in Livingstone than Kafue (40.1% vs. 32.0%, p=0.053). Seropositive participants were more likely to report daily water contact during childhood (p=0.006). Most seropositive participants had no Sh eggs observed in urine (90.0%, 188/209) suggesting chronic exposure. No crude or adjusted associations between Schistosoma seropositivity and any sexually transmitted infection were found including HR-HPV, HIV and Tv. Further visual and molecular genital testing for female genital schistosomiasis is ongoing and will refine our estimates.

5664

DEVELOPMENT OF AN ELISA TO DETECT ANTIBODY TO SCHISTOSOMA JAPONICUM INFECTION USING A BACTERIAL EXPRESSED RECOMBINANT ANTIGEN SJ10.3

Maurice Terrell Royal[1], Saima Chavenet[2], Sylvia Ossai[1], William Secor[1], Sukwan Handali[1]
[1]Center for Disease Control, Decatur, GA, United States, [2]Gwinett School of Mathematics Science and Technology, Gwinett, GA, United States

Schistosoma japonicum is a trematode parasite endemic in China, the Philippines, and parts of Sulawesi, Indonesia. Traditional diagnosis is based on identifying S. japonicum eggs in fecal samples using microscopy; however, diagnosis by microscopy requires trained personnel to make and read slides and has low sensitivity in light infections. Antibody detection for serological diagnosis can be useful to indicate schistosome infections in individuals who have traveled to schistosomiasis endemic areas, for mapping in control programs, and when attempting to assess interruption of transmission or perform surveillance. We selected protein Sj10.3 based on its homology to an S. mansoni antigen (Sm10.3) and S. haematobium antigen (Sh-SAP-1) that were identified by epitope library selection and peptide array screening. Using GenBank to obtain the sequence, we synthesized the Sj10.3 gene and expressed it as a GST fusion protein using a bacterial expression vector. The protein was purified using

glutathione magnetic beads and confirmed as reactive with sera from persons with S. japonicum infection using immunoblot. After optimization of the ELISA, we evaluated the assay performance using an S. japonicum serum panel obtained from WHO that consisted of 242 negative and 340 positive samples. These sera were confirmed positive by S. japonicum adult microsomal antigen immunoblot, the current CDC serological reference assay. Based on this serum panel, the assay's sensitivity and specificity are 91% and 99%, respectively. Planned validation studies include assay evaluation against a panel of potential cross-reactive sera such as other trematode infections, including paragonimiasis, fascioliasis, clonorchiasis, and opisthorchiasis. Availability of a recombinant antigen specific for schistosome infections improves the ability of control programs to map endemic areas, evaluate interruption of transmission, and perform surveillance for schistosomiasis in several Asian countries.

5665

URINARY HPV ANALYSIS AS A COMPLEMENTARY DIAGNOSTIC TEST AMONG WOMEN AT RISK FOR CERVICAL CANCER AND FEMALE GENITAL SCHISTOSOMIASIS

Pavitra Pillay[1], Hashini N. Galappaththi-Arachchige[2], Myra Taylor[3], Borghild B H Roald[4], Eyrun F. Kjetland[5]

[1]Department of Biomedical and Clinical Technology, Faculty of Health Sciences, Durban University of Technology, Durban, South Africa, [2]Faculty of Medicine, University of Oslo, Oslo, Norway, [3]Discipline of Public Health Medicine, University of KwaZulu-Natal, Durban, South Africa, [4]Department of Pathology, Oslo University Hospital, Oslo, Norway, [5]Norwegian Centre for Imported and Tropical Diseases, Department of Infectious Diseases, Oslo University Hospital, Oslo, Norway

The triad of HIV, cervical cancer and Female Genital Schistosomiasis (FGS) is found mainly in Africa. FGS is a neglected disease that is associated with HIV and is often misdiagnosed as cervical atypia. Most at risk are young women, aged 15 and above, constituting almost 3 million of the South African (SA) population. They may have limited access to healthcare and gynaecological investigations, may be reluctant to undergo a gynaecological examination, and are high at risk for this triad of diseases. The present study sought to compare HPV DNA in urine and cervico-vaginal lavage samples and explore their association with cytology results (Pap smears) and urinary Schistosoma haematobium microscopy results. The study was conducted among 220 young women aged 16-23 years of age from rural high schools in KwaZulu-Natal, South Africa. HPV DNA analysis was done in urine and vaginal lavage. Cytology samples were analysed for squamous cell atypia and urine microscopy was used for the identification of Schistosoma ova. The participants reported to have been sexually active from 17 years of age (SD=1.39). Schistosoma ova were found in 46 (20.9%) of the participants and the HIV prevalence was 43 (19.5%). Cervical cell atypia was detected in 120 (54.5%) of these young women. HPV DNA was detected among in 133 (60.5%) of the urine samples and in 168 (76.8%) of the cervico-vaginal lavage samples ($p < 0.001$). Using cervico-vaginal lavage as a gold standard, HPV PCR DNA urine analysis had a sensitivity of 75.15% and a specificity of 88.24%. There was no association between the HPV DNA in urine and cervico-vaginal lavage and cytology or urinary schistosomiasis results, respectively. It was also found that the young women who were HIV positive were 2,5 times more at risk for HPV in urine/vaginal lavage than those who were HIV negative. Urine has the potential of being optimized as a less invasive, alternative test for HPV among this young adolescent population at risk. In light of the diagnostic challenges urinary HPV testing might be a sustainable solution for targeted intervention among this neglected group.

5666

POPULATION PHARMACOKINETICS OF PRAZIQUANTEL IN PRE-SCHOOL AGE CHILDREN PARTICIPANTS IN THE PRAZIQUANTEL IN PRESCHOOLERS (PIP) TRIAL

Bonniface Obura[1], Andrew Edielu[2], Emily Webb[3], Jennifer Unsworth[1], Ana Jimenez-Valverde[1], Patrice Mawa[2], Amaya L. Bustinduy[3], Jennifer Friedman[4], Shampa Das[1]

[1]University of Liverpool, Liverpool, United Kingdom, [2]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Alpert Medical School of Brown University, Providence, RI, United States

Praziquantel (PZQ) remains the drug of choice for treatment of schistosomiasis, a major neglected tropical disease with over 250 million people infected globally; children bear more than 50% of the disease burden. However, limited pharmacokinetic (PK) data is available to guide dosing of PZQ in children. The objective of this study was to establish and describe the population PK of PZQ in pre-school age children. Children aged 1 to 4 years old with Schistosoma mansoni infection were enrolled into a clinical trial and randomised to receive either 40mg/kg or 80mg/kg dose of PZQ during the study. The doses were split into two and administered 3 hours apart (i.e. 40mg/kg and placebo; 40mg/kg and 40mg/kg). PK samples were collected at four time points; 1.5, 3, 4, and 6 hrs post dose. Plasma concentrations of PZQ enantiomers (R- and S-PZQ) were quantified using a liquid chromatography – tandem mass spectrometry (LC-MS/MS) assay. A hundred and ninety children (54.2% males) were enrolled with a mean age of 33 (± 9.23) months. There was significant variability in the plasma concentration profile of both R and S enantiomers. The plasma concentrations of both enantiomers were quantified up to 6 hours post dose. Praziquantel dosing at 80mg/kg resulted in higher drug exposure than at 40mg/kg. Further PK/PD modelling is ongoing pending trial unblinding.

5667

PHARMACOLOGIC MONITORING OF PLASMA CONCENTRATION OF PRAZIQUANTEL ON THE INTENSITY OF SCHISTOSOMA INFECTION IN A THERAPEUTIC EFFICACY MONITORING STUDY IN PERSONS TREATED FOR SCHISTOSMIASIS IN ABUJA, FEDERAL CAPITAL TERRITORY, NIGERIA

Godswill Iboma[1], Wellington Oyibo[2], Rita O. Urude[3], Obiageli J. Nebe[4], Michael N. Akpan[5]

[1]Centre for Transdisciplinary Research in Malaria and Neglected Tropical Diseases,College of Medicine of the University of Lagos, Nigeria, Lagos, Nigeria, [2]Centre for Transdisciplinary Research in Malaria and Neglected Tropical Diseases,College of Medicine of the University of Lagos, Nigeria, LAGOS, Nigeria, [3]National Schistosomiasis and Soil Transmitted Helminthiasis Elimination Programme, Neglected Tropical Diseases, Public Health Department, Federal Ministry of Health, Abuja, Nigeria, [4]National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, [5]Neglected Tropical Diseases Division, Public Health Department, Federal Ministry of Health, Abuja, Abuja, Nigeria

Treatment and control of schistosomiasis depend heavily on praziquantel (PZQ) which is administered mainly as a single dose of 40mg/kg body weight based on WHO recommendation. PZQ is the backbone of Mass Drug Administration (MDA), a strategy for the control and elimination of schistosomiasis. PZQ is well tolerated by patients and has few side effects, but there have been concerns of tolerance/resistance/treatment failure. Continuous therapeutic monitoring is critical for successful mass drug administration programme. We monitored therapeutic efficacy of praziquantel in a cohort of 65 participants from whom urine, plasma and stool samples were collected and processed by microscopy for Schistosoma haematobium (Sh) eggs detection by urine filtration technique, while Kato-Katz method was used for stool examination for the detection and quantification of of S. mansoni (Sm) using standard protocol. Of the 65 persons, 5years and above, a single dose of PZQ, using a praziquantel, given as DOT. After about 2weeks of follow up the blood samples of the

cohort were taken again. 51 of them [32males (62.7%) and 19 females (37.3%] with mean age of 14.5years were selected based on intensity of infection for detection and quantification of plasma levels of PZQ using High Profile Liquid Chromatography (HPLC). Plasma PZQ level was recorded in micrograms per milliliter (µg/ml). Of the 51, 44 were positive for eggs (infection group): 15 low infection (1-50 eggs), 22 moderate infections (50-400 eggs), and 6 heavy infection (>400 eggs). 7 had zero egg count (non-infection or control group). Mean plasma PZQ concentration for the non-infection group was 12.84 µg/ml, low infection 4.22 µg/ml, and 2.71ug/ml for moderate infection. Heavy infection (>400 parasites); no PZQ detected. In addition, mean plasma PZQ concentration was higher for S. haematobium infection (3.20 µg/ml), so was ERR as compared with S. mansoni. This study shows differential effect of PZQ for Sh and Sm, thus indicating an association between intensity of infection of schistosomiasis and plasma levels of PZQ and efficacy. It also shows that PZQ is rapidly taken up by schistosomes following its administration.

5668

THE PREVAILING INFECTION OF SCHISTOSOMA JAPONICUM AND OTHERZOONOTIC PARASITES IN BUBALINE RESERVOIR HOSTS IN THE RICEFIELD OF LAKE ECOSYSTEM: A CASE IN LAKE MAINIT THE PHILIPPINES

Joycelyn C. Jumawan[1], Leonardo A. Estano[2]

[1]Caraga State University, BUTUAN CITY, Philippines, [2]Mindanao State University Iligan Institute of Technology, Iligan City, Philippines

Bovines are important reservoir hosts of schistosomiasis, placing humans and animals in rice fields areas at risk of infection. This study reported the prevailing infection of zoonotic parasites from bovine feces in the rice fields adjacent to Lake Mainit lake scape in the Philippines. Formalin Ethyl Acetate Sedimentation (FEASD) was performed on 124 bovine fecal samples from rice fields and documented eggs and cysts from eight parasites: Schistosoma japonicum, Fasciola sp., Balantidium coli, coccidian oocyst, Ascaris sp., Strongyloides sp., and hookworm species. Among these parasites, Fasciola sp. harbored the highest infection with a 100% prevalence rate, followed by hookworms (50.94%), B. coli (32.22%), and S. japonicum (13.33%) respectively, while Strongyloides sp. (2.83%) reported lowest. The intensity of infection of Schistosoma eggs per gram (MPEG=4.19) among bovines is categorized as “light.” Bovine contamination index (BCI) calculations revealed that, on average, infected bovines in rice fields excrete 104,750 S. japonicum eggs daily. However, across all ricefield stations, bovines were heavily infested with fascioliasis with BCI at 162,700 Fasciola eggs per day. The study reports that apart from the persistent cases of schistosomiasis in the area, bovines in these rice fields are also heavily infested with fascioliasis. The study confirms the critical role of bovines as a reservoir host for continued infection of schistosomiasis, fascioliasis, and other diseases in the rice fields of Lake Mainit and requires immediate intervention to manage the spread of these diseases.

POOLED PEAKS PIPELINE (P3): AN R-BASED PROGRAM FOR POPULATION GENETIC ANALYSES IN POOLED SAMPLES

Kathleen M. Kuesters[1], Jessica M. Blanton[2], Jeffrey D. Kovach[3], Walter A. Blank[4], Jeffrey C. Long[5], Ronald E. Blanton[1]

[1]Tulane University, New Orleans, LA, United States, [2]University of California San Diego, San Diego, CA, United States, [3]Cleveland Clinic, Cleveland, OH, United States, [4]Independent Consultant, Atlanta, GA, United States, [5]University of New Mexico, Albuquerque, NM, United States

Over 1.5 billion people globally are infected with soil-transmitted helminths, and 230 million are infected with schistosomiasis. Although the primary diagnostic method is the microscopic examination of stool or urine, essential transmission dynamics can be identified using population genetics. Pooled egg samples facilitate the analysis of large parasite and infrapopulation numbers. While using microsatellite markers on pooled samples can measure genetic diversity and differentiation, few methods of batch analysis are currently available, and even fewer are available offline and for free. DNA sequencers and genetic analyzers store fragment analysis data as .fsa files that are read into licensed software requiring internet access, such as Peak Scanner. The Pooled Peak Pipeline (P3) is written in R and builds off the previously published Fragman package. P3 provides added quality control, produces reviewable tracings, formats the output to perform duplicate sample comparison, converts raw peak heights to allele frequencies, and computes population-level measures, including Nei’s GST, Jost D, principal coordinate analysis plot, and phylogenetic tree. P3 was tested using fsa files from Schistosoma haematobium lab strain samples and Schistosoma mansoni samples from infected Brazilians. The P3 results of the S. mansoni samples were compared to a previous analysis using traditional tools and therefore serve as an excellent control for the accuracy of P3. In conclusion, this analysis pipeline will provide free and offline access to genetic analysis following initial download, enhancing the capability to use pooled samples, egg or otherwise, for genetic analysis in low-resource settings. Although microsatellite markers are not a diagnostic tool, they are used in various genetic studies of infrapopulations, including studies of host-parasite coevolution, transmission dynamics, and drug resistance. A link to P3’s beta version will be provided.

RISK FACTORS FOR HIGHER-INTENSITY SCHISTOSOMA MANSONI INFECTION IN LAKE ALBERT COMMUNITIES, UGANDA: A CROSS-SECTIONAL STUDY

Dominic P. Dee[1], Germain Lam[1], Andrew Edielu[1], Victor Anguajibi[2], Emily L. Webb[3], Aidah Wamboko[4], Patrice A. Mawa[5], Jennifer F. Friedman[6], Amaya L. Bustinduy[1]

[1]Department of Clinical Research, London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]China-Uganda Friendship Hospital, Kampala, Uganda, [3]Department of Infectious Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Vector Control Division, Kampala, Uganda, [5]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [6]Rhode Island Hospital, Brown University, Providence, RI, United States

Schistosomiasis, a chronic trematode disease, is persistent in Lake Albert, western Uganda, the site of the Praziquantel in Preschoolers (PIP) trial. This cross-sectional study aimed to describe the infection and morbidity burden in household members of trial participants and identify risk factors to explain the persistent infection burden. Recruitment was by convenience sampling from four villages and data collection involved a survey, single Kato-Katz (KK) stool examination, hepatic ultrasound and household GPS measurement. Multilevel logistic regression assessed risk factors for moderate-to-heavy infection. Of 243 participants from 66 households, 66% were female and the median age was 22 years (IQR 12 - 33). Participants lived a median of 242m (IQR 178 - 384) from the shore, most (82%) visited the lake at least twice per day and 77% had unimproved sanitation. Despite local campaigns, only 37% reported taking praziquantel in the past year. Most participants (71%) were positive for Schistosoma mansoni on KK and 50% had moderate-to-heavy infection. Twenty-five (11%) participants had periportal fibrosis (image pattern C - F). In multivariable analysis, age and village were associated with moderate-to-heavy infection: adjusted odds ratio (aOR) 5.53 (95% confidence interval [CI] 1.72 - 17.76) for those aged 10 - 19 years vs. <10 years and aOR 0.11 (95% CI 0.03 - 0.46) for the lowest- vs. highest-burden village. There was weak evidence for a negative association with recent treatment and no association with distance to the lake or water contact. There was evidence of household clustering of moderate-to-heavy infection (intraclass correlation coefficient = .13). Schistosome infection and disease is pervasive in lakeshore communities with poor sanitation and low treatment coverage. We found clustering in infection risk which may be targetable by control programmes. Lake proximity was unimportant at the scales studied. High-intensity infections despite recent treatment suggest rapid reinfection or treatment failure. There is an urgent need for more intensive preventive chemotherapy and improved water and sanitation in endemic areas.

5671

SNAIL-SCHISTOSOME DYNAMICS IN COMPLEX ECOLOGICAL COMMUNITIES

Kelsey E. Shaw[1], Ella Arms[1], Teckla Angelo[2], Moses Mahalila[2], Raeyan Syed[1], Safari Kinung'hi[2], David Civitello[1]

[1]Emory University, Atlanta, GA, United States, [2]National Institute of Medical Research, Mwanza, Tanzania, United Republic of

Schistosomes are transmitted between human and snail hosts via free-living stages in freshwater. Historically, biocontrol of host snail species using predators and competitors has been attempted with mixed success. In this study we investigated the interactions between the ecological community and snail-schistosome dynamics in two settings. We first conducted a mesocosm experiment to investigate the impact of competition by non-host genera Melanoides and Physa on the population dynamics and schistosome transmission in Biomphalaria, host of Schistosoma mansoni. We tracked snail abundance, body size, reproduction, resources, and schistosome production for 16 weeks. Melanoides decreased the abundance of Biomphalaria and algae, suggesting strong resource competition. Physa also reduced Biomphalaria abundance. However, they increased algae and Biomphalaria body size, cercarial production, and reproduction – effects inconsistent with resource competition, but consistent with intraguild predation. Lab experiments confirmed that Physa is a voracious predator of Biomphalaria eggs. Given these strong effects of competition and predation, we surveyed non-host snail competitors and predators of in 57 waterbodies surrounding Mwanza, Tanzania, at 3 time points over the schistosome transmission season. We found significant variation in predator community composition and that community composition impacted host snail size and infection status: waterbodies with a greater abundance of notonectids and Corixidae had larger snails and a greater infection prevalence. We speculate that these smaller predators are limited to consuming small snails, thereby contributing to larger snail size and infection prevalence. Collectively, our work demonstrates that non-host species in the ecological community of host snails may have a great impact on schistosome transmission dynamics. Synthesizing these community-level processes and understanding which traits of predators and competitors matter can yield important insights into schistosome biocontrol.

5672

A COMPLEX INTERPLAY BETWEEN FOOD, HEALTH AND LIVELIHOODS - LIVE FLUKE (OPISTHORCHIS VIVERRINI) IN NORTHEAST THAILAND

Hannah C. Bialic[1], Thomas Crellen[1], Arporn Wangwiwatsin[2], Watcharin Loilome[2]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Khon Kaen University, Khon Kaen, Thailand

Transmission of the human-infective and carcinogenic trematode Opisthorchis viverrini (OV), a parasite acquired from eating raw or undercooked fish that causes cancer of the bile duct, is ongoing in Southeast Asia. The resulting cancer mainly afflicts individuals aged 40+ and once progressed is rapidly fatal with limited treatment options. Despite decades of control, this cholangiocarcinoma caused by OV remains one of the leading causes of death in Thailand and Laos and incidence rates in Northeast Thailand remain the highest in the world. Determining which interventions will be most effective requires an understanding of fundamental epidemiological processes, many of which are poorly understood. The communities most heavily affected by the parasite are lower-income rural households around the Mekong River and its tributaries where the main sources of employment are fishing, rice farming and fish farming. There is therefore a close connection between people's livelihoods and infection. Persistent public health campaigns have stigmatised the practise of eating raw fish, which has contributed to a disconnect between reported behaviour and actual eating habits. To better understand this disconnect and the complex interplay between diet, health and livelihoods from the community perspective, a food festival at a well-established food market was conducted in the highly endemic region of Maha Sarakham. Questionnaires, discussion groups and interactive activities, all conducted in the Thai language by staff and students from Khon Kaen University, formed the basis of the comprehensive qualitative and qualitative data collection from this event. This event engaged with previously overlooked community members – such as fisherman and non-risk-group individuals. Novel evidence and metrics were gathered from this festival that will be used to inform intervention methods, surveillance, treatment, and health policy. This project will also be used as a template for community engagement and epidemiological data collection and has informed research and public health policy for the region.

5673

THE SNAIL-TREMATODE-MICROBIOME TRIPARTITE INTERACTION: FROM LAB MANIPULATIONS TO THE FIELD

Ruben Schols[1], Cyril Hammoud[1], Tim Maes[2], Bruno Senghor[3], Tine Huyse[1], Ellen Decaestecker[4]

[1]The Royal Museum for Central Africa, Tervuren, Belgium, [2]The Katholic University of Leuven, Leuven, Belgium, [3]Ucad-IRD de Hann, Dakar, Senegal, [4]The Katholic University of Leuven, campus Kortrijk, Kortrijk, Belgium

Snail-borne diseases affect over 250 million people worldwide and pose a substantial burden on the livestock industry. A fundamental understanding of the drivers of the epidemiology of these diseases is crucial for the development of sustainable control measures. The microbiome is increasingly being recognized as an important player in the interaction between parasitic flatworms and snail intermediate hosts. In order to better understand this interaction, field and lab-based studies, including microbiome transplant experiments whereby the microbiome is transferred between a donor and a recipient host, are needed. We conducted a transplant and an infection experiment in the lab on Biomphalaria glabrata and collected field data in the Senegal River Basin (SRB) focused on Bulinus spp. First, a multiplex PCR was used to detect flatworm infections in snails. Next, an amplicon sequencing workflow was used to genotype up to 25 infected snails per species per site and their infecting flatworms. Finally, the microbiome of the selected snail specimens was profiled through 16S metabarcoding. We conducted a successful snail microbiome transplant and show that the phylogenetic relatedness between the recipient and donor snail affects the recipient's survival probability. Furthermore, the microbiome changes throughout flatworm infection development in B. glabrata. Moreover, sympatric host-parasite combinations might affect the microbiome differently compared to allopatric ones. Finally, the SRB field dataset showed marked variation in the microbiome between species and across regions but not between infected and uninfected samples. Combined with information on the co-infection status of our samples, these findings could provide further insights into the relationship between infection status and microbiome. Transplant experiments, complemented by field-based studies, could facilitate future research endeavors to investigate the role of specific bacteria or bacterial communities in parasitic flatworm resistance of freshwater snails and might ultimately pave the way for microbiome-mediated control of snail-borne diseases.

USING MATHEMATICAL MODELS TO UNDERSTAND SCHISTOSOMIASIS TRANSMISSION IN A UGANDAN HOTSPOT

Gregory C. Milne[1], Rebecca Oettle[2], Joanne P. Webster[1], Martin Walker[1], Shona Wilson[2]

[1]Royal Veterinary College, Brookmans Park, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom

Schistosomiasis is a neglected tropical disease of profound medical importance, infecting approximately 240 million people, 90% living in Sub-Saharan Africa. Severe schistosomiasis is associated with periportal fibrosis and portal hypertension which can cause death without appropriate disease management. A cornerstone of international efforts to eliminate schistosomiasis as a public health problem is mass drug administration

(MDA) with praziquantel. However, despite nearly two decades of MDA, the prevalence of infection and the incidence of periportal fibrosis remains high in communities along the shore of Lake Albert in Uganda, representing a conspicuous failure of the current intervention strategy. The FibroScHot Consortium is addressing this urgent public health need by conducting a randomised controlled trial to evaluate the effectiveness of delivering MDA at frequencies of up to four times per year. Reporting on research conducted as part of the Consortium, this talk presents progress from mathematical model-based analyses of the historical impact of MDA on the infection and morbidity dynamics of Schistosoma mansoni along the shore of Late Albert and discusses how severe schistosomiasis may be tackled in transmission hotspots.

MALE GENITAL SCHISTOSOMIASIS AMONG LOCAL FISHERMEN ALONG SOUTH SHORELINE OF LAKE MALAWI IN MANGOCHI DISTRICT

Sekeleghe Amos Kayuni[1], Mohammad H. Alharbi[2], Adam Abdullahi[3], Peter Makaula[1], Fanuel Lampiao[4], Janelisa Musaya[1], E. James LaCourse[2], Jaco J. Verweij[5], Johnstone J. Kumwenda[4], Peter D.C. Leutscher[6], Anna Maria Geretti[7], J. Russell Stothard[2]

[1]Malawi Liverpool Wellcome Programme (MLW), Blantyre, Malawi, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Cambridge Institute of Therapeutic Immunology & Infectious Diseases, University of Cambridge, Cambridge, United Kingdom, [4]Kamuzu University of Health Sciences, Blantyre, Malawi, [5]Laboratory for Medical Microbiology and Immunology, Laboratory for Clinical Pathology, ElisabethTweesteden Hospital, Tilburg, Netherlands, [6]Regions hospital Nordjylland, Center for Klinisk Forskning, Klinisk Institut, Aalborg Universitet, Aalborg, Denmark, [7]Department of Infectious Diseases, Fondazione PTV, University of Rome, Rome, Italy

Male genital schistosomiasis (MGS) is an ignored consequence of urogenital schistosomiasis (UGS) with schistosome eggs and pathologies in genitalia. First reported by Madden in 1911, its epidemiology, diagnostic testing and management are not well described owing to limited research and diminishing focus. Furthermore, expansion of Human immunodeficiency virus (HIV) epidemic across sub-Saharan Africa has renewed interest in MGS owing to their plausible but under-explored interactions. A longitudinal cohort study was set up among fishermen along southern Lake Malawi shoreline in Mangochi district to investigate prevalence and morbidity of MGS. Fishermen aged 18+ years were recruited and administered questionnaires, assessing knowledge, attitudes and practices associated with MGS. They submitted urine and semen for parasitological and molecular diagnostic tests: dipstick, point-of-care circulating cathodic antigen (POC-CCA), filtration, microscopy and real-time PCR. Abdominopelvic and scrotal ultrasonography were conducted for abnormalities in prostate, seminal vesicles, epididymis, testes and other organs. Standard Praziquantel (PZQ) treatment (40mg/kg) was offered to all and follow-up was done at 1, 3, 6 and 12 months. 376 fishermen (median age: 30 years, range: 18-70) were recruited and interviewed. Below 10% reported experiencing MGS symptoms, like genital or coital pain. Baseline MGS prevalence by semen microscopy was 10.4% (n=114, median: 5.0/ml) while real-time PCR was 26.6% (n=64). UGS prevalence was 17.1% (n=210, median: 2.3/10 ml). None of MGS positive participants experienced MGS symptoms. 130 fishermen had ultrasonography and 9 (6.9%) had abnormalities, 1 with prostatic nodule and another a testicular nodule. Subsequent analyses on follow-up indicated variable detection dynamics, with fewer abnormalities observed. MGS is prevalent among local fishermen along southern Lake Malawi, which calls for improved availability and accessibility to advanced diagnostics, PZQ treatment and control interventions to reduce prevalence and better manage MGS.

5676

PREVALENCE OF SCHISTOSOMIASIS AND IMPLEMENTATION OF SCHISTOSOMA PREVENTION PROJECT IN GEZIRA STATE, SUDAN 2022-23

Mazin Mohammed Osman

King Fahad Hospital, Al baha, Saudi Arabia

In several developing countries, including Sudan, schistosomiasis remains a public health problem particularly in Gezira state. The needs of clear prevalence and testing an effective environmental and social impact methods were essential to eradicate schistosomiasis .This study is composed of two major sections first to measure the prevalence of schistosomiasis in Gezira state -the second part is to implement environmental-social based interventional projects to cover an area of the gap in knowledge and attitude in one of the most prevalent villages after the primary survey result and the total study period was 18 months. The first part of study was done by Descriptive Prevalence Study design [DPS]using a case-counting survey in major health centers in Gezira state .the second part composed of three phases :-pre intervention knowledge and attitude survey . -intervention through health education session .-Post-intervention evaluation survey.The primary survey reveals S.haematobium was found in 32%, while S.mansoni infection was found in 43% of the Gezira state population, and 13% of the total number of cases in Gezira state from Alhafayer village out of hundreds of villages, that's why we choose Alhafayer village for the interventional project, the outcome of 14 months of interventions: The morbidity rate in alhafayer village has dropped from 82% to 24%. Raising awareness among the village population from 13% to 78% after assessing attitudes and practice of schistosoma-preventing methods. Opening spared section in Alhafayer heath center for diagnosis, provide treatment , and scheduling regular health education sessions for all social classes .The need for clean water sources was discussed with the Gezira government and charities .however the clean water project will start soon to cover Alhafayer and two neighboring villages .Collaboration across sectors for water supply, environmental management, and health education an intersectoral approach needed to eradicate Schistosoma. Also an Operational research is essential to develop intervention methods, diagnostic procedures, and human behavior facilitation.

5677

EVALUATION OF THE BURDEN AND RISK FACTORS ASSOCIATED WITH FEMALE GENITAL SCHISTOSOMIASIS IN TWO ENDEMIC AREAS IN MALAWI AS PART OF THE MORBIDITY OPERATIONAL RESEARCH FOR BILHARZIASIS IMPLEMENTATION DECISIONS (MORBID) STUDY

Olimpia Lamberti[1], Sekeleghe Kayuni[2], Dingase Kumwenda[2], Varsha Singh[3], Veena Moktali[3], Neerav Dhanani[4], Els Wessels[5], Lisette Van Lieshout[3], Fiona M. Fleming[4], Themba Mzilahowa[2], Amaya Bustinduy[1]

[1]Department of Clinical Research, London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Centre for Health, Agriculture and Development Research and Consulting (CHAD), Blantyre, Malawi, [3]Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands, [4]Unlimit Health, London, United Kingdom, [5]Department of Medical Microbiology, Leiden University Medical Center, Leiden, Netherlands

Female genital schistosomiasis (FGS), caused by Schistosoma haematobium (Sh) is prevalent in Sub-Saharan Africa (SSA). FGS is associated with sexual and reproductive life morbidity, and increased HIV and cervical precancer prevalence. There are no control programmes for FGS screening and diagnosis in endemic countries, hindering precise disease burden estimation. This study evaluated the burden of FGS by visual and molecular diagnostic methods in two districts in Southern Malawi. Women aged 15-65 years, sexually active, not currently menstruating, or pregnant, were enrolled from the larger MORBID study. A midwife completed a symptoms questionnaire, obtained a cervicovaginal swab and cervicovaginal lavage (CVL), and assessed FGS-associated

genital lesions using hand-held colposcopy. Visual-FGS was defined as the presence of sandy patches, rubbery papules, or abnormal blood vessels. Molecular-FGS was defined as Sh DNA detected by real-time PCR from a cervicovaginal swab. Egg-patent Sh infection was detected by urine microscopy. 950 women completed the questionnaire (median age 27, [IQR] 20-38). Visual and molecular FGS prevalence was 26.9% (260/967) and 8.2% (78/942), respectively. Of the 584 women with available genital and urinary samples, 6.5% (38/584) had egg-patent Sh infection. Multivariable logistic regression showed a positive significant association between molecular and visual FGS (OR=2.9, p<0.01). Self-reported urinary, genital, sexual and reproductive health symptoms were not predictive of FGS (p>0.05). Molecular-FGS was associated with egg-patent Sh infection (OR=7.5, p<0.01). There was no significant correlation between visual-FGS and Sh infection status (p = 0.5). Some villages had high prevalence of molecular-FGS, even with <10% prevalence of urinary Sh in school-aged children (SAC), a common treatment threshold. No significant association between visual-FGS and village Sh prevalence was found (p=0.2). This study highlights the significant burden of FGS in Southern Malawi and importance of using field-deployable screening methods for FGS diagnosis in SSA countries and determining treatment need.

5678

PRESENCE OF SARS-COV-2 RNA IN DIFFERENT SOURCES OF WATER OF NEPAL

Sarmila Tandukar[1], Eiji Haramoto[1], Samendra Sherchan[2]

[1]Interdisciplinary Center for River Basin Environment, University of Yamanashi, Kofu, Japan, [2]Morgan State University, Baltimore, MD, United States

Wastewater-based epidemiology (WBE) has been one of the most promising surveillance tools for monitoring the status, trend of infection, possible future outbreaks of coronavirus disease-2019 (COVID-19), to gather the information on disease surveillance, epidemiological models, genetic diversity, and geographic distribution. This study reports the presence and reduction of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) at two wastewater treatment plants (WWTPs) of Nepal, along with river water, hospital wastewater (HWW), and wastewater from sewer lines collected between July 2020 and February 2021. SARS-CoV-2 RNA was detected in 50%, 54%, 100%, and 100% of water samples from WWTPs, river hospitals, and sewer lines, respectively, by at least one of four quantitative PCR assays tested (CDC-N1, CDC-N2, NIID_2019-nCOV_N, and N_Sarbeco). The CDC-N2 assay detected SARS-CoV-2 RNA in the highest number of raw influent samples of both WWTPs. The highest concentration was observed for an influent sample of WWTP A (5.5 ± 1.0 log10 genome copies/L) by the N_Sarbeco assay. SARS-CoV-2 was detected in 47% (16/34) of the total treated effluents of WWTPs, indicating that biological treatments installed at the tested WWTPs are not enough to eliminate SARS-CoV-2 RNA. One influent sample was positive for N501Y mutation using the mutation-specific qPCR, highlighting a need for further typing of water samples to detect Variants of Concern. Furthermore, crAssphage-normalized SARS-CoV-2 RNA concentrations in raw wastewater did not show any significant association with the number of new coronavirus disease 2019 (COVID-19) cases in the whole district where the WWTPs were located, suggesting a need for further studies focusing on suitability of viral as well as biochemical markers as a population normalizing factor. Detection of SARS-CoV-2 RNA before, after, and during the peaking in number of COVID-19 cases suggests that WBE is a useful tool for COVID-19 case estimation in developing countries.

5679

POOR OUTDOOR BATHROOMS DRAINAGE SYSTEMS OF CHING'AMBO RESIDENTS IN MZUZU CITY AS A SAFE HAVEN AND TOOL FOR INCREASED EXPOSURE TO TROPICAL PARASITES

Vita Mithi[1], Sarah Eliza Dunn[2]

[1]Center for Life Toxicology Data, Mzuzu, Malawi, [2]Bayer/Crop Science Division, Chesterfield,, MO, United States

Bathroom drainage wastewater is a major source of water borne diseases and injuries especially in densely populated communities with a higher water table. However, water sanitation remains one of the neglected areas of research and health promotion in the fight against diseases of poverty. For this project, we aimed at investigating the implications of poor drainage systems of traditional bathrooms among residence of Ching'ambo, in Mzuzu city. We conducted an exploratory survey using quantitative and qualitative data collection methods which included photography of out-door bathrooms drainage systems, observation checklists, and in-depth interview questionnaires. A total of 60 households with traditional bathrooms were identified through random sampling technique and calculated using n=N/1+N (e)2 with 95% confidence interval participated in the study. SPSS version 16 statistical software was used for the generation of descriptive analysis. The results demonstrated that inhabitants were highly exposed to vectors or parasites that transmit neglected tropical diseases of poverty such as mosquitoes, worms, ticks, snails and other insects of medical entomology. In the study, 60% of participants reported to be victims of snakebite and physical injury while 70% perceived themselves as having experienced zoonotic diseases due to close contact with stray dogs that habited these bathrooms as safe havens. The research showed that poor and inadequate spacing for construction of out-door bathrooms wastewater pathways were important contributors for poor drainage systems which were in agreement with the reports of 68% of households respondents. Consequently, the findings of this study provide an impetus for further wastewater epidemiology and related research. Additionally, there is need for intense interventions tailored towards promotion of proper wastewater disposal leadership among residents of Ching'ambo and surrounding semi-urban communities in Mzuzu city.

5680

SOCIOCULTURAL INFLUENCES ON ACCEPTANCE AND HEALTH RISK OF WATER RESOURCES IN REMOTE COMMUNITIES IN GHANA

Forgive A. Norvivor

University of Health and Allied Sciences, Ho, Ghana

Access to clean water has an important role to play in ensuring good public health and to reduce health risks, so there are clear guidelines and pollution limits to safeguard the health of populations. Water should be free of microbial inputs, chemical inputs (heavy metals), with water quality indices values between 70 and 100. With these requirements met, consumers can accept and utilize water; however, water may be utilized for other reasons. The relationship between rural people and their environment, vis à vis water resources is deeply rooted in socio-cultural values and norms; this can influence utilization and acceptance regardless of vital health risks, but this gap has not been researched particularly in rural, remote communities. Additionally, water quality assessments usually end at comparing concentrations with WHO guideline values, however, this study assessed health risk. Key Informant Interviews were conducted among twelve purposively sampled community leaders, using an interview guide and results analyzed using Interpretative phenomenological analysis method and health risk of heavy metals were also assessed using USEPA models. Cultural norms and History influenced acceptance, utilization and protection of the water resource. Management of water resources is shrouded in Taboos and Beliefs, with little scientific underpinning; meanwhile water quality is compromised by run-off from riparian agricultural activities and some heavy metals potentially having long term effects despite recording

low concentrations. Therefore, water and policy managers need to conduct proper community engagement, to reduce any sociocultural barriers and assess health risks, in water protection interventions.

5681

MOLECULAR DETECTION OF PATHOGENIC LEPTOSPIRA AND HELICOBACTER PYLORI IN ENVIRONMENTAL SPECIMENS COLLECTED FROM THE OPISTHORCHIASIS ENDEMIC AREAS AT KHON KAEN PROVINCE, THAILAND

Shih Keng Loong[1], Manop Sripa[2], Sangduan Wannachart[2], Laksika Phumipheng[2], Thanagorn Saykaew[2], Yuchen Liu[3], Sirikachorn Tangkawattana[2], Banchob Sripa[2]

[1]Universiti Malaya, Kuala Lumpur, Malaysia, [2]Khon Kaen University, Khon Kaen, Thailand, [3]University of Liverpool, Liverpool, United Kingdom

Opisthorchiasis is a foodborne trematodiasis common in Thailand. Interestingly, opisthorchiasis endemic areas were found to have substantial incidences of leptospirosis as well as Helicobacter pylori infection. The parasite causing opisthorchiasis (Opisthorchis viverrini) has a complex life cycle involving different intermediate hosts before maturing into the infective metacercariae stage and infecting humans through ingestion of mainly raw fish. O. viverrini infection is the main risk factor for cholangiocarcinoma in humans. Since O. viverrini, Leptospira spp. and H. pylori are present in various aquatic environments, we attempted to elucidate the relationships of these pathogens at the opisthorchiasis endemic areas around the Lawa Lake region at Khon Kaen Province, Thailand. Specimens were collected from ten study sites around the Lawa Lake region at Khon Kaen Province. Mud, water, snail and fish mucus were collected from the study sites. One metacercariae specimen was also included in the study. DNA extracted from the specimens were subjected to PCR assays targeting the LipL32 (pathogenic Leptospira) and cagA (H. pylori) genes. PCR positive products were sequenced and compared using the BLAST database for identification. Sequencing of the PCR positive products revealed that the mud, fish mucus and metacercariae specimens were positive for the presence of H. pylori. Remarkably, the same mud specimens that were positive for H. pylori were also positive for the presence of pathogenic Leptospira, suggesting co-localization of these two pathogens at the same site. Our findings suggest that H. pylori and pathogenic Leptospira are prevalent in opisthorchiasis endemic areas at Khon Kaen Province, Thailand.

5682

ASSESSMENT OF THE MICROBIAL CONTAMINATION OF DELIVERY BOXES OF ONLINE FOOD DELIVERY SERVICES PROVIDERS IN ACCRA

Doreen Dedo Adi[1], Chris Y. Asare[2]

[1]Akenten Appiah-Menka University of Skills Training and Entrepreneurial Development, Kumasi, Ghana, [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

The sanitary conditions under which the food is transported is vital for safety. This study aimed at enumerating and identifying microbial contaminants of delivery boxes of food delivery service providers in Accra as an indicator of microbial quality and hygiene. Swab samples were randomly obtained from forty (40) food delivery operators at the beginning and end of week. The Total Aerobic, Total Coliform Enterobacteriaceae, Fecal Coliform, yeast and mold counts, were determined as an index of microbial quality and safety. Pathogens from the delivery boxes were isolated, characterized and identified. There was significant level of bacterial and fungal contamination in the delivery boxes. The maximum Total Aerobic count, coliforms, E. coli yeast and mold in the delivery box were 1.03×106cfu/cm2, 1.7×105cfu/cm2, 4.92×103cfu/cm2, 6.57×102 and 5.60×102 respectively at the beginning of the working week. These increased to 9.56×106cfu/cm2, 2.18×106cfu/cm2, 3.51×104 cfu/cm2, 7.61×103 cfu/cm2 and 8.31×102 cfu/cm2, respectively at the close of the week. Bacillus sp., Staphylococcus sp., Acinetobacter and Pseudomonas stutzeri. Saccharomyces cerevisiae, Rhodotorula rubra, Aspergillus niger and Penicillium sp. were isolated from the delivery boxes. The high contamination levels recorded in this study indicates the poor hygienic state and practices of the food delivery service operators in Accra. Foods and other items being transported for delivery in these boxes have a potential and risk of contamination from these pathogens and contagions, posing a public health threat to recipients and unsuspecting customers who patronize food delivery services in the highly urbanized population of Accra. Hygiene training of food delivery service providers is an urgent necessity.

INCREASING THE ACCESSIBILITY AND HANDWASHING PRACTICES THROUGH TIPPY TAPS IN CABO DELGADO PROVINCE, MOZAMBIQUE

Xavier Badia-Rius[1], James Mungai Waringa[2], Nelson Sequião[2], Maria Sacchetti[2], Anastácia Lidimba[3], Pablo Ignacio Eulogio de Sancha[2], Sérgio Lopes[1], Mussa M. Aly[4]

[1]The MENTOR Initiative, Haywards Heath, United Kingdom, [2]The MENTOR Initiative, Pemba, Mozambique, [3]Serviço Provincial de Saúde, Pemba, Mozambique, [4]Núcleo de Investigação Operacional de Pemba, Pemba, Mozambique

Diarrheal diseases including cholera are responsible for a high mortality and morbidity in humanitarian emergencies due to overcrowding, malnutrition, lack of healthcare access, water and sanitation facilities as well as handwashing stations. The province of Cabo Delgado, Mozambique, has been immersed in a severe humanitarian crisis due to conflict and insecurity since 2017. Hygiene promotion campaigns have been implemented since August 2022 including construction of a simple and low-demanding resource handwashing station, named tippy tap, in Internal Displaced Persons (IDPs) sites and host communities. The aim of this study was to describe the accessibility, use and community ownership of tippy taps. A cross-sectional survey was conducted in 5 districts after 6 months of a hygiene promotion campaign implementation. A total of 409 people participated in the survey. Overall, 63% of participants were females, the largest age group were people between 26 and 35 years old (26%) and 64% of households had at least a person with the primary education level. Thirty-one per cent of households reported to have a tippy tap within 500 meters and 22% of participants reported to use a tippy tap within the last 24 hours. A hundred and fifty-one households (37%) reported at least one case of diarrhea or stomachal pain within the previous month. The use of tippy taps was strongly associated with their accessibility ($P<0.001$) and knowledge of causes of diarrhea ($P=0.006$). Moderately evidence was found between use of tippy taps and self-reported diarrheal cases within the household during the previous month ($P=0.04$). Further construction of 1550 tippy taps in program targeted areas without programmatic support showed the strong uptake of communities demonstrating the sustainability and ownership of tippy taps as a tool to improve hygiene practices. The provision of functional and feasible handwashing stations in humanitarian contexts is crucial to increase handwashing practices for cholera and diarrheal disease prevention.

5684

WORK RELATED INJURIES: WHAT FACTORS DETERMINE ITS SEVERITY IN A LOW RESOURCE SETTING?

Regina Adiyah[1], Alfred Kwame Owusu[2], Francis Adjei Osei[1], Alexis Buunaaim[3]

[1]Centre for Research, Innovation and Development, Accra, Ghana, [2]Komfo Anokye Teaching Hospital, Accra, Ghana, [3]Tamale Teaching Hospital, Accra, Ghana

It is estimated that more than 2.3 million people (both males and females) die from work-related injury or disease; this links to over 6000 deaths daily globally. This study assessed factors influencing the severity of workplace injuries reported to Teaching Hospitals in Ghana. fr The study employed a cross-sectional prevalence survey with a quantitative approach. A simple random sampling method was used to select the study respondents. Data were captured using REDCAP and was exported from REDCap directly into Stata 16 statistical software for analysis. The total number of respondents

involved in this study was 523. Statistical significance for all testing was set as 0.05.ResultsA total of 523 workplace injuries data were extracted at the various teaching hospitals, less than half the number of injured patients (38.43%) were admitted at KATH. The respondents who resided in rural areas were 2.60 more likely to experience severe workplace injuries (AOR=2.60, 95% CI=1.19-5.69). Exposure to burns, blunt and penetrating injuries increased the likelihood of experiencing severe workplace injuries (AOR=20.46; 95% CI=2.25-186.06), (AOR=19.39; 95% CI=2.14-175-27) and (AOR=9.33; 95% CI=1.53-56.99) respectively. ConclusionThe sentinel hospital site, type of settlement, and mechanism of injury were established to be influencing the severity of workplace injuries. The authors recommend the prioritization of stakeholder involvement such a as industry management team to work towards practical steps to address this burden education

5685

ASSOCIATION OF PRENATAL ENVIRONMENT FACTORS WITH UNDER FIVE NUTRITIONAL GROWTH OUTCOMES IN UGANDA

Paddy Ssentongo[1], Claudio Fronterre[2], Steven Schiff[3]

[1]Penn State Hershey Medical Center, Hershey, PA, United States, [2]Lancaster University, Lancaster, United Kingdom, [3]Yale University School of Medicine,, New Haven, CT, United States

Children with nutritional growth failure are more susceptible to infections and may experience cognitive, physical, and metabolic developmental impairments. Many countries in Africa depend on rain-fed agriculture for food security which is reflected in meteorological environment factors. The objective of the current study is to assess meteorological factors associated with village-level rates of child nutritional growth outcomes in Uganda. This was a cross-sectional study of 5219 children ages 0 to 59 months with anthropometric measures using the 2016 Ugandan Demographic and Health Survey. Geostatistical models parameterized by meteorological, land topography and sociodemographic factors were developed to determine their association with height-for age z-scores (HAZ), weight-for-age z-scores (WAZ), and weight-for-height z-scores (WHZ). Of the 5219 children ages 0 to 59 months included in the analysis, 50% were male, and mean age was 33 (SD:16) months. Large disparities in the burden of child growth failure exist within Uganda at smaller and larger spatial scales; villages in the northeastern and southeastern areas of the country bear the highest prevalence of all forms of child undernutrition. Higher SPEI 3 months pre-birth was positively associated with child nutritional growth outcomes. Additionally, higher location mean rainfall 11 months pre-birth was positively associated with HAZ consistent with SPEI findings. Aridity index association with WAZ and WHZ were consistent with findings of SPEI. Slope angle, land surface mean temperature, travel time to the nearest city, and nighttime light emissions were not consistent with nutritional growth outcomes. In conclusion, pre-birth availability of agricultural water was associated with nutritional child growth outcomes.

BARRIERS OF EFFECTIVE AND SUSTAINABLE WATER, SANITATION AND HYGIENE (WASH) SERVICES AT SCHOOLS IN BANGLADESH

Debashish Biswas[1], Md. Rofi Uddin[1], Jyoti Bhushan Das[1], Md. Asadullah[1], Mahbub-Ul Alam[1], Habibur Rahman[2], Pritum Kumar Saha[2], Emanuel Owako[3], Mahbubur Rahman[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Water & Sanitation for the Urban Poor (WSUP), Dhaka, Bangladesh, [3]Water & Sanitation for the Urban Poor (WSUP), London, United Kingdom

Considering the potential effect of a poor environment in schools on children, every school requires appropriate WASH initiatives that include provision of WASH facilities and sustainable operation and maintenance (O&M) of those facilities. In Bangladesh, all government schools are mandated to have a School Management Committee (SMC) who are responsible for ensuring WASH O&M. However, in majority of the schools SMCs didn't perform better in sustainably operating and maintaining their WASH infrastructure. We investigated the barriers for successful O&M of WASH services in schools to help inform strategies. We conducted qualitative interviews with 36 SMC members from purposively selected 18 primary schools in three cities in Bangladesh between Feb- Apr 2020. All interviews were audio recorded, transcribed verbatim and we performed thematic content analysis. The major problem identified was economic. Due to low funding from government, lack of private contributions and lack of financial mechanism, SMCs were unable to make investment decision to ensure supplies as well as recruiting a janitor. Inadequate supplies of cleaning products, handwashing agents left toilets unclean and allow students to wash their hands with water only. Moreover, if maintenance is required when facilities were broken or blocked and need the septic tanks emptied, or replacement of tube wells, SMCs were unable to do it as they did not have their own fund. Children were not aware of how to use the facilities properly, and did not have good hygiene practices. Community contribution was poor in terms of proving good hygiene practices to children and in improving WASH facilities at schools. Communication and coordination gaps between SMCs and other stakeholders were also an important barrier. Moreover, there was an institutional lack of planning and adoption of WASH policies or they lack the capacity, time, and resources for appropriate decision making and planning of WASH services for their schools. Providing information and train SMC for capacity building, establishing a strong financial mechanism may be useful for successful O&M of school WASH in a sustainable way.

EVALUATION OF A MULTI-LEVEL, PARTICIPATORY INTERVENTION TO REDUCE ARSENIC EXPOSURE IN AMERICAN INDIAN COMMUNITIES: A CLUSTER RANDOMIZED CONTROLLED TRIAL OF THE COMMUNITY-LED STRONG HEART WATER STUDY PROGRAM

Christine Marie George[1], Tracy Zacher[2], Kelly Endres[1], Francine Richards[2], Lisa Bear Robe[2], David Harvey[3], Lyle G. Best[2], Reno Red Cloud[4], Annabelle Black Bear[5], Steve Ristau[6], Dean Aurand[6], Leslie Skinner[5], Christa Cuny[7], Marie Gross[7], Elizabeth D. Thomas[1], Ana Rule[1], Kellogg Schwab[1], Lawrence H. Moulton[1], Marcia O'Leary[5], Ana Navas-Acien[8]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Missouri Breaks Industries Research Inc., Eagle Butte, SD, United States, [3]Indian Health Service, Rockville, MD, United States, [4]Environmental Resource Department, Oglala Sioux Tribe, Rapid City, SD, United States, [5]Missouri Breaks Industries Research, Inc, Eagle Butte, SD, United States, [6]Mid Continent Testing Labs, Inc, Rapid City, SD, United States, [7]Missouri Breaks Industries Research, Inc, Eagle Butte, SD, United States, [8]Columbia University Mailman School of Public Health, New York, NY, United States

Chronic arsenic exposure has been associated with an increased risk of cardiovascular disease, diabetes, cancers of the lung, pancreas and prostate, and all-cause mortality in American Indian communities in the Strong Heart Study. The Strong Heart Water Study (SHWS) designed and evaluated a multi-level, participatory community-led intervention to reduce arsenic exposure among private well users in partnership with Northern Great Plains American Indian Nations. A cluster randomized controlled trial (cRCT) was conducted to evaluate the effectiveness of the SHWS program over a two-year period on: (1) urinary arsenic; and (2) reported use of arsenic safe water for drinking and cooking. The cRCT compared the installation of a point-of-use arsenic filter and a mobile health (mHealth) program (3 phone calls; SHWS mHealth & filter arm) to a more intensive program, which included this same program plus 3 home visits (3 phone calls and 3 home visits; SHWS intensive arm). A 48% significant reduction in urinary arsenic (geometric mean 13.2 to 7.0 µg/g creatinine) was observed from baseline to the final 2 year follow-up when both study arms were combined (Geometric mean ratio (GMR): 0.52 (95% Confidence Interval: 0.39, 0.69)). By treatment arm, the reduction in urinary arsenic from baseline to the final follow-up visit was 57% in the mHealth & filter arm and 29% in the intensive arm. There was no significant difference in urinary arsenic levels by treatment arm at the final follow-up visit (GMR comparing the intensive vs. mHealth & filter arms: 1.21 (95% CI: 0.77, 1.90). In both

arms combined, exclusive use of arsenic-safe water from baseline to the final follow-up visit significantly increased for water used for cooking (17% to 50%) and drinking (12% to 43%). Delivery of the community-led SHWS program, including the installation of a point-of-use arsenic filter and an mHealth program on the use of arsenic-safe water without home visits, resulted in a significant reduction in urinary arsenic and significant increases in reported use of arsenic-safe water for drinking and cooking during the two-year study period.

5688

A CLUSTER RANDOMIZED CONTROLLED NON-INFERIORITY TRIAL TO COMPARE THE PROTECTIVE EFFECTIVENESS OF SULFADOXINE PYRIMETHAMINE AND AMODIAQUINE AND DIHYDROARTEMISININ PIPERAQUINE FOR SEASONAL MALARIA CHEMOPREVENTION AMONG CHILDREN 3 TO 59 MONTHS, IN THE CONTEXT OF HIGH PARASITE RESISTANCE, KARAMOJA REGION, UGANDA

Anthony Nuwa[1], Richard Kajubi[1], Craig Bonnington[2], Kevin N. Baker[2], Chuks Nnaji Nnaji[2], Musa Odongo[1], Tonny Kyagulanyi[1], Jane I. Nabakooza[3], David S. Odong[1], Denis Rubahika[3], Maureen Nakirunda[1], Godfrey Magumba[1], Madeleine Marasciulo-Rice[4], Jane Achan[2], Christian Rassi[5], Erica Viganó[2], Jennifer Ainsworth[2], Damian Rutazaana[3], Jimmy Opigo[3], James K. Tibenderana[2]

[1]Malaria Consortium, Kampala, Uganda, [2]Malaria Consortium, London, United Kingdom, [3]Ministry of Health, Uganda, Kampala, Uganda, [4]Malaria Consortium, Raleigh, NC,, NC, United States, [5]Malaria Consortium, London, Uganda

In areas with highly seasonal malaria transmission, seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine and amodiaquine (SPAQ) is recommended for age groups at high risk of severe malaria. However, due to widespread prevalence of resistance markers associated with parasite resistance to SP and AQ in east and southern regions of Africa, there was need to explore an effective alternative regimen for SMC that could be used if SPAQ starts to lose efficacy. We assessed the effectiveness of SMC for prevention of malaria among 3,853 children aged 3-59 months using a three-arm open-label prospective cluster-randomized controlled trial (cRCT) in Karamoja sub-region in Uganda. A total of 3,749 children were randomized to receive SMC with either SPAQ (1,698) or dihydroartemisinin-piperaquine (DHAPQ) (1,667) while 384 acted as control and relied on standard malaria care over the five-month high transmission period. In total, 554,155 person-days (251,414 in the SPAQ arm, 249,069 in the DHAPQ arm and 53,672 in the control arm) were generated for analysis. There were 464 events of clinical malaria (76 in the SPAQ arm, 66 in the DHAPQ arm and 322 in the control arm). These represent an incidence rate of 8 confirmed malaria events per 10,000 person-days in the entire study population (3 per 10,000 person-days in the SPAQ arm, 3 per 10,000 person-days in the DHAPQ arm and 60 per 10,000 person-days in the control arm). 750 samples were corrected one month before and after implementation of SMC and assessed for markers of resistance for SP, AQ and DHAPQ. Compared with children in the control arm, those in the SPAQ arm had a 94% lower risk of having an RDT-confirmed malaria episode; Hazard Ratio (HR): 0.06 (95% confidence interval [CI], 0.04 - 0.08, p<0.001); while those in the DHAPQ arm had a 96% lower risk; HR: 0.04 (95% CI, 0.03 - 0.06, p<0.001). The hazard ratio for the protective effectiveness of SPAQ was non-inferior to that of DHAPQ. In our setting, DHAPQ was not superior to SPAQ in terms of prevention of clinically significant malaria in SMC-eligible children.

5689

MATAMAL: A CLUSTER - RANDOMIZED PLACEBO-CONTROLLED TRIAL TO EVALUATE THE ADDITIVE IMPACT OF IVERMECTIN TO DIHYDROARTEMISININ-PIPERAQUINE SEASONAL MASS DRUG ADMINISTRATION FOR MALARIA CONTROL ON THE BIJAGOS ARCHIPELAGO OF GUINEA-BISSAU

Harry Hutchins[1], John Bradley[1], Elizabeth Pretorius[1], Eunice Teixeira da Silva[2], Hristina Vasileva[1], Robert T. Jones[1], Mamadou Ousmane Ndiath[3], Harouna dit Massire Soumare[3], David Mabey[1], Jose Ernesto Nante[4], Cesario Martins[2], James G. Logan[1], Hannah Slater[5], Chris Drakeley[1], Umberto D'Alessandro[3], Amabelia Rodrigues[2], Anna Last[1]

Ivermectin (IVM) is an anthelminthic drug that effectively kills anopheles mosquitoes which blood-feed on treated individuals. Small phase 2 and 3 clinical trials have demonstrated its potential to reduce malaria incidence, and modelling studies suggest that it could be an effective tool to reduce malaria transmission, particularly if given as Mass Drug Administration (MDA) in combination with Dihydroartemisinin-Piperaquine (DP) MDA. The safety and efficacy of IVM and DP in combination has been demonstrated previously. MATAMAL is a cluster-randomised placebo-controlled parallel assignment clinical trial conducted on the Bijagos Archipelago of Guinea-Bissau, testing whether the addition of IVM (300mcg/kg/day for 3 days) to DP MDA each month for three months during the rainy season significantly reduces malaria prevalence compared to giving DP MDA with placebo ((IVM-P), 300mcg/kg/day for 3 days). MDA was given in the context of standard malaria control measures, including insecticide-treated bed nets. MATAMAL is the largest trial to evaluate the additive impact of IVM MDA, and the only trial to evaluate combined IVM/DP MDA versus a placebo control. The trial arms consisted of 24 clusters, with 12 allocated to each of DP+IVM and DP+IVM-P, distributed monthly in July, August and September of 2021 and 2022. The primary outcome is the difference between arms in malaria prevalence, measured by estimating the cluster-adjusted prevalence of Plasmodium falciparum by varATS qPCR in a random sample of individuals of all ages during the endpoint survey, conducted during the peak transmission season. Secondary outcomes include safety and tolerability, clinical malaria incidence, entomological outcomes and the wider impact of IVM on co-endemic IVM-sensitive infectious diseases. Approximately 24,000 individuals received MDA for 2 years. The MDA was well-tolerated with relatively few adverse events that were predominantly mild in severity. 4,305 individuals were sampled in the primary outcome survey. The primary outcome and select secondary outcome data will be presented.

5690

MONITORING SUSTAINED IMPACT ONE YEAR AFTER MASS DRUG ADMINISTRATION IN A LOW-MODERATE MALARIA TRANSMISSION SETTING OF SENEGAL WITH OPTIMIZED CONTROL INTERVENTIONS

Abdoulaye Diallo[1], Ari Fogelson[2], El-hadji Ba Konko Ciré[1], Amadou Seck[1], Tidiane Gadiaga[3], Michelle E. Roh[4], Sylla Thiam[1], Seynabou Gaye[5], Ibrahima Diallo[5], Aminata Colle Lo[1], Elhadji Diouf[1], Omar Gallo Ba[1], Alioune Badara Gueye[6], Xue Wu[4], Paul Milligan[2], Erin Eckert[4], Roly Gosling[2], Adam Bennett[4], Jimee Hwang[7], Doudou Sene[5], Fatou Ba[5], Serigne Amdy Thiam[5], Bayal Cisse[3], Katharine Sturm-Ramirez[8], Jean Louis Ndiaye[1], Michelle Hsiang[4]

[1]Université Iba Der Thiam de Thiès, Thiès, Senegal, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]District of Tambacounda, Ministry of Health and Social Action, Tambacounda, Senegal, [4]US President's Malaria Initiative, Impact Malaria, Washington, DC, United States, [5]Senegal National Malaria Control Programme, Ministry of Health and Social Action, Dakar, Senegal, [6]US President's Malaria Initiative,

United States Agency for International Development, Dakar, Senegal, [7]US President's Malaria Initiative, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [8]US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dakar, Senegal

Mass drug administration (MDA) is not recommended for malaria transmission reduction in moderate transmission settings due to a lack of evidence of sustained impact. Short-term results of an open-label, cluster-randomized controlled trial in a low-moderate malaria transmission setting demonstrated MDA targeting individuals ≥3 months of age was associated with a 53% [95% CI: 29%, 69%] greater reduction in malaria incidence in all ages from baseline compared to standard-of-care which included seasonal malaria chemoprevention (SMC) given to children 3-120 months of age. Here we assessed if the impact was sustained one year after MDA. The study occurred in Tambacounda, Senegal, where district-level annual incidence was 50-200/1000 population in 2016-2019. Prior to the trial, optimized control interventions were introduced (i.e., proactive community case management and mass distribution of pyrethroid-piperonyl butoxide nets) in all 60 study villages. Villages were randomized 1:1 to receive 3 rounds of MDA with dihydroartemisinin-piperaquine+single low-dose primaquine (DP+SLD-PQ) or standard-of-care which included 3 cycles of SMC with sulfadoxine-pyrimethamine+amodiaquine; coverage was 80-84% and 93-94% of the eligible population, respectively. In 2022, the year after MDA rounds were completed, SMC was resumed in all villages. The primary outcome was malaria incidence confirmed by rapid diagnostic test by village health workers and at health facilities during the high transmission season of the post-intervention year, with subgroup analyses by MDA coverage, age (≥ vs. <10 years), and baseline malaria endemicity. Incidence rates in the MDA arm were 188 cases/1000 in 2020, 93/1000 in 2021, and 130/1000 in 2022, compared to 211, 179 and 152 cases/1000 in the control arm. The adjusted rate ratio (MDA:control) in the post-intervention year was 0.81 [95% CI: 0.51, 1.29]. While a substantial reduction in incidence was seen in the intervention year, this was not sustained in the year after MDA. Higher population coverage and/or more rounds and/or years of MDA may be needed to achieve a sustained impact. Subgroup analyses will be presented.

5691

TREATMENT OF UNCOMPLICATED MALARIA USING ARTEMISININ-BASED COMBINATION THERAPY IN THE FIRST TRIMESTER OF PREGNANCY: EXPERIENCE FROM TANZANIA

Abdallah Lusasi[1], Geofrey Makenga[2], Sijenunu Aaron[1], Samwel Lazaro[1], Frank Chacky[1], Naomi Serbantez[3], Sigsbert Mkude[2], Fabrizio Molteni[4], Chonge Kitojo[3]

[1]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [2]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [3]U.S. President's Malaria Initiative, USAID, Dar es Salaam, Tanzania, United Republic of, [4]Swiss Tropical Public Health Institute, Dar es Salaam, Tanzania, United Republic of

Artemether-lumefantrine (AL) has been the recommended first-line treatment for uncomplicated malaria and has been widely available in retail markets in Tanzania since 2006. The World Health Organization recommended AL for the treatment of uncomplicated malaria in pregnancy (MiP) in the first trimester of pregnancy in November 2022. This decision came two years after Tanzania revised its malaria treatment guidelines in 2020 recommending AL for the treatment of MiP in the first trimester. We describe the Tanzanian experience following this policy change. We reviewed data from public and private health facilities from the Health Management Information Systems (HMIS) in all 26 regions of Tanzania between January 1, 2016 and December 31, 2022. The updated treatment guidelines were disseminated throughout Tanzania to all facilities (>9,000) by December 2021. In Tanzania, all pregnant women are tested for malaria at their first antenatal care (ANC) visit. However, as midwives may not prescribe antimalarials, all women who test positive at ANC are referred to the outpatient department for treatment. The HMIS does not disaggregate malaria treatment by pregnancy status; therefore, the proportion of pregnant women who tested positive during ANC was used as a proxy indicator for MiP treatment. The proportion of pregnant women tested for malaria during ANC increased from 75% 2016 to 98% in 2022. The malaria test positivity rate ranged between 6-7% between 2016-2022. All pregnant women who tested positive regardless of trimester received AL following implementation of the 2020 treatment policy. It was noted that the HMIS did not capture whether cases were uncomplicated or severe, nor was there a way to directly report adverse drug reactions. AL stock remained >95% in both public and private facilities. Our review suggests a high level of adherence in Tanzania to the updated policy recommending AL for treatment of MiP in the first trimester.

5692

ANTI-GAMETOCYTE ACTIVITY AND POST-TREATMENT PROTECTIVE EFFICACY OF ARTEMETHER-LUMEFANTRINE VS. DIHYDROARTEMISININ-PIPERAQUINE FOR UNCOMPLICATED MALARIA: PRELIMINARY RESULTS OF A MULTI-DOSE PHARMACOKINETIC/PHARMACODYNAMIC TRIAL

Jean-Bertin B. Kabuya[1], Jay Sikalima[2], Luc Kambale Kamavu[3], Proscovia Miiye Banda[3], Amary Fall[4], Heba H. Mostafa[4], Liusheng Huang[5], Francesca Aweeka[5], Jeffrey A. Bailey[6], Jonathan J. Juliano[7], Philip E. Thuma[8], Gershom Chongwe[1], Theresa A. Shapiro[4], William J. Moss[9], Matthew M. Ippolito[4]

[1]Tropical Diseases Research Centre, Ndola, Zambia, [2]CHAZ, Lusaka, Zambia, [3]Saint Paul's General Hospital, Nchelenge, Zambia, [4]Johns Hopkins School of Medicine, Baltimore, MD, United States, [5]University of California, San Francisco, San Francisco, CA, United States, [6]Brown University, Providence, RI, United States, [7]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [8]Macha Research Trust, Macha, Zambia, [9]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Mass drug administration (MDA) for P. falciparum malaria elimination remains a controversial practice. Currently, the favored agent is dihydroartemisinin-piperaquine (DP) due to its longer half-life and its designation in Africa as second-line to artemether-lumefantrine (AL). We conducted a randomized trial of the comparative anti-gametocyte and secondary chemopreventive effects of AL vs. DP to elicit information relevant to their deployment in different contexts. Zambian children <5 years old (n=182) with uncomplicated malaria were randomized to AL or DP, admitted 72 hours for parasite and drug kinetics, and followed for 9 weeks. 173 participants (95%) contributed 1,424 person-weeks of observation time. Participants were similar at baseline across all covariates, including parasite and gametocyte density. From thin smears, asexual clearance did not differ between the groups but gametocyte clearance was more rapid and durable in the AL group. In those with baseline gametocytemia, 100% (8/8) in the AL group were clear by 1 week compared to 62% (5/8) in the DP group (p=0.04). In those with gametocytes at any time, gametocyte density was significantly lower in the AL group (AUC 38 gam.*h/mL (95% CI 13-107) vs. 136 (95% CI 34-550) in the DP group, p<0.001), the proportion with gametocytemia was significantly lower in the AL group at all weeks, and those treated with DP were significantly more likely to have emergent gametocytemia. The overall incidence of recurrent asexual parasitemia was higher in the AL vs. DP group (hazard ratio 1.9, 95% CI 1.3-2.7, p=0.001) but by 9 weeks there was no significant difference in the cumulative prevalence of recurrent parasitemia (AL 58% vs. DP 49%, p=0.31) or clinical failure (AL 19% vs. 18%, p=0.89). Molecular and chemical assays to generate high-resolution gametocyte dynamics and drug pharmacokinetics are underway, but these preliminary results support a differential impact on gametocytes that could have relevance for how these agents are deployed in different malaria contexts, pointing to a need for pairing primaquine with DP to eradicate gametocytes or prioritizing an alternative combination for MDA.

5693

PHARMACOMETRIC ASSESSMENT AND DOSE-OPTIMIZATION OF PRIMAQUINE IN THE RADICAL CURE OF PLASMODIUM VIVAX MALARIA IN CHILDREN: AN INDIVIDUAL PATIENT DATA META-ANALYSIS

Joel Tarning[1], Palang Chotsiri[1], Kanoktip Puttaraksa[1], Robert J. Commons[2], Julie A. Simpson[3], Karen I. Barnes[4], Philippe J. Guerin[5], ric N. Price[2], Paediatric Primaquine Study Group[5]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Global Health Division, Menzies School of Health Research, Charles Darwin University, Darwin, Australia, [3]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, [4]University of Cape Town, Cape Town, South Africa, [5]WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom

Primaquine is one of only two registered antimalarials for the radical cure of P. vivax malaria. The main burden of malaria is in young children and yet there is no suitable pediatric formulation. After decades of use, primaquine dosing recommendations in the pediatric population are still ambiguous. Weight-based and age-based dosing have yet to be optimized, resulting in increased variability in drug exposure and under-dosing in young children. Pharmacokinetic studies were identified through a systematic literature review of articles published in PubMed, Google Scholar, Embase, ClinicalTrials.gov, or conference proceedings between 1960 and 2021, following PRISMA guidelines. Investigators were invited to contribute individual-level patient data to the WWARN repository as part of the study group. Primaquine concentration-time data were analyzed using nonlinear mixed-effects modelling, with a particular focus on the impact of body weight and age. A total of 24 studies (15,862 measured primaquine and 10,693 carboxyprimaquine concentrations), including 2,399 adults and 226 children <5 years, were identified and included in this pooled meta-analysis. Primaquine pharmacokinetics were best described by a one-compartment distribution model, with transit absorption. Nonlinear relationships between total drug exposure and body weight and age were observed, highlighting the need for a pharmacometric approach to evaluate and design evidence-based optimal dosing in young children. The final pharmacokinetic model was used to explore different dosing scenarios with the available dose strengths of 5, 7.5, and 15 mg tablets, which demonstrated unacceptably high exposures in young children. Our findings support the development of novel pediatric formulations that can be used more accurately in this specific population. With the current tablet strengths, a tablet needs to be broken or dissolved in water to administer an appropriate dose in young children. An optimized weight-based dosing was successfully derived with current dosing strengths for patients ≥12 kg body weight, comprising five weight-bands.

FDA-APPROVED KINASE INHIBITORS AS POTENTIAL ADJUNCTIVE THERAPY CANDIDATES FOR ENDOTHELIAL DYSFUNCTION IN CEREBRAL MALARIA

Luana S. Ortolan[1], Priyanka Bansal[1], Veronica Primavera[1], Sabrina Epiphanio[2], Alexis Kaushansky[1], Joseph D. Smith[1]

[1]Seattle Children's Research Institute, Seattle, WA, United States, [2]Universidade de Sao Paulo, Sao Paulo, Brazil

Cerebral malaria is associated with cerebral coagulopathy, breakdown of the blood-brain barrier (BBB), and severe brain swelling in children, but currently there are no adjunctive drug treatments. To identify new therapeutics for inflammatory injury to blood vessels, we first screened in vitro 31 FDA-approved kinase inhibitors (KI) drugs in primary human microvascular brain endothelial cells monolayers challenged with the procoagulant protein thrombin or with Plasmodium falciparum lysates and down-selected promising candidates to evaluate in the experimental cerebral malaria model. From the in vitro screen, the BCR-ABL family of drugs showed diverse endothelial barrier phenotypes ranging from protective, neutral, to barrier disruptive. In addition, BCR-ABL drugs had anti-malaria activity with Nilotinib and Bosutinib preventing Plasmodium falciparum ring-stage parasite progression to trophozoite stage and Imatinib targeting late-stage parasites. From in vivo analysis in the ECM model, Bosutinib and Imatinib had modest protection in an early-stage treatment regimen (days 4 to 7). By comparison, Nilotinib, showed substantial protection against neuropathologic injury and lung injury measured by a rapid murine coma and behavior score, associated with BBB protection and parasitemia control. Moreover, when given as a late-stage treatment, Nilotinib on its own improved animal survival by 40% and reduced vascular leakage at the brain, lungs, and kidneys, and further increased animal survival and accelerated parasite clearance when given as an adjunctive drug with artesunate. Our work demonstrates that kinase inhibitors are an attractive drug-repurposing option to treat vascular leakage at vital organs during malaria infection and to pursue for cerebral malaria adjunctive therapy.

Leishmania braziliensis infection results in inflammation and skin injury, with highly variable and unpredictable clinical outcomes. Here, we investigated the potential impact of microbiota on infection-induced inflammatory responses and disease resolution by conducting an integrated analysis of the skin microbiome and host transcriptome on a cohort of 62 L. braziliensis-infected patients. We found that overall bacterial burden and microbiome configurations dominated with Staphylococcus spp. were associated with delayed healing and enhanced inflammatory responses, especially by IL-1 family members. Dual RNA-seq of human lesions revealed that high lesional S. aureus transcript abundance was associated with delayed healing and increased expression of IL-1β. This cytokine was critical for modulating disease outcome in L. braziliensis-infected mice colonized with S. aureus, as its neutralization reduced pathology and inflammation. These results implicate the microbiome in cutaneous leishmaniasis disease outcomes in humans and suggest host-directed therapies to mitigate the inflammatory consequences.

REPROGRAMMING EIF4A-DEPENDENT MRNA TRANSLATION TO CONTROL LEISHMANIA INFECTION

Leonardo Cortazzo da Silva[1], Camila Almeida Cardoso[1], Visnu Chaparro[1], Louis-Phillipe Leroux[1], Amin Azimin[2], Reza Salavati[2], Jerry Pelletier[2], Lauren Brown[3], John Porco[3], Maritza Jaramillo[1]

[1]INRS – Centre Armand-Frappier Santé Biotechnologie, Laval, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]Boston University, Boston, MA, United States

Protozoan parasites of the genus Leishmania are causative agents of leishmaniasis, a spectrum of tropical neglected diseases. The lack of efficient vaccines and failure to control emerging parasite resistance reflect the need to identify novel targets for therapeutic intervention. More specifically, to counteract parasite resistance, a host-directed therapy, boosting and/or modulating host responses to control the infection is desired. Our laboratory demonstrated that one third of protein-coding mRNAs in macrophages are differentially translated upon infection by Leishmania donovani. In silico analysis indicated activated translation

dependent on the mRNA helicase eIF4A upon infection. Notably, pharmacological inhibition of mammalian eIF4A reduced L. donovani and L. amazonensis survival within macrophages. Selective inhibitors of eIF4A, named rocaglates, have immunomodulatory and antimicrobial properties associated with their ability to fine-tune macrophage functions. Hence, we postulate that pharmacological inhibition of eIF4A-dependent translational programs contributes to control Leishmania infection. To begin testing this hypothesis, we assessed the leishmanicidal activity of a panel of 20 synthetic rocaglates with high affinity for mammalian eIF4A1 (i.e., strong eIF4A1 clampers). As negative controls, we included another subset of 20 rocaglates that promote either low or no clamping of eIF4A1 (i.e., weak/dead eIF4A clampers). Our screening identified four strong eIF4A1 clampers (i.e., C26, C29, C37 and C38) that reduce the infection index in bone marrow-derived macrophages (BMDMs) by more than 50% when compared to DMSO-treated control cells. Surprisingly, five eIF4A1 weak clampers (i.e., C3, C7, C11, C18 and C20) were also able to control intramacrophage Leishmania replication. Additionally, selected rocaglates showed an effect in reducing the infection index of infected THP-1 derived macrophages, validating our findings in a human model. In line with these data, the leishmanicidal activity of rocaglates with strong affinity for eIF4A1 was either partially or completely abrogated in BMDMs derived from Elf4A1+/- mice. In contrast, the anti-parasitic action of eIF4A weak clampers was resistant to reduced eIF4A1 levels in BMDMs. As expected, polysome tracing experiments revealed that only strong eIF4A1 clampers inhibit macrophage mRNA translation rates. To further elucidate the mechanism through which rocaglates act in infected macrophages, we performed a time course of infection in treated cells and identified what appears to be stalling of the parasite replication, instead of parasite killing. These stalled parasites, however, can reinfect and replicate in new, untreated BMDMs, hinting at a host-directed effect, with macrophages being the main target of rocaglate treatment. Taken together, our data allow us to conclude that strong clamper rocaglates seem to inhibit the replication of L. amazonensis in a host eIF4A-dependent manner, both in mouse and human macrophages. Weak clampers, on the other hand, are not dependent on host eIF4A1 for their anti-leishmanial effect and do not seem to be affecting the translation rate of the host cells, suggesting a yet-to-be identified translation-independent host or parasite target that is responsible for the observed effect. Currently, we are implementing a host- and parasite-based multi-omics approach to identify changes in the translatome and the proteome of intramacrophage parasites and their host cells associated with the leishmanicidal activity of strong and weak eIF4A1 clampers identified in our screening. Our long-term goal is to provide insight on the mechanistic basis and therapeutic potential of modulating eIF4A-dependent and -independent translational programs to reduce morbidity and mortality associated with visceral and cutaneous leishmaniasis.

BORRELIA BURGDORFERI CO-EXPOSURE ENHANCES IN VITRO HOST CELL SUSCEPTIBILITY TO LEISHMANIA INFANTUM AND INDUCES TH17-LIKE CELL RESPONSES IN L. INFANTUM-SEROPOSITIVE DOGS

Danielle Pessoa-Pereira[1], Breanna M. Scorza[1], Karen Cyndari[2], Erin A. Beasley[1], Christine A. Petersen[1]

[1]University of Iowa, Iowa City, IA, United States, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, United States

Canine leishmaniasis (CanL), a zoonotic disease caused by Leishmania infantum, is classically transmitted via sand flies from reservoir dogs to nearby people. Dogs with CanL are often coinfected with tick-borne bacteria, such as Borrelia burgdorferi. These co-infections were causally associated with disease progression and mortality, but specific mechanisms affecting microbicidal responses against L. infantum are unknown. We hypothesize B. burgdorferi co-infection impact host and T cell responses, prompting L. infantum replication and survival. Exposure to B. burgdorferi significantly increased L. infantum parasite burden in DH82 canine macrophage cells. Late apoptosis was significantly decreased in co-infected DH82 cells compared to uninfected and L. infantum-single infected cells. Co-infected DH82 cells showed an enhanced inflammatory response, with upregulation of TNFA, IL6, and IL1B, and concomitant release confirmed via ELISA. Ex-vivo stimulation of PBMCs from L. infantum-seropositive subclinical dogs with spirochetes and/or TLA had limited induction of IFN-γ. In L. infantum-seropositive dogs, co-exposure significantly induced expression of pro-inflammatory cytokines known to induce Th17 differentiation and effector functions, such as IL23p19, IL17A, and IL22, compared to unstimulated and TLA-single stimulated cells. Co-stimulation significantly increased the production of IL-17A and chemokines associated with neutrophilic (IL-8 and CXCL1) and monocytic (CCL2) recruitment compared to TLA-single stimulated PBMCs. L. infantum and B. burgdorferi co-infection promoted robust alterations in the host cell immune response and death, contributing to enhancing L. infantum survival and replication in DH82 cells. B. burgdorferi exposure induced pro-inflammatory and Th17-like responses in PBMCs from L. infantum-seropositive dogs. Excessive inflammation has been shown to contribute to the development of visceral leishmaniasis. Preventing tick-borne disease through already available preventatives will make a significant difference in CanL control and prevent spread of L. infantum in dogs and humans.

STAT6-DEPENDENT/IL-5-MEDIATED EOSINOPHILIA PRIMED BY PRE-EXPOSURE TO UNINFECTED SANDFLY VECTOR BITES ENHANCE SUBSEQUENT LEISHMANIA INFECTION

Chukwunonso O. Nzelu[1], Matheus B. H. Carneiro[1], Claudio Meneses[2], Gabriella Gee[1], Leon Melo[1], Nathan C. Peters[1]

[1]Snyder Institute for Chronic Diseases, Department of Microbiology, Immunology, and Infectious Diseases, Cumming School of Medicine and Faculty of Veterinary Medicine, University of Calgary, Canada, Calgary, AB, Canada, [2]Vector Molecular Biology Section, Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, USA, Rockville, MD, United States

The immunological environment primed by pre-exposure to uninfected sandfly bites is thought to have a significant impact on infection by the sand fly vector transmitted parasitic pathogen Leishmania. However, the nature of the immune response to uninfected vector bites and how this response changes over the life history of a mammalian host is poorly understood. We investigated the immune response elicited by exposure to the bites of uninfected Lutzomyia longipalpis sandflies. As previously shown, short-term exposure to sandfly bites activated salivary antigen-specific interferon (IFN)-gamma-producing dermal-derived CD4+ Th1 cells. However, upon repeated exposure, the immune response underwent diversification at the population level to include multiple salivary antigen specific CD4+ subsets (Th1, Th2, Th17, and TREG) and enhanced IL-5 production. Analysis of delayed-type hypersensitivity (DTH) at the bite site during ongoing chronic exposure revealed four phases of DTH, the last of which correlated with a high degree of immunoregulation, a local inflammatory cell infiltrate comprised primarily of eosinophils, an alteration in the maturation of inflammatory monocytes, and enhanced disease upon subsequent challenge with Leishmania plus salivary gland homogenate (SGH). Employing mice genetically deficient in T cells (TCR-/-), Th2 immunity (STAT6-/-), or Eosinophils (GATA-1-/-) revealed that long-term exposure to uninfected bites primes a T cell dependant Th2 response characterized by eosinophil infiltration. GATA1-/- and STAT6-/- deficiency resulted in decreased inflammation, decreased generation of M2-like monocytes-derived macrophages, fewer eosinophils, and enhanced IFN-g response. Disease exacerbation mediated by long-term exposure was found to be dependent on IL-5, as anti-IL-5-mediated reduction of eosinophils resulted in improved control of Leishmania infection. These results show that IL-5-induced eosinophilia mediated by T cells/STAT6 following exposure to uninfected bites influences the virulence of a vector transmitted disease.

DISSECTING PROTECTIVE NK CELL RESPONSES TO TRYPANOSOMA CRUZI INFECTION IN THE HUMAN SKIN

Jessica Barton[1], Keshia Kroh[1], Helena Fehling[2], Hanna Lotter[2], Andrea Vanegas Ramirez[3], Beate Volkmer[4], Rüdiger Greinert[4], Thomas Jacobs[1], **Rosa I. Gálvez**[1]

[1]Protozoa Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]Department of Molecular Biology and Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [3]Department of Dermatology, Bundeswehr Hospital Hamburg & Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [4]Centre of Dermatology, Elbe Clinics Buxtehude, Buxtehude, Germany

Chagas disease is caused by the protozoan parasite Trypanosoma cruzi. It is mainly prevalent in Latin America and is classified as one of the most neglected tropical diseases. Since T. cruzi parasites are mainly transmitted by blood-sucking triatomine bugs, the skin is the main entry route and the first affected organ. Although homeostasis and immunosurveillance of this important anatomic site are crucial to limit parasite burden, the initiation of the local immune response in the skin, as well as the systemic consequences of these early events, remain elusive. Due to the obligatory intracellular life cycle of T. cruzi, natural killer (NK) cells substantially contribute to the control of parasite spread. Therefore, our study aimed to dissect the response of human NK cells to T. cruzi infected non-immune cells resident in the skin, mainly fibroblast and keratinocytes. For this purpose, we established in-vitro cultures of primary human cells, characterized T.cruzi infections, and performed NK cell co-cultures. Our findings describe for the first time and in a comprehensive manner how NK cells sense T.cruzi infection in the human skin. We found remarkable differences in the expression of NK ligands between infected keratinocytes and fibroblasts. Furthermore, we demonstrate that T. cruzi infected primary human skin cells promote NK cell degranulation and show how NK cells orchestrate the following immune response by differential cytokine release. Finally, we performed transcriptome analysis of infected fibroblasts and identified pathways leading to contact-independent activation of NK cells. Taken together, we established reliable in-vitro models to study mechanisms of the NK cell response to T. cruzi infected human skin cells and identified crucial receptors for NK cell activation, which are presumably responsible for the containment of parasite spread in the skin during acute infection. Understanding the contribution of NK cells to parasite control and the mechanisms affecting NK cell function can contribute to target natural killer cells as enhancers of vaccine responses and to develop new therapeutic options.

INHIBITION OF SRC SIGNALING INDUCES AUTOPHAGIC KILLING OF TOXOPLASMA GONDII INDEPENDENT OF EGF RECEPTOR

Alyssa Hubal[1], Jose-Andres Portillo[1], Anusha Vendhoti[1], Sarah Vos[1], Charles Shaffer[2], Carlos Subauste[1]

[1]Case Western Reserve University School of Medicine, Cleveland, OH, United States, [2]Case Western Reserve University, Cleveland, OH, United States

Toxoplasma gondii is an intracellular parasite that can cause severe disease in both immunocompromised and immunocompetent patients, affecting organs such as the brain and eye. T. gondii avoids degradation by the autophagolysosome by manipulating signaling pathways that promote autophagy. Previous studies have shown that the parasite activates EGFR to prevent targeting by autophagy. It is unclear if T. gondii manipulates alternative mechanisms independent of EGFR to avoid autophagic targeting, an important question since various cells in the brain and retina have little to no expression of EGFR. Our study found that T. gondii activates Src and Akt in cells that lack EGFR expression. Genetic or pharmacological inhibition of Src with Saracatinib impaired T. gondii-induced phosphorylation of Src and Akt. Low-dose Saracatinib and knockdown of Src resulted in the accumulation of autophagosomal and lysosomal markers (LC3 and LAMP1, respectively) and promoted killing of T. gondii dependent on the autophagy protein ULK1 and lysosomal enzymes. T. gondii-dependent activation of Src deactivated PTEN promoting PI3K/Akt signaling that prevented autophagic targeting of the parasite. Inhibition of Src disrupts this pathway and allows for autophagic killing of T. gondii. Saracatinib administration to mice with pre-established ocular and cerebral toxoplasmosis reduced histopathology and parasite loads in the eye and brain without altering cell-mediated or humoral immunity. In conclusion, T. gondii can activate Src - Akt signaling to prevent autophagic eradication independently of EGFR. Inhibition of Src may have therapeutic applications against ocular and cerebral toxoplasmosis.

LOSS OF SIGLEC-7 CORRELATES WITH ENHANCED NATURAL KILLER CELL FUNCTION AND PROTECTION FROM MALARIA SYMPTOMS

Jenna Dick[1], Jules Sangala[1], Benjamin Zandstra[1], Peter Crompton[2], Geoffrey Hart[1]

[1]University of Minnesota, Minneapolis, MN, United States, [2]National Institutes of Health, Bethesda, MD, United States

An effective malaria vaccine is urgently needed, but progress towards this goal has been hampered by our limited understanding of the factors responsible for effective malaria immunity. Malaria is a parasitic disease caused by the parasite Plasmodium. Natural killer (NK) cells inhibit the growth of Plasmodium in vitro through antibody dependent cellular cytotoxicity (ADCC). We went on to show that a subset of NK cells in malaria endemic subjects, known as adaptive NK cells, lack the Fc receptor γ chain (FcRγneg) have enhanced ADCC function. However, it was unclear if the lack of Fc γ chain was the reason for increased functionality or if it only served as a marker for adaptive NK cells. Our goal was to know why adaptive NK cells have enhanced cytotoxic function in malaria. Therefore, we developed a CRISPR/Cas9 protocol to ablate genes associated with ADCC in primary NK cells. We then evaluated the effect of those ablations on NK cell function and found that the absence of FcRγ does not enhance NK cell ADCC. We then searched for other alterations in adaptive NK cells in malaria subjects that correlated with enhanced ADCC function. We found that a decrease in the expression of the inhibitory receptor Siglec-7 (Sialic Acid Binding Ig-like lectin 7) correlated with increased NK ADCC function in individuals with a history of malaria infection. Importantly, Sigelc-7 negative NK cells correlated with FcRγneg NK cells in malaria. Because Siglec-7 is an inhibitory receptor, we hypothesized that when the NK cells lack this receptor, this could be cause for adaptive NK cell increased function. We then ablated Siglec-7 using CRISPR/Cas9 and found enhanced ADCC functionality and enhanced killing of Plasmodium-infected red blood cells. Therefore, we predict Siglec-7 is an important protein of interest to study for the protective effects of NK cells in malaria. This is further supported as unaffected individuals without a history of malaria infection did not have a decrease in Siglec-7 expression. The ultimate goal is to use this data to leverage insights from NK cell protective mechanisms to create better therapeutics and vaccines for malaria.

GUT MICROBIOTA-DERIVED METABOLITES ALTER HUMAN-DERIVED MACROPHAGE STIMULATION AND MAY INCREASE IMMUNE RESPONSES TO ORAL CHOLERA VACCINE

Denise Chac[1], Susan M. Markiewicz[1], Ashraful I. Khan[2], Fahima Chowdhury[2], Emily Pruitt[1], Taufiqur R. Bhuiyan[2], Regina C. LaRocque[3], Jason B. Harris[3], Libin Xu[1], Edward T. Ryan[3], Firdausi Qadri[2], Ana A. Weil[1]

[1]University of Washington, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Massachusetts General Hospital, Boston, MA, United States

Immune responses to oral cholera vaccines (OCV) vary among individuals; studies of host factors have only partially explained these differences. We have observed correlations between gut microbes and responses to OCV

in persons receiving two doses of OCV (Shanchol) in Dhaka, Bangladesh, a cholera-endemic area. We previously found that OCV recipients with specific gut microbial profiles were predictive of Vibrio cholerae O-specific polysaccharide memory B cell responses (OSP MBC), a response known to be correlated with protection. Interestingly, the microbes most correlated with OSP MBC produce sphingolipids (SL). To test the association of SL and OCV responses, we isolated microbes from the stool of vaccine recipients that produce SLs including Bacteroides species. Lipids extracted from cultures of Bacteroides xylanisolvens were then applied to human-derived macrophages, a model of mucosal innate immune responses that may contribute to the development of OSP MBC after OCV. We found lower production of interleukin-6 (IL-6) and other inflammatory cytokines after microbe-derived SLs were applied to the model, compared to lipid layers in which SL synthesis was inhibited ($P<0.0001$, t test). This indicates a lower level of baseline innate immune activation in the model when SLs are present. We hypothesize that this low level of baseline stimulation at the mucosal surface (i.e. when microbe-derived SL are present) may increase responsiveness to vaccine antigen. We tested this by preconditioning our model with microbe-derived SLs and then applying lipopolysaccharide (LPS) for 24 hours. Macrophages preconditioned with microbe-derived SL had greater IL-6 production ($P=0.0003$, t test) after stimulation with LPS compared to cell preconditioned with bacterial lipids lacking SL, indicating that the innate immune response to LPS was greater in the presence of microbe-derived SL. Here, we have identified SL-producing microbes isolated from vaccine recipients that correlate with OSP MBC responses in OCV recipients and found that lipids from these microbes impact innate immune responses to vaccine antigens in vitro.

5703

TITLE: ASCERTAINING TRUE CHOLERA BURDEN AND SUBNATIONAL CHOLERA RISK WITH A NOVEL CONTINUOUS DISEASE ENDEMICITY INDEX

Neda Jalali[1], Sandra Mendoza Guerrero[2], Andrew Azman[3], Elizabeth Lee[3], Steven Stoddard[4], Sean Moore[1]

[1]University of Notre Dame, South Bend, IN, United States, [2]Emergent BioSolutions, Gaithersburg, MD, United States, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Emergent BioSolutions, Redwood City, CA, United States

Despite efforts to control and eliminate cholera, it continues to impose large public health impacts in low and middle-income countries. Implementing effective and efficient intervention programs to control cholera in affected regions relies on knowing the actual cholera burden. The current WHO cholera endemicity definition is defined as having reported cholera within three of the past five years, which is subject to bias because of discrepancies in national-level reporting to the WHO. We introduce a novel endemicity index using 20 years of cholera data extracted from publications, WHO, and national ministries of health reports. The index is the sum of the product of weighted reported years and annual incidence rates at national and subnational levels where the years' weights are calculated using a truncated Gaussian distribution. We used Gradient Boosted regression incorporating environmental and socio-economic covariates, potentially associated with cholera occurrence, and a spatial random effect for countries to estimate the endemicity index for subnational regions without adequate cholera data. The endemicity index predictions were largely consistent with previous estimates of endemicity in both endemic and non-endemic areas. Within Africa, Eastern and Central Africa are estimated to have persistent cholera, while western Africa is at a lower risk of cholera transmission except for portions of Liberia and Nigeria. Southern China, the northern provinces of India, Bangladesh, and the Philippines are regions that are at a higher risk of cholera in South East Asia. The endemicity index indicated 29 out of 186 countries are highly endemic (have at least one subnational region with an endemicity index greater than zero), and in 8 of these 29 countries, this held true for 90% or more of their subnational regions. In addition, 11 out of 186 countries showed moderate risk of endemic transmission (an endemicity index between (-5,0)). Our results will help public health agencies to identify cholera-endemic regions, estimate the true cholera burden in these regions, and direct intervention programs to these areas more effectively.

5704

ENHANCED CHOLERA SURVEILLANCE AS A TOOL FOR IMPROVING VACCINATION CAMPAIGN EFFICIENCY

Hanmeng Xu[1], Kaiyue Zou[1], Juan Dent[1], Kirsten E. Wiens[2], Espoir B. Malembaka[1], Lee Hampton[3], Andrew S. Azman[1], Elizabeth C. Lee[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Temple University, Philadelphia, PA, United States, [3]Gavi, the Vaccine Alliance, Geneva, Switzerland

Oral cholera vaccines (OCVs) are effective in reducing risk of cholera caused by Vibrio cholerae O1 and deployed increasingly for preventive vaccination campaigns, although global demand has exceeded global supply in recent years. Systematic testing for V. cholerae O1 is rare, even in high burden cholera surveillance systems, which means that the limited supply of vaccines may not be delivered to areas with the highest true cholera burden. We explored the effect of increasing V. cholerae testing capacity on OCV campaign impact using a spatial modeling framework that simulates detection, vaccine targeting, susceptibility and burden for projected cholera in 35 African countries from 2022-2035. We compared public health impact, vaccination campaign efficiency (number of true cholera cases averted per 1,000 fully vaccinated persons), and cost-effectiveness across 18 vaccination scenarios with different assumptions about bacteriological confirmation capacity and OCV targeting strategy. When districts with an observed cholera incidence rate exceeding 10 per 10,000 population were targeted with OCV, in scenarios with and without systematic V. cholerae testing, 29 million (95%PI: 21-37 million) and 71 million (95%PI: 65-78 million) individuals were fully vaccinated and 19% (95%PI: 15-22%) and 25% (95%PI: 22-27%) of true cases were averted to yield 10.3 (95%CI: 8.3-13.0) and 5.6 (95%CI: 4.6-6.7) averted cases per 1,000 fully vaccinated persons, respectively; increasing testing cost by $37 (95%PI: 29-52) per averted case reduced OCV campaign costs by $376 (95%PI: 275-556). Compared to status quo, which targets OCV to areas with high clinical cholera incidence rates, expanding V. cholerae testing capacity and targeting OCV campaigns to areas with the highest incidence rate of test-positive V. cholerae has the potential to greatly improve the efficiency and cost-effectiveness of OCV campaigns, while averting nearly as many true cholera cases and using far fewer vaccines. Integration of systematic testing into cholera surveillance, including use of rapid diagnostic tests, could improve efficiency and reach of current global supply of OCV.

RE-EMERGENCE OF CHOLERA IN HAITI LINKED TO ENVIRONMENTAL VIBRIO CHOLERAE O1 OGAWA STRAINS

Carla N. Mavian[1], Massimiliano Tagliamonte[1], Meer T. Alam[1], Nazmus Sakib[1], Melanie N. Cash[1], Juan Perez Jimenez1[1], Alberto Riva[1], Eric J. Nelson[1], Emilie T. Cato[1], Jayakrishnan Ajayakumar[2], Andrew Curtis[2], V. Madsen Beau De Rochars[1], Vanessa Rouzier[3], Jean William Pape[3], J. Glenn Morris Jr[1], Marco Salemi[1], Asfar Ali[1]

[1]University of Florida, Gainesville, FL, United States, [2]Case Western Reserve University, Cleveland, OH, United States, [3]Weill Cornell Medical College, Les Centres GHESKIO Haiti, New York, NY, United States

Cholera was introduced in Haiti in October 2010. Between February 2019 and August 2022, no further cholera cases were registered. On September 25th, 2022, a new outbreak occurred in the Ouest Department of Haiti, where our group previously demonstrated the establishment of an environmental reservoir of toxigenic V. cholerae O1 in the aquatic ecosystem and its active role in fuelling the epidemic during lull periods. We investigated the origin of the new outbreak by analyzing the full genome sequence of 41 Vibrio cholerae O1 toxigenic Ogawa strains isolated between October 3rd November 21st, 2022 collected by GHEISKIO. We performed maximum likelihood phylogenetic analysis of 2,129 toxigenic V. cholerae O1 sampled worldwide, from 1937 to 2022, and in-depth

Bayesian phylogenetic and molecular clock analysis of 31 new strains obtained from Haiti in 2018, at the nadir of the previous outbreak, as well as 294 Haitian strains sampled between 2010 and 2017, and 16 sequences from the 2022 outbreak publicly available. Our phylogenetic analysis firmly shows the new strains clustering within the Haitian monophyletic clade that emerged at the time of the 2010 outbreak. Our Bayesian phylogenetic also demonstrated that the new strains of V. cholerae cluster shared a most recent common ancestor with a 2018 Haitian Ogawa strain isolated from the aquatic ecosystem and cluster with the previous Ogawa clade that was circulating in 2015-2016. Our case data points out to the original epicenter of the outbreak in Port-Au-Prince and the exponential spread in different directions. Our phylogeography analyses based on the plateau phase of the epidemic, shows further spread within Port-Au-Prince and towards outside. In conclusion, our results show that the new outbreak strains originated from strains that have been circulating undetected at sub-epidemic levels in the aquatic environment. Our data strongly indicates that re-emergence of cholera in Haiti is the likely result of a spill-over event at the aquatic-human interface related to persistence of V. cholerae O1 in the environment.

5706

EFFECTIVENESS OF THE EUVICHOL® ORAL CHOLERA VACCINE AT 2 YEARS: A CASE-CONTROL AND BIAS-INDICATOR STUDY IN HAITI

Wilfredo R. Matias[1], Yodeline Guillaume[1], Gertrude Cene Augustin[2], Kenia Vissieres[2], Ralph Ternier[2], Damien M. Slater[1], Jason B. Harris[1], Molly F. Franke[3], Louise C. Ivers[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]Zanmi Lasante, Port-au-Prince, Haiti, [3]Harvard Medical School, Boston, MA, United States

The World Health Organization (WHO) recommends use of oral cholera vaccine (OCV) in cholera control efforts. Studies of Shanchol® - a bivalent killed whole-cell OCV - have established its effectiveness in preventing cholera. Euvichol®, a similar product, was pre-qualified by WHO in 2016 and is now the leading component of the Global OCV stockpile, but data on its field effectiveness are limited. Between November - December, 2017, a Euvichol® campaign was implemented in Haiti. We conducted a case-control study to evaluate the effectiveness of this OCV, and a bias-indicator study to evaluate likelihood of study bias. Residents of Mirebalais, Haiti who were eligible for vaccination were enrolled beginning 10 months after the vaccination campaign. Cases were individuals presenting to a cholera treatment unit with acute watery diarrhea (AWD). Stool samples were tested by culture and RT-PCR of the V. cholerae O1 cholera toxin gene. For each case, four control individuals without diarrhea were matched by location of residence, enrolment time, age and sex. Participants were interviewed for sociodemographics, cholera risk factors, and self-reported vaccination. Cholera cases were analyzed in the vaccine effectiveness (VE) study. AWD cases negative for cholera by culture and RT-PCR were analyzed in the bias-indicator study. Data were analyzed by conditional logistic regression, adjusting for matching factors. From 9/12/2018 - 3/12/2020, we enrolled 100 AWD cases. 18 had cholera and were matched to 72 controls. 82 cases without cholera were matched to 325 controls. In the VE case-control, 10 (55.6%) cases reported vaccination compared to 54 (75%) controls. Adjusted VE for 2 doses of OCV was 62% (-67 - 91%). VE for 2 doses of OCV in the bias-indicator study was 40% (-12 - 68%). Between 10 - 27 months after vaccination, Euvichol® was effective at preventing cholera. VE estimates and bias-indicator estimates for Euvichol® in Haiti are comparable to prior estimates of Shanchol® in Haiti, which demonstrated robust evidence of VE up to 2 years post-vaccination. Further research to evaluate the effectiveness of OCV in children and over longer periods are needed.

THE EFFECTIVENESS OF ONE DOSE OF ORAL CHOLERA VACCINE: MATCHED CASE-CONTROL STUDIES FROM UVIRA, DEMOCRATIC REPUBLIC OF CONGO

Espoir Bwenge Malembaka[1], Patrick Musole Bugeme[1], Chloe Hutchins[2], Hanmeng Xu[1], Juan Dent Husle[1], Maya N. Demby[1], Karin Gallandat[2], Jaime M. Saidi[3], Baron Bashige Rumedeka[1], Moïse Itongwa[1], Esperance Tshiwedi[4], Faida Kitoga[4], Amanda K. Debes[5], Justin Lessler[6], Oliver Cumming[2], Placide O. Welo[7], Daniel Mukadi-Bamuleka[4], Jackie Knee[2], Andrew S. Azman[1]

[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Department of Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Zone de Santé d'Uvira, Ministère de la Santé Publique, Uvira, Congo, Democratic Republic of the, [4]Institut National de Recherche Biomédicale, Goma, Congo, Democratic Republic of the, [5]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Department of Epidemiology, Gillings School of Global Public Health, and University of North Carolina Population Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [7]PNECHOL-MD, Community IMCI, Ministry of Health, Kinshasa, Congo, Democratic Republic of the

Amid a global surge in cholera outbreaks and shortage in oral cholera vaccines (OCV), a single-dose regimen, rather than the standard two-dose regimen, is being used in outbreaks. However, single-dose protection data are limited, especially for children and durations of longer than a few months. We conducted two case-control studies in Uvira, Democratic Republic of Congo, to examine the vaccine effectiveness (VE) of a single-dose of the Euvichol-plus vaccine up to 29 months after vaccination. We recruited matched community controls for confirmed cholera cases admitted at health facilities 12-17 months after vaccination, from October 2021 to March 2022 (Study 1). We then prospectively enrolled community controls for cases admitted 24-29 months after vaccination, from October 2022 to March 2023 (Study 2). Eligible cases included culture and/or PCR-confirmed cholera cases who were eligible for the vaccine during the vaccination campaigns. Four controls with no history of cholera in the past 3 years were matched to each case by age, sex, and neighborhood, as well as by household size and presence of a child under-5 in Study 2. We used conditional logistic regression to estimate VE. We enrolled 1202 participants (268 cases, 934 controls) in Study 1 and 855 participants (167 cases, 688 controls) in study 2 with 18% of the cases being <5 years old in Study 1 and 30% in Study 2. The adjusted single-dose effectiveness for all ages was 50.6% (95% CI 30.1-65.2%) 12-17 months after vaccination and 37.7% (5.5-58.9%) 24-29 months after. VE point estimates were similar across age groups in both studies. Estimates for children under 5 years old were 45.1% (-39-78%) in Study 1 and 43% (66-80%) in Study 2, compared to estimates for older participants of 49% (25-65%) in Study 1 and 41% (3-65%) in Study 2. We demonstrate significant clinical protection from a single dose of Euvichol-plus both one and two years after vaccination. While uncertainty remains around the protection conferred to children under 5, these provide important new data to help with the planning of future vaccination campaigns.

5708

SINGLE DOSE ORAL VAXCHORA VACCINE (CVD103-HGR) FOR THE PREVENTION OF CHOLERA IN TRAVELERS

James M. McCarty[1], Lisa Bedell[2]

[1]Stanford University, Stanford, CA, United States, [2]Emergent BioSolutions, Gaithersburg, MD, United States

Cholera remains an ongoing threat for travelers to areas with endemic/epidemic Vibrio cholerae infections. A single dose vaccine which provides rapid protection, especially for those leaving on short notice, is desirable. To assess the safety, immunogenicity and efficacy of Vaxchora® (Cholera Vaccine, Live, Oral) for protection against cholera diarrhea in travelers, 5 prospective, randomized, double-blind, placebo-controlled trials were performed in 4357 subjects 2-64 years of age in

the US. Endpoints included safety, immunogenicity, shedding, protective efficacy, lot consistency, and immunologic bridging following a single dose. The phase 1 study documented serum vibriocidal antibody (SVA) seroconversion in 88.9% of subjects at day 14, and stool shedding of vaccine organisms in 11% through day 7. In a phase 3 study, protective efficacy against moderate-to-severe diarrhea following challenge with virulent V. cholerae was 90.3% and 79.5% at days 11 and 91, respectively. SVA seroconversion, which occurred in 79.8% and 89.4% of subjects at days 8 and 11, respectively, was a strong correlate of protection. In a phase 3 lot consistency study, SVA seroconversion occurred in 93.5% of adults 18-45 years of age at day 11, while a phase 3 immunogenicity study in older adults 46-64 years demonstrated a non-inferior 90.4% seroconversion rate. A phase 4 study in children 2-17 years of age demonstrated a 98.5% SVA seroconversion rate, which was non-inferior to that seen in the lot consistency study. An adolescent sub-study of the pediatric trial documented persistence of SVA seroconversion at 2 years in 64.5% of vaccine recipients. In a post-hoc analysis of the pediatric trial of those subjects who consumed less than the full dose of vaccine, SVA seroconversion was documented in 100% of those who took 50-80% of the dose and in 69.2% of those who took some but <50%. Vaccine was well tolerated in all studies. A single oral dose of Vaxchora vaccine provides safe and rapid protection in adults and children traveling to areas with cholera. SVA seroconversion, the correlate of protection in the cholera challenge trial, occurs in most individuals in as little as 7 days.

Long-term post-acute sequelae following viral infections have become recognized as highly prevalent in recent years, including in the contexts of Ebolavirus disease (EVD) and SARS-CoV2. As these diseases continue to emerge—Sudan ebolavirus (SUDV) in Uganda; Marburg virus (MARV) in Equatorial Guinea—the long-term health consequences following acute infection are garnering attention. In the context of EVD, a large proportion of survivors develop a range of long-term sequelae with complaints including ophthalmologic, auditory, musculoskeletal (MSK), neurocognitive, and psychiatric. Our group recently defined these sequelae phenotypically into three groups: symptomatic survivors with or without MSK involvement, and asymptomatic. The mechanisms defining long-term sequelae, including MSK, are currently unknown making targeted treatment challenging. Due to the association of inflammatory biomarkers with MSK sequelae in other viral contexts (ie: HIV/AIDS and Chikungunya virus), we developed a 20-plex Luminex panel to assess the relationship between inflammatory markers and MSK sequelae in an ongoing cohort of EVD survivors from Eastern Sierra Leone. Our custom Luminex panel included pro- and anti-inflammatory cytokines, metalloproteinases, and markers of mucosal integrity associated with inflammation. We found that contrary to our hypothesis of increased inflammation in survivors suffering from long-term MSK, that in fact survivors with MSK had lower concentration of serum biomarkers compared to asymptomatic EVD survivors. In collaboration with colleagues at WSU, we tested antibody driven Fc-mediated innate effector function and observed significantly lower levels of monocyte/macrophage phagocytosis and decreased complement deposition in survivors in the MSK group. We are currently investigating alternative hypotheses including the presence of autoantibodies, a phenomenon that has been observed in the context of SARS-CoV2 following recovery from acute disease. Our preliminary data suggest an immune dysregulation and possible immunosenescence associated with long-term MSK sequelae in EVD survivors.

EXPLORING BAT INNATE IMMUNE CELL RESPONSES TO FILOVIRUSES

Ivet A. Yordanova[1], Jonathan C. Guito[2], Markus Kainulainen[2], César Albariño[2], Jonathan S. Towner[2], Joseph B. Prescott[1]

[1]Center for Biological Threats and Special Pathogens, Robert Koch Institute, Berlin, Germany, [2]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States

Various species of bats are reservoirs of diverse zoonotic viruses, including multiple filoviruses such as Marburg virus (MARV, naturally transmitted by Egyptian rousette bats; Rousettus aegyptiacus) and Bombali ebolavirus (BOMV, recently isolated from Angolan free-tailed bats; Mops condylurus). The ability of bats to host viruses that are highly-pathogenic to humans likely correlates with co-evolved functional anti-viral immune response mechanisms. How bats achieve efficient anti-viral innate or adaptive immune responses at the molecular or cellular level, without developing overt signs of disease themselves, remains to be addressed. In this study, we profile the phenotypes, functionality and anti-viral immune responses of dendritic cells (DC), key primary host cellular targets of filoviruses. We infected bone marrow-derived DCs (bmDCs) from R. aegyptiacus with recombinant MARV or Sudan ebolavirus (SUDV) expressing fluorescent proteins, allowing us to directly compare how DCs respond to infection by a filovirus that these bats harbour in nature (MARV), to a filovirus efficiently cleared by rousette bats in vivo (SUDV). Despite similar rates of progeny virus production, bmDCs supported increased intracellular MARV-ZsG replication out to 3 days post-infection, while ZsG median fluorescence intensity (MFI) in SUDV-infected bmDCs was decreased, indicating differential control of infection of these two viruses. Conversely, MARV- and SUDV-infected bmDCs both upregulated CD40 and HLA-DR surface expression, indicative of functional cell activation. Similarly, bmDCs from M. condylurus sustained steady rates of replication with fluorescently-tagged Zaire ebolavirus (EBOV-GFP) and displayed a notable upregulation of CD40 at 1 day post-infection. Our findings highlight that despite being susceptible to infection, bat DCs display unimpaired activation and antigen presentation capacities following disparate filovirus infections, in contrast to the described impaired maturation and functionality observed in filovirus-infected human DCs.

Waning immunity and emerging variants necessitate continued vaccination against SARS-CoV-2. Improvements in vaccine efficacy, safety, tolerability, and ease of manufacturing would benefit these efforts. Receptor-binding domain (RBD)-based vaccines are effective vaccines used in several

countries, in part due to their ease of manufacturing. Here, we report a novel computational design strategy (SPEEDesign) that improves RBD vaccines. SPEEDesign was used to create RBD immunogens with amino acid changes that enhance neutralizing antibody titers, focus the immune response to neutralizing epitopes, increase production yields, and improve antigen stability. In one application of SPEEDesign, immunogens with 9 amino acid changes elicited neutralizing antibody titers approximately 10-fold greater than the native RBD, and comparable to a benchmark stabilized spike antigen. Crystal structures of these immunogens revealed the structural basis for these improvements. A second application of SPEEDesign produced a stabilized, non-glycosylated RBD that resolved issues hindering the efficient nanoparticle display of the native RBD. This non-glycosylated RBD can be genetically fused to diverse single-component nanoparticle platforms maximizing manufacturing ease and flexibility. All engineered RBD-nanoparticles elicited potently neutralizing antibodies in mice that far exceeded monomeric RBD. A 60-copy particle (noNAG-RBD-E2p) also elicited potently neutralizing antibodies in non-human primates. The neutralizing antibody titers elicited by noNAG-RBD-E2p were comparable to a benchmark stabilized spike antigen and reached levels against omicron BA.5 that suggest it would provide protection against emerging variants. The stabilizing mutations we have identified in both applications of SPEEDesign are adaptable to all vaccine platforms and they are distinct from the changes in emerging variants, making them compatible with updated vaccines. Finally, the SPEEDesign pipeline is a generalizable method that can be used to improve vaccine antigens from diverse pathogens.

EPSTEIN BARR VIRUS SYNERGIZES WITH PLASMODIUM FALCIPARUM MALARIA TO INDUCE ABERRANT EXPRESSION OF ACTIVATION INDUCED CYTIDINE DEAMINASE

Bonface Ariera, Sidney Ogolla, Rosemary Rochorford

University of Colorado Anschutz medical campus, Aurora, CO, United States

Early age at EBV infection and repeated episodes of Plasmodium falciparum (Pf) malaria are known risk factors for the development of endemic Burkitt's lymphoma(eBL), the most common pediatric cancer in equatorial Africa. To date, the extent and by what means these two factors interact to drive eBL pathogenesis is yet to be fully understood. Both EBV and P.f have been considered as potential drivers of increased Activation Induced Cytidine Deaminase (AID) activity, the major hallmark of eBL. AID activity is typically restricted to B cells in the germinal center reaction. However, recently low levels of AID expression in immature transitional B cells in peripheral circulation have been reported. Additionally, AID expression has been reported in B cells in peripheral circulation in children and adults from malaria endemic areas. Studies in vitro and in mice have also demonstrated either P.f or EBV can induce expression of AID in peripheral blood. In this study, we hypothesized that EBV and P.f malaria synergistically induce dysregulated expression of AID. We analyzed the expression of AID on B cells from peripheral blood of children experiencing an episode of acute P.f malaria and healthy controls by intracellular flow cytometry. Furthermore, we determined the in vitro induction of AID expression on primary human B cells following infection with EBV with or without CpG (a TLR9 ligand used to mimic P.f DNA). We report a significantly higher frequency and MFI of CD19+ AID+ B cells in children presenting with acute malaria than in healthy controls. In vitro analysis confirmed the synergy between EBV and P.f malaria in the amplification of AID expression since we observed >50% increase in the frequency of CD19+AID+ cells following infection with EBV and CpG. Interestingly, co-stimulation with BAFF, a B-cell cytokine that is elevated during acute malaria infection, further amplified the expression of AID in B cell in vitro. Taken together, our study confirms the synergistic linkage between these two pathogens in the etiology of eBL through the induction of aberrant expression of the highly mutagenic AID that is likely to exacerbates the pathogenesis of eBL.

ANTIBODY FC CORRELATES OF PROTECTION AGAINST SEVERE DENGUE DISEASE

Elias M. Duarte[1], Antonio G. Dias Jr[1], Jose Victor Zambrana[2], Sandra Bos[1], Vicky Roy[3], Rosie Aogo[4], Leah Katzelnick[4], Guillermina Kuan[5], Angel Balmaseda[6], Galit Alter[3], Eva Harris[1]

[1]Division of Infectious Disease and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [3]Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States, [4]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [5]Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua, [6]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Four dengue virus serotypes (DENV1-4) are associated with ~50 million cases annually worldwide, with disease presenting as mild (dengue fever, DF) or severe (dengue hemorrhagic fever/shock syndrome, DHF/DSS). Pre-existing cross-reactive antibodies have been associated with both protection and risk for developing severe dengue upon secondary heterotypic infection, but antibody characteristics that provide protection from severe disease remain poorly understood. We performed systems serology on plasma/serum samples collected from 66 individuals (33 DF and 33 DHF/DSS) before secondary DENV2 and DENV3 infections resulting in either DF or DHF/DSS from a longstanding pediatric cohort study in Nicaragua. We measured binding antibodies by Luminex using beads conjugated to recombinant envelope (E), E domain III, and nonstructural protein 1 (NS1) of DENV1-4 and the related Zika virus (ZIKV). For Fc effector function assays, we used beads conjugated to DENV2, DENV3, and ZIKV antigens. Our study revealed that higher levels of total IgG, IgG2, IgG3, IgG4, and both antibody-dependent complement deposition (ADCD) and antibody-dependent cellular phagocytosis (ADCP) were associated with protection against DHF/DSS. In contrast, neutralizing antibodies to mature DENV2 and DENV3 virions, measured by focus reduction neutralization test on Vero cells, were not significantly different. We also observed a stronger association of ADCD activity with protection when assays were conducted with ZIKV antigens. We validated these findings with a complement-mediated virolysis assay using DENV, ZIKV or yellow fever virus virions. We found that virolysis of ZIKV virions mediated by samples from DENV-exposed, ZIKV-naïve individuals was most strongly associated with protection, suggesting that 1) anti-DENV antibodies that cross-react with ZIKV and 2) antibodies that target virion-specific epitopes are correlated with protection from severe dengue disease. In sum, our study provides important insights into the biophysical features and effector functions of cross-reactive antibodies that may inform the development of effective dengue vaccines.

5714

ANTIBODY CORRELATES OF SEVERE DISEASE IN SECONDARY DENGUE VIRUS INFECTION AFTER A PRIMARY ZIKA VIRUS INFECTION: A POSSIBLE ROLE FOR IGA

Jaime A. Cardona-Ospina[1], Sandra Bos[1], Gregorio Dias Jr.[1], Jose Victor Zambrana[2], Vicky Roy[3], Elias Duarte[1], Guillermina Kuan[4], Angel Balmaseda[5], Galit Alter[3], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [3]Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States, [4]Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua, [5]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Sequential infections of dengue virus serotypes 1-4 (DENV1-4) and Zika (ZIKV) can lead to protection or severe disease. We observed in our

long-standing pediatric cohort in Nicaragua that ZIKV infection increases risk of dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS) during secondary DENV2 infection, potentially due to antibody-dependent enhancement. However, immune correlates of disease severity are not completely understood. Here, we analyzed antibody characteristics in samples taken after primary ZIKV infection that were associated with DHF/DSS vs. dengue fever (DF) during subsequent secondary DENV2 infection in 24 children (n=12/group) from our Nicaraguan cohort study. We characterized anti-DENV and anti-ZIKV antibodies (IgG1-4, IgA, IgM) in pre-secondary infection samples using a multiplex Luminex assay against recombinant E protein (recE), E domain III, and nonstructural protein 1 (NS1) of DENV1-4 and ZIKV, as well as the Fc effector functions antibody-dependent complement deposition (ADCD) and antibody-dependent cellular phagocytosis. After modelling a dose-response curve, the effective dilution at which mean fluorescence intensity was reduced by 50% (ED50) was significantly associated with DHF/DSS for IgA but not for other isotypes. A bivariate logistic binomial regression showed that a 0.1Log10 increase in the ED50 of anti-NS1 DENV2 IgA and anti-NS1 ZIKV IgA, among others, increased odds of DHF/DSS by 3.07 (95% Confidence Interval [95%CI] 1.62-9.77) and 2.02 (1.31-4.34), respectively. A LASSO multivariate regression selected ED50of anti-NS1 DENV2 IgA as the most relevant feature associated with DHF/DSS. Finally, a Bayesian network analysis revealed that ED50 of anti-NS1 DENV2 IgA and anti-NS1 DENV4 IgA increased the probability of DHF/DSS. We are currently analyzing the amount of IgA1/IgA2 and dimeric vs. monomeric IgA, avidity of IgA against DENV/ZIKV antigens, and markers of neutrophil function in pre-secondary infection and acute-phase samples from these individuals. We hypothesize that IgA may be involved in a pathogenic pathway associated with DHF/DSS that deserves further study.

5715

IN-DEPTH ANALYSIS OF THE IMMUNOGENICITY OF A SINGLE DOSE OF DENGVAXIA IN BASELINE DENGUE-NAIVE CHILDREN IN CEBU, PHILIPPINES

Laura J. White[1], Lindsay Dahora[1], Elizabeth Adams[1], Emily Freeman[1], Lucas Laszacs[1], Ruby Shah[1], Lakshmanane Premkumar[1], Odio Camila[2], Leah Katzelnick[2], Jedas Daag[3], Maria Vinna Crisostomo[3], Kristal-An Agrupis[3], Michelle Ylade[3], Jacqueline Deen[3], **Aravinda de Silva**[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines, Manila, Philippines

The first licensed dengue virus (DENV) vaccine, Dengvaxia® sensitizes dengue seronegative (SN) children to experience more severe breakthrough infections compared to unvaccinated children. In clinical trials of this live attenuated tetravalent chimeric yellow fever/DENV vaccine, neutralizing antibodies (NAbs) to the 4 DENV serotypes were detected in most SN vaccinated individuals demonstrating that not all the antibodies that neutralize in vitro are predictive of durable protection in humans. When Dengvaxia® was introduced as a pediatric vaccine in the Philippines in 2016, investigators at the Univ. of Philippines in Manila established a cohort of 2,960 children (60% vaccinated) to study vaccine immunogenicity, efficacy and safety by baseline (BL) DENV serostatus over a 5-year follow-up period. Here we report the results of a sub-study to investigate vaccine immunogenicity in BL SN children 1 Year after receiving a single dose. We analyzed paired blood samples collected at BL and Yr1 from 136 vaccinated and 87 unvaccinated children using a) a multiplex-Luminex assay designed to measure antibodies to 8 DENV antigens (EDIII and NS1 proteins from the four serotypes), b) an ELISA for detecting Abs to yellow fever virus NS1 antigen expressed by the vaccine only, c) a DENV neutralization assay designed to measure NAb responses to contemporary circulating strains of mature DENV1-4. Among the vaccinated children we did not observe any vaccine-induced antibody responses in 34% (44/136) after one dose. Among the children who responded to the vaccine, the frequency of NAbs to each serotype was 66% (DENV4), 21% (DENV1), 15% (DENV2) and 10% (DENV3) supporting a DENV4 biased vaccine. We relied on the presence of DENV NS1 Abs as surrogate to capture all DENV infections in Yr1 blood samples. We observed a high attack rate of DENV infection (53%) between BL and Y1 in the unvaccinated children. Among the vaccinated children, 22% experienced DENV infections demonstrating modest efficacy against infection. Clinical vaccine efficacy and safety in years 1-5 after vaccination and immune correlates analyses are ongoing.

5716

ACUTE PUBLIC HEALTH THREATS GLOBALLY: A 10-YEAR WORLD HEALTH ORGANIZATION ANALYSIS

Saad[1], Blanche Greene-Cramer[1], Adedoyin Awofisayo-Okuyelu[1], Dubravka Selenic Minet[1], Maria Almiron[2], Krista Swanson[2], Masaya Kato[3], Tshewang Dorji[3], Tamano Matsui[4], Manilay Phenxay[4], Aura Corpuz[5], Jeremias Naiene[5], Jukka Pukkila[6], Silviu Ciobanu[6], Etien Koua[7], George Sie Williams[7], Oliver Morgan[8], Ibrahima Socé Fall[1], Abdi Rahman Mahamud[1], **Esther L. Hamblion**[1], on behalf of the World Health Organization Public Health Intelligence Teams[9]

[1]World Health Organization, Geneva, Switzerland, [2]World Health Organization Regional Office for the Americas, Washington DC, WA, United States, [3]World Health Organization Regional Office for South-East Asia, New Dehli, India, [4]World Health Organization Regional Office for the Western Pacific, Manila, Philippines, [5]World Health Organization Regional Office for the Eastern Mediterranean, Cairo, Egypt, [6]World Health Organization Regional Office for Europe, Copenhagen, Denmark, [7]World Health Organization Regional Office for Africa, Brazzaville, Congo, Republic of the, [8]World Health Organization, Berlin, Germany, [9]Opeayo Ogundiran,Jean-Pierre Kimenyi,Enrique Perez,Mahmoud Hassan,Ka Yeung Cheng, Lauren MacDonald,Amarnath Babu,Tika Sedai,Viema Biakula,Ariuntuya Ochirpurev,Alessandro Miglietta,Anastasia Smirnova,Etsub Tahelew,Harsh Lata,Kaja Kaasik, Lidia Ezerska,Tatiana Metcalf,Felix Moek, Switzerland

One of the World Health Organization's (WHO) key activities is the detection and response to acute public health threats to prevent morbidity and save lives. Therefore, WHO adopted a unique all-hazards approach to the global detection and verification of acute public health events of potential international public health concern, under the mandate of the International Health Regulations (2005). Here, we analysed 10-year trends of acute public health events globally. Data on substantiated acute public health events reported between 2013 and 2022 was extracted from an internal WHO platform, the Event Management System (EMS), which is used for tracking health threats globally. Substantiated events are those for which the presence of a hazard was confirmed or the number of human cases exceeded normal thresholds. These events were assessed, by WHO Region and over time, using descriptive statistics in R. Between 2013 and 2022, 3214 acute public health events were recorded globally in EMS, of which six were declared public health emergencies of international concern. For each year of the 10-year period, infectious diseases were the main cause of events, ranging from 68% - 90% per year. Globally the five most common infectious diseases, excluding COVID-19, were cholera, measles, dengue, zika, and avian or human influenza. Natural disasters (9.5%, N=305) were the second most common cause globally. In all WHO Regions infectious diseases were the main cause of public health events, ranging from 47%-84% between Regions. In addition, natural disasters were a common driver of events and the second cause, ranging from 9%-36%, in four of six Regions. Moreover, the proportion of events due to natural disaster has increased in recent years in these Regions. In conclusion, infectious diseases are the main cause of events globally reported to WHO. However, health emergencies by natural disasters are on the rise and marked differences, in health threats, between Regions exist. To prepare for future health threats an understanding of previous acute public health events and changing trends is key.

5717

DETECTION OF HUMAN CASES OF CRIMEAN-CONGO HEMORRHAGIC FEVER DURING AN ONGOING MULTIDISTRICT OUTBREAK OF EBOLA VIRUS DISEASE IN UGANDA, 2022-23

[1]Uganda Virus Research Institute, Entebbe, Uganda, [2]Viral Special Pathogens Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Ministry of Health, Kampala, Uganda, [4]Uganda Public Health Fellowship Program, Kampala, Uganda

In September 2022, Uganda experienced its 5th outbreak of Ebola virus disease (EVD) due to Sudan ebolavirus (SUDV) that spread to multiple districts across the country. During the subsequent national-wide enhanced surveillance activities, several cases suspected of viral hemorrhagic fever (VHF) were found to be caused by other viral etiologies, including yellow fever, Crimean-Congo Hemorrhagic fever (CCHF) and Rift Valley fever. We report the epidemiologic and laboratory findings of human CCHF cases that were concomitantly detected during the EVD response activities. A VHF suspected case was any person presenting with acute onset of fever (≥38.0°C), with no alternative diagnosis, and with other signs and symptoms such as intense fatigue, chills, general body pains, headache, anorexia, vomiting, diarrhea, jaundice, and unexplained bleeding from any site. Between September 2022 and February 2023, a total of 1,107 samples were submitted for VHF testing at Uganda Virus Research Institute, Entebbe, Uganda. Overall, 13 CCHF cases (including 7 deaths; CFR = 54%), aged 4 to 60 years, were identified by PCR from 10 districts, including the same districts as the SUDV outbreak. Of these, most cases were males who also engaged in livestock farming and exposure to wildlife (n = 8; 62%). Four cases were identified in the EVD treatment unit, thus complicating diagnosis and management of CCHF cases during an active SUDV outbreak. Among confirmed cases, the most common clinical symptoms were hemorrhage (n = 12; 92%), followed by fever (n = 11; 85%), anorexia (n = 10; 77%), fatigue (n = 9; 69%), abdominal pain (n = 9; 69%) and vomiting (n = 9; 69%). Further investigations to characterize these viral infections as well as alternate etiologies is ongoing and will be presented. These findings highlight the need for broad diagnostics for VHFs and other viral and high-consequence pathogens, even during confirmed VHF outbreaks, to properly identify all possible causes of acute febrile illnesses detected during periods of heightened surveillance. This approach is especially critical in countries with a broad range of endemic high-consequence zoonotic viral pathogens.

A COMPREHENSIVE REVIEW OF CLINICAL PRESENTATIONS OF NIPAH VIRUS INFECTION: EVIDENCE GENERATED FROM NIPAH VIRUS OUTBREAKS OF 2023, BANGLADESH

Syed M. Satter[1], Wasik R. Aquib[1], Arifa Nazneen[1], Dewan I. Rahman[1], Fateha A. Ema[1], Ahmed N. Alam[2], Mahbubur Rahman[2], Mohammad M. Rahman[2], Md O. Qayum[2], Mohammad R. Hassan[2], Ariful Islam[3], Sushmita Dutta[2], Nabila N. Chowdhury[2], Md Z. I. Noman[2], Abir S. Mahmood[2], Md S. B. Alam[2], Md M. Hassan[2], Immamul Muntasir[2], Sabrina J. Mily[2], Sakia Haque[2], Shownam Barua[2], Ahmad R. Sharif[2], Sharmin Sultana[2], John D. Klena[4], Mohammed Z. Rahman[1], Sayera Banu[1], Joel M. Montgomery[4], Tahmina Shirin[2]

[1]icddr,b, Dhaka, Bangladesh, [2]Institute of Epidemiology, Diseases Control and Research (IEDCR), Dhaka, Bangladesh, [3]EcoHealth Alliance, Atlanta, GA, United States, [4]Viral Special Pathogens Branch, Division of High Consequence Pathogens and Pathology, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Nipah virus is endemic to Bangladesh, and human infections have been reported almost every year since 2001. Till March 2023, Bangladesh experienced ten outbreaks of Nipah virus infection. Team of experts led by the Institue of Epidemiology, Disease Control and Research (IEDCR) conducted the outbreak investigations with support from icddr,b, and EcoHealth Alliance to detect more cases linked to the outbreaks and to prevent further spread in the community and healthcare setting. The teams identified the source of infection and obtained comprehensive information of the patients since their exposure to the virus. From January 4 to March 2, 2023, three clusters and seven sporadic Nipah outbreaks were identified from seven districts of Bangladesh. A total of 14 Nipah cases were reported, which included 86% (12/14) laboratory-confirmed and 14% (2/14) probable cases. There were 11 cases of primary infection, all with the history of raw date palm sap consumption prior to symptom onset. During the investigations, 675 contacts were identified; among them, three individuals were infected with the Nipah virus, indicating person-to-person transmission. On average, Nipah infection was confirmed 8 (range, 4 to 14) days after symptom onset and 3 (range, 1 to 9) days after hospitalization. The median incubation period was 11 days, ranging from 1 to 18 days. Most cases were males (57%) with a median age of 20 (15 days to 70 years) years. Ten (71%) cases died during the infection; the rest survived with significant neurological sequelae. In most cases, symptoms started with fever (100%) followed by headache (64%) and vomiting (64%). Subsequently, all patients developed signs of neurological manifestations ranging from incoherent behavior, confusion, increased salivation, neck stiffness, altered level of consciousness to coma. This year's outbreaks exceeded the past eight-year record, and several instances of human-to-human spread indicate the potential to cause larger epidemics in the future. The findings of these outbreak investigations highlight the urgent need for increased efforts in developing vaccines and treatments for Nipah virus infection.

5719

ENVIRONMENTAL SURVEILLANCE TO DETERMINE COVID-19 PREVALENCE IN DISTRICTS IN NORTHERN GHANA WITH NO REPORTED COVID-19 CASES: EVIDENCE TO INFORM PUBLIC HEALTH INTERVENTIONS

Habib Yakubu[1], Christine Moe[1], Stephen Hilton[1], Liu Pengbo[1], Sarah Durry[1], Marlene Wolfe[1], Yuke Wang[1], Mike Osei-Atwenebaona[2], Patrick Kuma Aboagye[3], Dennis Laryea[3], Hannah Ampadu[3], Franklin Asiedu Bekoe[3], Ebenezer Ato Kwamena Senaya[4], Benedict Tuffuor[4], Samuel Armoo[2], Lady Asantewa Adomako[2], Nana Aso Amonoo[2], Mark Akrong[2]

[1]Centre for Global Safe Water, Sanitation and Hygiene, Hubert Department of Public Health, Rollins School of Public Health at Emory University, Atlanta, GA, United States, [2]Council for Scientific and Industrial Research-Water Research Institute, Accra, Ghana, [3]Ghana Health Service, Accra, Ghana, [4]Training, Research and Networking for Development, Accra, Ghana

Environmental surveillance (ES) is a convenient, sensitive, low-cost method to estimate COVID-19 prevalence. Most ES in high-resource countries is implemented in sewered systems. Non-sewered sanitation is common in low-resource settings, and few studies have deployed ES in such environments. We applied ES to detect COVID-19 in two districts with no reported cases of COVID 19 since the beginning of the pandemic to inform public health policy and practice. Mion (pop. 94,930) and Nanumba North (188,680) are rural areas in the Northern region of Ghana. Both localities are sparsely populated. Neither district has a sewerage system, and >70% of the population rely on shared public toilets. Stakeholder analysis was deployed to identify population centers in the community that should be targeted for wastewater or fecal sludge sample collection. Schools (primary, secondary, and college), healthcare facilities, markets, and streams were identified and mapped. From September to November 2022, grab and Moore swab samples were collected daily from septic tanks, pit latrines and surface water. Samples were stored and transported weekly to a central

lab in Accra. Liquid samples were concentrated using Nanotrap particles, RNA extraction, and analyzed by multiplex RT-qPCR. 46 sampling sites were identified, and 194 samples (128 solids samples, 3 Moore swabs, and 63 liquid samples) were collected. 13%, 33.3% and 20% of the liquid, Moore swab, and solids samples tested positive for SARS-COV-2 RNA, respectively. 8.9% of the 78 samples from Mion were positive for SARS-COV-2. Out of the 116 samples from Nanumba North, 24.3% tested positive for SARS-COV-2. Positive samples were from healthcare facilities (6.6%), public latrines (17.7%) and schools (22.5%). No COVID-19 cases were reported from either district during the study period. The Ghana Health Service used the results to develop public health response action plans -including health education and targeted mass vaccination in schools and communities. These findings demonstrate the value of ES to guide the public health response in remote low-resources settings even when clinical cases are not detected.

5720

MEASLES ANTIBODY RESPONSE AND DURATION IN INFANTS WITH HIGH EARLY-LIFE MALARIA EXPOSURE COMPARED WITH LOW MALARIA EXPOSURE

Samantha E. Tulenko[1], Catherine S. Forconi[2], Sylvia Becker-Dreps[1], Jessie K. Edwards[1], John Michael Ong'echa[3], Juliana A. Otieno[4], Hellen Barsosio[3], Peyton Thompson[1], Emily W. Gower[1], Ann M. Moormann[2]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]University of Massachusetts Chan Medical School, Worcester, MA, United States, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]Jaramogi Oginga Odinga Teaching and Referral Hospital, Kisumu, Kenya

Measles continues to cause significant morbidity and mortality globally despite a highly effective vaccine. Immunomodulation caused by high malaria exposure during early-life may impact the response to measles vaccine and the duration of this response. In the present study, we assessed measles antibody levels in a 2-year longitudinal cohort of 166 infants from two sites in Kenya with different levels of malaria transmission. After excluding infants with likely measles exposure prior to vaccination, we categorized measles antibody levels at 10-12 months of age into high/medium/low tertiles and compared the proportion of infants in each tertile between study sites. Using the categories defined by these tertiles at 10-12, 16-18, and 22-24 months of age, we used repeated ordinal logistic regression to compare change between categories over the study duration between study sites. Prior to measles vaccination at nine months of age, 30.6% of infants had measles antibody levels indicative of exposure to the virus. Among infants without pre-vaccine measles exposure, more infants at the low-malaria study site were in the high category of antibody response at 10-12 months compared with infants at the high-malaria study site (42.1% vs. 24.0%, p=0.1). At both sites, more infants moved to the high antibody category throughout the duration of the study, but this change in categories did not differ between study sites. In sum, infants living in the low-malaria community had better vaccine-elicited immunity, on average, than infants in the high-malaria community. The substantial number of infants with likely measles exposure prior to vaccination combined with the increasing antibody levels throughout the duration of the study suggest measles may have been circulating in these populations during the study period. In endemic settings, immunization schedules should take into account gaps in seroprotection prior to vaccination. Further research is needed to understand how to best address potentially lower vaccine response in areas of high malaria transmission.

MACROLIDE RESISTANCE 36 MONTHS AFTER MASS AZITHROMYCIN ADMINISTRATION IN A CLUSTER-RANDOMIZED TRIAL IN NIGER

Ashley Hazel[1], Ahmed M. Arzika[2], Amza Abdou[3], Ramatou Maliki[2], Seth Blumberg[1], Elodie Lebas[1], Travis C. Porco[1], Thomas M. Lietman[1], Jeremy D. Keenan[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]The Carter Center, Niger, Niamey, Niger, [3]Programme Nationale de Santé Oculaire, Niamey, Niger

Mass drug administration (MDA) of azithromycin decreases child mortality but has been shown to select for macrolide and nonmacrolide resistance 24 months after initiation. However, resistance prevalence over time is not well studied. Herein, we evaluate resistance 36 months after initial azithromycin treatment and compare mean prevalence between treatment and control arms. In the MORDOR cluster-randomized trial of mass azithromycin distribution, children ages 1-59 months received either azithromycin (15 villages) or placebo (15 villages) every six months. In total, 423 children were randomly selected to provide nasal swab samples after receiving their 36-month administration of treatment or placebo. Streptococcus pneumoniae isolates from cultured swabs were tested for macrolide and nonmacrolide resistance. The primary outcome was prevalence of macrolide and nonmacrolide resistance for treatment versus placebo groups at 36 months. Of the 423 swabs obtained, 322 grew S. pneumoniae (146/202 in the treatment group and 176/221 in the control group). Macrolide resistance prevalence was 14.6% in treatment villages and 8.9% in control villages (OR=2.0, 95% CI: 0.99-3.97) in a mixed effects regression model. Resistance prevalence of several nonmacrolides did not differ between treatment and controls (p>0.18 for all). Our results suggest that increased exposure to resistance determinants or spillover from treatment villages increased prevalence in control villages. Furthermore, although macrolide resistance prevalence increased significantly from MDA initiation to 24 months, overall resistance at 36 months was only marginally greater than at 24 months, indicating that resistance after twice-yearly azithromycin administration to young children flattens before exponential growth occurs. This longitudinal flattening may not hold for MDA regimens that confer high antibiotic pressure by targeting larger proportions of the population with more frequent dosages, like mass azithromycin for endemic trachoma.

5722

RISK FACTORS FOR COLONIZATION WITH EXTENDED-SPECTRUM CEPHALOSPORIN RESISTANT AND CARBAPENEM RESISTANT ENTEROBACTERALES AMONG HOSPITALIZED PATIENTS IN BANGLADESH: ANTIBIOTIC RESISTANCE IN COMMUNITIES AND HOSPITALS -ARCH-STUDY

Syeda Mah-E-Muneer[1], **Fahmida Chowdhury**[1], Kamal Hossain[1], Rachel M. Smith[2], Ashley R. Styczynski[2]

[1]icddr,b, Dhaka, Bangladesh, [2]CDC, Atlanta, GA, United States

Understanding risk factors for colonization with antimicrobial resistant (AMR) organisms is critical for implementing effective prevention strategies to reduce transmission and risk for developing invasive infections. During Apr-Oct 2019, we conducted a period prevalence study in three hospitals in Dhaka city during which we continuously enrolled patients using simple random sampling. We collected stool samples from hospitalized adult patients to detect extended-spectrum cephalosporin resistant (ESCrE) and carbapenem resistant (CRE) Enterobacterales. We recorded information on patient characteristics, admission wards, antibiotic use, duration of hospitalization at enrollment, and healthcare exposures. Based on a conceptual framework, we used multivariate logistic regression models adjusting for potential confounders to identify the risk factors for colonization. Of 743 enrolled patients, the median age was 40 (IQR:30-55) years, 54% were male, and 44% had underlying chronic illnesses. Median time between hospital admission and patient enrollment was 3 days (IQR:

2 - 6 days) with stool typically collected the following day. Among enrolled patients, 592 (82%) were colonized with ESCrE and 267 (37%) with CRE. Risk factors for ESCrE colonization were stay in a surgical ward compared with a medicine ward (aOR 2.1, CI: 1.3-3.2) and hospitalization for 3-7 days (aOR 1.9, 1.2-3.0). Risk factors for CRE colonization included admission from another healthcare facility (aOR 3.1, 1.5-6.4); stay in a surgical ward (aOR 1.7, 1.1-2.5); hospitalization for 3-7 days (aOR 1.7, 1.2-2.4) and >=7 days (aOR 2.9, 1.8-4.6); invasive procedures (aOR 2.4, 1.3-4.4); urinary catheter use (aOR 2.1, 1.1-4.2); and antibiotic administration in the last 14 days (aOR 2.9, 2.0-4.0). In conclusion, longer hospital stays and more invasive procedures were associated with increased risk for colonization with AMR organisms. These findings emphasize the need for enhanced infection prevention and control efforts to mitigate the transmission of AMR organisms in Bangladeshi hospitals.

5723

MOLECULAR EPIDEMIOLOGY OF ASYMPTOMATIC CRYPTOSPORIDIUM, GIARDIA, AND ENTAMOEBA INFECTIONS: THREATS TO THE HEALTH OF NIGERIAN CHILDREN?

Oluwaremilekun Grace Ajakaye[1], Egie Enabulele[2], Amana Onekutu[3], Ehizogie Adeyemi[4], Emmanuel Effanga[5], Joshua Balogun[6], Muhammad Ali[7], Samuel Dahal[8], Timothy Auta[9], Umoru Askira[10], Victor Njom[11], Michael Grigg[12]

[1]Adekunle Ajasin University, Akungba Akoko, Nigeria, [2]Texas Biomedical Research Institute, San Antonio, TX, United States, [3]Federal University of Agriculture, Makurdi, Nigeria, [4]University of Benin Teaching Hospital, Benin, Nigeria, [5]University of Calabar, Calabar, Nigeria, [6]Federal University Dutse, Dutse, Nigeria, [7]Kano state Polytechnic, Kano, Nigeria, [8]Jos University Teaching Hospital, Jos, Nigeria, [9]Federal University Dutsin-Ma, Dutsin-Ma, Nigeria, [10]University of Maiduguri Teaching Hospital, Maiduguri, Nigeria, [11]Enugu State University of Science and Technology, Enugu, Nigeria, [12]National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, United States

Intestinal parasitic infections have significant impacts on the health of children. Apart from causing diarrheal diseases, Cryptosporidium and Giardia infections have negative impacts on children's growth and cognitive development and may result in death in immunocompromised individuals. At the national level, there is a scarcity of information on the molecular epidemiology of Cryptosporidium, Giardia and Entamoeba infections in children in Nigeria. As a result, we present for the first time in Nigeria a nationwide assessment of the prevalence, associated risk factors, and genetic profiles of Cryptosporidium, Giardia and Entamoeba species in children aged 10 and below. In total, 985 stool samples were collected from ten states, along with an epidemiological questionnaire. We used real-time PCR and DNA sequencing to detect and genotype the three enteric parasites in stool samples. A variety of statistical and bioinformatic tools were used to analyze the data. The most common parasite found in this study was Giardia sp. (77.4%), followed by Cryptosporidium (19.5%) and Entamoeba (12.3%). Coinfections with two or all three parasites were found in 10% of the children in this study, with Cryptosporidium + Entamoeba coinfection being the least common. Several socioeconomic factors, including toilet type, drinking water source, livestock rearing, and hygiene habits, were identified as risk factors for infection with one or more of the parasites.The main circulating species were identified through genetic analysis as C. parvum, Giardia Assemblage A2 and B, Entamoeba histolytica and Entamoeba dispar. Regardless of the presence or absence of symptoms, our study found a high burden of intestinal parasitic infection in children in Nigeria which was linked to poor hygiene and poverty-related factors.

A CONTINENTAL PICTURE OF SLEEPING SICKNESS: USING MODELS FROM THE DRC TO ESTIMATE GLOBAL GAMBIENSE HUMAN AFRICAN TRYPANOSOMIASIS BURDEN AND PROJECTED RESOURCE USE AND COST UNDER VARIOUS CONTROL STRATEGIES

Samuel A. Sutherland[1], Ronald E. Crump[1], Christopher N. Davis[1], Ching-I Huang[1], Marina Antillon[2], Simon E.F. Spencer[3], Paul E. Brown[1], Emily H. Crowley[1], Erick Mwamba Miaka[4], Kat S. Rock[1]

[1]SBIDER, University of Warwick, Coventry, United Kingdom, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]Department of Statistics, University of Warwick, Coventry, United Kingdom, [4]Programme National de Lutte contre la Trypanosomiase Humaine Africaine (PNLTHA), Kinshasa, Congo, Democratic Republic of the

Gambiense Human African Trypanosomiasis (gHAT, sleeping sickness) affects several countries across central and western Africa, spanning a diverse range of geographies and epidemiology. In 2019-2020, 70% of all reported gHAT cases were recorded in the Democratic Republic of the Congo (DRC). We have previously fitted a dynamic transmission model to historical data in 168 endemic or formerly endemic health zones of the DRC, across a range of geographies and levels of case reporting from no cases in the last decade to thousands. In this study, we produce a picture of the resources required for gHAT control across the whole continent. We classified the health zones of the DRC for which we have enough data to fit the transmission model by their risk level according to the WHO definitions and then combine them to produce aggregated fits for each risk level. We then used these aggregated fits in combination with WHO estimates of the population living at each level of risk to produce projections across the whole continent. A set of possible interventions were then considered based on estimates of local capacity for screening and geographical suitability for vector control. We made projections under multiple strategies and predicted the disease burden and probability of elimination over time as well as estimating resource use and cost. These projections were used to produce a global health economic analysis under a modified, previously published, version of the net monetary benefit framework. Each strategy's cost-effectiveness is considered with respect to disease burden and its effect on probability of elimination. We also forecast the number of drug doses, diagnostic tests, and tiny targets needed under each strategy and in each country to reach elimination. These projections are made available in a graphical user interface to allow them to be explored and visualised easily.

5725

CHAGATYPER: DEVELOPMENT OF A RAPID RESPONSE, SEMI-AUTOMATED, HIGH-RESOLUTION GENOTYPING PLATFORM FOR CHAGAS DISEASE

Natalie Elkheir[1], Clara Gyhrs[2], Debbie Nolder[1], Peter L. Chiodini[1], David AJ Moore[1], Martin Llewellyn[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom

Approximately 30% of Trypanosoma cruzi seropositive individuals develop end-organ cardiovascular and/or gastrointestinal pathology, so-called chronic determinate Chagas disease. The determinants of progression in Chagas disease are not clear. Parasite genetics - at the DTU or sub-DTU level - has long been thought to play a role. However, the difficulty in isolating and genotyping the parasite directly from patients has frustrated efforts to define the link with pathology. Through a collaboration between the University of Glasgow's School of Biodiversity, One Health and Veterinary Medicine (SBOHVM), the Diagnostic Parasitology Laboratory at the London School of Hygiene & Tropical Medicine and the UK Chagas Hub, we aim to establish a prototype clinical genotyping platform for Chagas disease. The UK Chagas Hub has detected and linked into care 100 new cases of Chagas disease in the last year, with screening and active case-finding initiatives ongoing. Over a quarter (27%) of these patients confirmed to be seropositive were also T. cruzi PCR positive. A genome-wide AmpSeq approach to provide high-resolution

genotypes directly from biological samples has been developed. This AmpSeq approach has been successfully piloted with two peripheral blood samples from newly-diagnosed (chronic indeterminate) cases of Chagas disease detected through UK Chagas Hub screening. We are currently generating an AmpSeq reference strain database, with 100 reference strains covering different major genetic lineages (DTUs) and geographic localities. The reference database will support a user-friendly, interactive, online visualisation tool through which PCR amplicons from clinical samples can be compared. The platform will be tested by 100 further UK Chagas Hub clinical samples (data from PCR amplicons sequenced by a third-party added to the online genotyping platform). A semi-automated, high-resolution genotyping platform for Chagas disease will allow the combination of genotype and clinical phenotype information from large cohorts of patients, which can inform our understanding of the determinants of Chagas disease progression.

5726

MOLECULAR-BASED EVIDENCE OF TRANSMISSION OF ATYPICAL TRYPANOSOMIASIS (A-HAT) IN HUMANS IN SELECTED COMMUNITIES IN THE SUHUM MUNICIPALITY OF GHANA

Kofi Agyapong Addo

Akenten Appiah-Menka University of Skills Training and Entrepreneurial Development, Kumasi, Ghana

Human African Trypanosomiasis is transmitted by only two subspecies of Trypanosoma (Trypanosoma brucei gambiense and T. brucei rhodesiense) in sub-Saharan Africa. However, case reports of some Trypanosomes (T. congolense, T. evansi, T. brucei brucei, and Trypanosoma vivax) thought to be natural parasites only to animals have been reported to cause “atypical Human African Trypanosomiasis” (a-HAT). The study therefore aimed at providing molecular-based evidence of the transmission of atypical trypanosomiasis in humans in selected communities in the Suhum Municipality of Ghana. A cross-sectional community-based study design was employed to sample venous blood from 240 human participants. Demographics and risk assessment data from participants and polymerase chain reaction (PCR) assays were performed, using trypanosome internal transcribed spacer 1 (ITS1) generic primers from extracted DNA. PCR products were purified and subcloned into pJET1.2/blunt plasmid. Single clones were checked by ITS1 inner primers (colony PCR). Positive clones were cultured overnight at 37°C at 220rpm in 5mL LB medium with 100µg/mL Ampicillin. The cultures were purified and sent to MicroSynth Labs. Sequences were analyzed and aligned with Geneious Pro 5.5.9. The overall prevalence of trypanosome infection was 15.8% (39/240). Age categories 11-20yr and 41-50yr recorded high prevalence of 21.6% and 22.2% respectively. Infection distribution among males and females was 18.0% and 13.6% (X2=0.9001 p>0.05). The highest prevalence of 19.2% a-HAT was recorded at Zorrh followed by Nkantekwan (17.9%) while no evidence of infection at Santramor No.1 was observed. Trypanosome parasites found in this study area were T. evansi, T. congolense, T. vivax and T. simiae. No association was established between tsetse fly bite and Trypanosomiasis (X2 =1.344 p> 0.05). There is a high prevalence of atypical human trypanosomiasis(a-HAT) in the study area. This underscores the need to investigate the impact of animal parasites on human health in order to institute measures that can help prevent the spread of these parasites

5727

LEISHMANIA INFANTUM VERTICAL TRANSMISSION IN NATURALLY INFECTED DOGS FROM AN ENDEMIC REGION OF BRAZIL

Diogo Valadares[1], Flavio Coutinho[1], Maria S.M. Amarante[1], Ana Maria R. Oliveira[1], Damila K. Melo[1], Romeika K.R Lima[2], Marcela Vidal[2], Grant D. Brown[3], Jacob J. Oleson[3], Mary E. Wilson[3], Christine A. Petersen[3], Selma MB Jeronimo[1]

[1]IMT - UFRN, Natal, Brazil, [2]Canis&Catus, Natal, Brazil, [3]University of Iowa, Iowa City, IA, United States

Visceral leishmaniasis (VL) due to Leishmania infantum is a parasitic illness reported in Europe and Latin America. Dogs are considered the main parasitic reservoir in periurban areas of Brazil. Leishmania transmission in these regions has been traditionally considered to be vector-borne. Although vertical transmission of Leishmania has been shown to have a major impact in maintaining a population of infected dogs, it is not considered yet in control strategies for Brazil. The aim for this study was to evaluate whether and how frequently vertical transmission of Leishmania occurs in a highly endemic setting of Natal, Brazil. We hypothesized that transplacental transmission of Leishmania parasites in Natal may occur at a similar frequency to that observed in dogs in non-endemic regions. To address this, a total of 7 naturally Leishmania-infected pregnant females and their resultant pups (n=48) were recruited and divided into two groups. The first was a cross sectional study to assess presence of parasites in tissues of (aborted) puppies (n=30) from euthanized female dogs (n=4) and the second a prospective evaluation of 3 liters (n= 18), born at a sandfly free facility, to evaluate parasitemia and anti-Leishmania serology for 12 months. In the first study, we found disseminated Leishmania infection in feti, by RT-qPCR, from four pregnant dogs via L. infantum kDNA (89.28%) and detected splenic parasite antigen via IHC in 85.7% of feti. All dogs (100%) from the prospective cohort study were Leishmania positive by both soluble parasite antigen ELISA and parasitemia. Positive correlation between parasitism in umbilical cord blood and in the pup over time supported not only mechanistic evidence of transmission of parasites through umbilical vessels, but also suggests the use of this tissue as a clinical tool to predict Leishmania vertical transmission. These findings support the hypothesis that the incidence of vertical transmission of Leishmania infantum parasites in dogs in endemic areas of Brazil is high and demonstrates the need for novel strategies to control canine VL, including regions where human VL is also endemic.

5728

CLINICAL AND METAGENOMIC CHARACTERIZATION OF CEREBRAL TOXOPLASMOSIS IN THE PERUVIAN AMAZON.

Hannah E. Steinberg[1], Prashanth S. Ramachandran[2], Andrea Diestra[3], Lynn Pinchi[4], Cusi Ferradas[5], Daniela E. Kirwan[6], Monica M. Diaz[7], Micheal Sciaudone[8], Annie Wapniarski[2], Kelsey C. Zorn[2], Maritza Calderón[3], Lilia Cabrera[4], Viviana Pinedo Cancino[9], Micheal Wilson[2], Cesar Ramal[10], Robert H. Gilman[11], Natalie M. Bowman[7]

[1]University of Illinois, Chicago, Chicago, IL, United States, [2]UCSF, San Francisco, CA, United States, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]AB Prisma, Lima, Peru, [5]University of California Davis, Davis, CA, United States, [6]St George's, University of London, London, United Kingdom, [7]University of North Carolina, Chapel Hill, NC, United States, [8]Tulane University, New Orleans, LA, United States, [9]Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [10]Hospital Regional de Loreto, Iquitos, Peru, [11]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Neurological opportunistic infections are a significant cause of morbidity and mortality in people living with HIV (PLHIV). We conducted a study of 140 PLHIV with acute neurological symptoms from Iquitos, Peru. Participants were evaluated for cerebral toxoplasmosis. Poisson regression with robust variance was used to assess differences between patient with and without cerebral toxoplasmosis. A subset of samples were evaluated by metagenomic next-generation sequencing (mNGS) of cerebrospinal fluid (CSF) for comparison with standard diagnostic techniques and identification

of additional diagnoses. 27 participants were diagnosed with cerebral toxoplasmosis by CSF qPCR. Compared to participants without cerebral toxoplasmosis, abnormal Glasgow coma score (p=0.05), unilateral focal motor signs (p=0.01), positive Babinski (p=0.01), and multiple intracranial lesions on head computed tomography (CT) (p=0.002) were associated with cerebral toxoplasmosis. mNGS identified 7 cases of cerebral toxoplasmosis, 7 cases of cryptococcal meningitis, and other possible cases of TB(n=5), hepatitis B (n=1), and pegivirus (n=1). CSF mNGS had a positive percent agreement of 71% and a negative percent agreement of 91% with qPCR for T. gondii. An infection was definitively diagnosed by any method for only 35% of participants, demonstrating the challenges of diagnosing neurological opportunistic infections in this population and highlighting the need for broader, more sensitive diagnostic tests for CNS infections.

5729

RISK FACTORS FOR MOTHER-TO-CHILD TRANSMISSION OF TRYPANOSOMA CRUZI AND HEPATITIS B IN THE CROSS-BORDER AREA OF ARGENTINA AND PARAGUAY

Yoshiko Takahashi[1], Susana Avila[2], Silvia Correa[3], Karina Cardone[2], Mariana Fernández[2], Favio Crudo[2], Miho Sato[1], Hirotsugu Aiga[1], Kenji Hirayama[1], Maria V. Periago[4]

[1]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, [2]Fundación Mundo Sano, Buenos Aires, Argentina, [3]Universidad Nacional de Salta, Salta, Argentina, [4]CONICET/Fundación Mundo Sano, Buenos Aires, Argentina

Mother-to-child transmission (MTCT) of Trypanosoma cruzi and hepatitis B virus (HBV) contribute to increased morbidity and disability in Latin America and the Caribbean region. The framework for eliminating MTCT of HIV, syphilis, hepatitis B, and Chagas (EMTCT Plus) has been implemented in the region since 2018 by Mundo Sano in collaboration with several private-public institutions. This study aims to: (i) identify the risk factors for MTCT of T. cruzi and HBV; and (ii) evaluate the effectiveness of the implementation of the framework in the cross-border area of Argentina and Paraguay. Data on T. cruzi and HBV infection among pregnant women and their infants was collected from the antenatal care registries during June 2018 to December 2022. MTCT rates and access to the screening were examined. Bivariate and multivariate analyses were used to explore associations between the infections and socio-demographic factors. Additionally, we conducted 34 Key Informant Interviews (KIIs) for both implementers and service recipients to identify barriers to and promoters for access to screening and treatment of these infections. Finally, we integrated the quantitative and qualitative data using the Consolidated Framework for Implementation Research (CFIR) to evaluate the effectiveness of the intervention. Our preliminary results show approximately 1,493 mothers accessed antenatal care screening for these two infections. The prevalence of T. cruzi among mothers and newborns was estimated at 6.36% (CI95% 5.12-7.60) and 15.9% (CI95%: 1.90-45.44), respectively. However, the screening coverage for newborns who born to the T. cruzi seropositive mothers was only 57.0%. Treatment coverage for newborns was 100%, but post-partum treatment coverage among mothers was only 35.8%. Potential identified barriers were geographical distance to health care services, cultural beliefs, and lack of knowledge about the diseases in the communities. Our findings will be shared with high-level policymakers in the two countries and may be used to improve the implementation of T.cruzi and HBV programs in the region.

5730

ETIOLOGY, GAPS, AND CHALLENGES IN THE DIAGNOSIS AND MANAGEMENT OF SEPSIS AMONG UNDER-FIVES ENROLLED IN THE KENYA CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE NETWORK (CHAMPS) PROGRAM

Harun Odhiambo Owuor[1], Dickens Onyango[2], Richard Omore[1], Beth Tippet Barr[3], Victor Akelo[4]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Kisumu County Department of Health, Kisumu, Kenya, [3]Nyanja Health Research Institute, Malawi, Malawi, [4]Center for Disease Control, Atlanta, GA, United States

Sepsis remains the third leading cause of death in children under five years globally, despite reduced mortality through improved treatment. Diagnosis and clinical management continue to pose a challenge in developing countries. Child Health and Mortality Prevention Surveillance (CHAMPS) is a multi-country surveillance program that systematically identifies causes of under-five mortality from defined catchment areas in seven countries in sub-Saharan Africa and South Asia. Here, we describe the etiology, gaps and challenges in diagnosis and treatment of sepsis in children under 5 years of age enrolled in CHAMPS-Kenya. Causes of death (COD) were determined by a panel of experts using data from post-mortem investigations conducted using minimally invasive tissue specimen testing, clinical records, and verbal autopsy. Between May 2017 and Dec 2022, 697 children below 5 years had their COD determined. Of these, (132) had sepsis in the causal chain leading to death. Of those, 53 (40.2%) were community-based deaths and 48(36.4%) were neonates, 50 (37.9%) were infants, 32 (24.2%) were children above one year of age and 2(1.5%) were stillbirths. The main causative agents of sepsis were Klebsiella pneumonae (42, 34.1%), Escherichia coli (22, 17.9%) and Streptococcus pneumonae (17, 13.8%) respectively while 32 (24.2%) cases had multi pathogen sepsis. One third of hospitalized cases died within the first 24 hours admission; admission diagnoses included shock, severe dehydration, and severe gastroenteritis in 40% of cases. Ninety-five percent of hospitalized cases were not diagnosed with sepsis before death. Blood chemistries were performed in 30% of all hospitalized cases, but none of the cases had peripheral blood cultures or blood gases performed. Sepsis is common among CHAMPS cases in Kenya, with significant antemortem disparities in diagnosis and clinical management of identified cases. Given the complexity of sepsis diagnosis, especially in under-five, maternal health education on danger signs, a high index of clinical suspicion, and training on optimal clinical management could reduce sepsis-related deaths.

GENOMIC CHARACTERIZATION OF EXTRAINTESTINAL PATHOGENIC ESCHERICHIA COLI ISOLATED FROM STILLBIRTHS AND EARLY NEONATAL DEATHS: AN OBSERVATION FROM CHAMPS BANGLADESH

Muntasir Alam[1], Md. Fakhruddin[1], Md Saiful Islam[1], Afruna Rahman[1], Arpita Shyama Deb[1], Nairita Ahsan Faruqui[1], Mohammad Zahid Hossain[1], Shams El Arifeen[1], Emily S. Gurley[2], Mustafizur Rahman[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Extraintestinal pathogenic Escherichia coli (ExPEC) are non-diarrheagenic E. coli (EC) known to cause urinary tract infection, sepsis and neonatal meningitis. Presence of specific virulence genes aids to this characterization. Here we aim to use whole genome sequencing (WGS) to characterize ExPEC isolated from postmortem blood collected from stillbirths and neonates enrolled in the Child Health and Mortality Prevention Surveillance (CHAMPS) project in Bangladesh. CHAMPS uses laboratory diagnosis, clinical, demographic and epidemiological data to determine the causes of stillbirths and under-5 deaths. From Aug 2017 to Dec 2021, blood culture data from 357 post-mortem stillbirths (n = 173) and neonates (n = 184) were analyzed. WGS was performed and analyzed for sequence typing, virulence and antimicrobial resistance genes. EC was detected from

3.9% (14/357) cases including macerated stillbirths (n = 10) and neonates (n = 4). EC was not attributed to be in the causal chain after review by a panel of experts. However, WGS identified ExPEC associated virulence genes from half (7/14) of the EC isolates (5 stillbirths and 2 neonates). All ExPEC isolates belong to different sequence type and serotype. Six (6/7) ExPECs were closely related to uropathogenic EC and harbored virulence genes such as P fimbriae (papA, papC), S fimbriae (sfaD, sfaS), K1 capsule (kpsMII, neuC), cytotoxic necrotizing factor (cnf-1), as well as different siderophore systems (fyuA, iroN) and toxins (clbB, tcpC) which help ExPECs to colonize and infect organs other than the gastrointestinal tract of the fetus. Genomic investigation identified 5 of these ExPECs as multi drug resistant and also extended-spectrum β-lactamase (ESBL)-producers (carrying blaCTX-M-15). However, these were sensitive to carbapenem antibiotics. Presence of virulence features and close relatedness to uropathogenic EC indicated the potential that these organisms were transmitted from mother to the fetus, resulting in negative outcomes. Diagnosis of symptomatic or asymptomatic urinary tract infection in pregnant women may reduce the chance of mother to child transmission of ExPECs.

5732

URECA-LAMP: RAPID, CHEAP AND EFFECTIVE POINT-OF-CARE SCREENING OF CEPHALOSPORIN AND CARBAPENEM RESISTANCE FOR LOW MIDDLE-INCOME COUNTRIES

Ricardo Castellanos, Hitendra Kumar, **Ryan Chaffee**, Yoonjung Lee, Gisele Peirano, Johann Pitout, Keekyoung Kim, Dylan R. Pillai
University of Calgary, Calgary, AB, Canada

Gram-negative bacteria are common causative agents of urinary tract infections (UTIs) worlwide. These bacteria frequently carry genes encoding extended-spectrum beta-lactamases (ESBL) and/or carbapenemases. UTI-screening for these genes with point-of-care testing (POCT) can aid in guiding empirical treatment and reduce antimicrobial resistance (AMR). The novel Urine ESBL and Carbapenemase (URECA) panel is a 7-tube strip. Each well contains primers to detect ESBLs CTX-M-1-group and CTX-M-9-group and carbapenemases OXA-23, OXA-48-like, OXA-50, NDM and VIM. The White Lotus is a novel LAMP-POCT device manufactured by our group. It is portable, battery-operated, low cost and smart phone operable. The aim of this study was to validate the URECA-LAMP panel for rapid screening of ESBL- and carbapenemase-producing bacteria. To this end, a sample set of 70 bacterial strains (10 positive controls per target) was obtained from the well-defined SMART and INFORM bacterial collections. Previous WGS characterization of the strains was used as gold-standard for comparison against URECA-LAMP results. DNA template was prepared by boiling a single bacterial colony from each sample in 0.5 mL of nuclease-free water for 10 minutes. 20 uL of boiled sample was added to each of the wells in URECA panel. 2.5 uL of hydroxy naphthol blue was added to each well for visual detection. Positive results were defined as fluorescence-emitting tubes under blue-led light. After screening the complete sample set, comparison between URECA-LAMP and previous WGS results showed 100% agreement of positive and negative results for each gene. We conclude URECA-LAMP is suitable for detection of ESBLs/carbapenemases in bacteria from UTIs. Our results indicate its feasibility for POC screening of human urine specimens. The lower production cost of the White Lotus instrument makes URECA-LAMP attractive for implementation in low middle-income countries.

5733

DEVELOPMENT OF A KLEBSIELLA PNEUMONIAE NEONATAL SEPSIS MOUSE MODEL TO EVALUATE VACCINES

Jernelle C. Miller, Scott C. Baliban, Alan S. Cross, Sharon M. Tennant
Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, Baltimore, MD, United States

Klebsiella pneumoniae is a major cause of neonatal sepsis in low-to-middle income countries. With the proportion of multidrug-resistant K. pneumoniae strains increasing globally and the lack of novel antibiotics in the pipeline, vaccination to prevent these infections is an attractive strategy. Several K. pneumoniae vaccines are currently in development, however, there are no animal models of K. pneumoniae-related neonatal sepsis that could be used to evaluate vaccine efficacy. Our goal is to identify a model which produces a 50% lethal dose (LD50) of ~106 CFU of 2- to 3-day-old animals and which shows an age-dependent susceptibility to infection. We have previously evaluated species (mice vs. rats), 3 mouse strains, 3 routes of infection, and 5 K. pneumoniae strains. We found that peroral (PO) infection of 2- to 3-day-old C57BL/6 mice with K. pneumoniae B5055 produced mortality. Here we describe characterization of this model in terms of the LD50 and age-dependent susceptibility to infection. We determined the PO LD50 of K. pneumoniae B5055 to be 8.5 x 106 CFU in 2-day-old C57BL/6 mice. We also tested PO infection with 108 CFU and 109 CFU, demonstrating these inocula could reliably produce 77-100% mortality in 2- to 3-day-old C57BL/6 mice (n = 4 litters of 5-9 mice per litter; 109 CFU: 3.1% ± 6.3% survival, mean ± standard deviation; 108 CFU: 23.5% ± 22.3% survival). Furthermore, C57BL/6 mice demonstrated an age-dependent susceptibility to infection, where 2- and 5-day-old pups exhibited 100% (7/7) and 50% (4/8) mortality following PO exposure to K. pneumoniae B5055, respectively. K. pneumoniae was found in the blood, spleen, liver, and intestines of infected neonates. In contrast, 30- and 60-day-old C57BL/6 mice exhibited low susceptibility to infection with K. pneumoniae B5055 administered PO (1/10 and 1/10, respectively) and low bacterial colonization (1/10 and 0/10, respectively). We are currently evaluating 7-, 10- and 15-day-old mice. In conclusion, we have developed a neonatal sepsis model which consists of PO infection of neonatal C57BL/6 mice with K. pneumoniae B5055. We continue to characterize this model.

5734

FIRST REPORT OF OXA-181-PRODUCING ENTEROBACTERALES IN LATIN AMERICA

Diego Cuicapuza[1], Guillermo Salvatierra[1], Alejandra Dávila-Barclay[1], Luis Alvarado[2], Norah Tocasca[3], Daniel Aguilar[3], Juan Carlos Gómez-de-la-Torre[2], Andres G. Lescano[4], Pablo Tsukayama[1], Jesús Tamariz[5]
[1]Laboratorio de Genómica Microbiana, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Laboratorio Clínico Roe, Lima, Peru, [3]Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru, [4]Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Laboratorio de Resistencia Antibiótica e Inmunopatología, Universidad Peruana Cayetano Heredia, Lima, Peru

Carbapenemase-producing Enterobacteriaceae (CPE) infections are a growing threat contributing to the global burden of antimicrobial resistance (AMR). Although carbapenemase enzymes KPC, NDM and IMP are the most common enzymes worldwide, β-lactamase type OXA-48-like(oxacillinases) are on the rise. The blaOXA-181(a variant of OXA-48) enzymes show a high level of hydrolytic activity against penicillins and a low level of hydrolysis of carbapenems, with a strong preference for imipenem, which is challenging for laboratory diagnosis and may misguide treatment strategies. CPE blaOXA-181 has been reported in human, animal and environmental samples, but has not yet been reported in Latin America. We characterized five CPE clinical isolates from two healthcare facilities in Lima, Peru. The isolates were identified as Klebsiella pneumoniae (n=3),

Citrobacter portucalensis, and Escherichia coli, all presenting multidrug-resistant phenotypes. Illumina sequencing revealed the presence of the blaOXA-181 gene as the only carbapenemase in all isolates. Genes associated with resistance to aminoglycosides, quinolones, amphenicols, fosfomycins, macrolides, tetracyclines, sulfonamides, and trimethoprim were also found.The plasmid group IncX3 was identified in all genomes in a truncated Tn6361 transposon flanked by ΔIS26 insertion sequences. The qnrS1 gene was found downstream of blaOXA-181, conferring fluoroquinolone resistance to all isolates. The emergence of blaOXA-181 in association with the qnrS1 gene in IncX3-type plasmids may represent the primary vector for the spread of blaOXA-181 in Latin America. Genomic surveillance of atypical AMR patterns in clinical and non-clinical isolates is needed to elucidate the transmission of this CPE genotype, as routine clinical laboratory diagnoses fail to detect these new OXA variants.

5735

THE RELATIONSHIP BETWEEN CO-MORBID MALNUTRITION AND DIARRHEAL ILLNESS AMONG HOSPITALIZED TANZANIAN CHILDREN UNDER FIVE YEARS OF AGE

Stephanie A. Brennhofer[1], Sifaeli Katengu[2], Godfrey Guga[2], Yotham Z. Michaeli[2], Miriam Temu[2], Frederick Habiye[2], James A. Platts-Mills[1], Estomih R. Mduma[2], Elizabeth T. Rogawski McQuade[3]

[1]University of Virginia, Charlottesville, VA, United States, [2]Haydom Lutheran Hospital, Haydom, Tanzania, United Republic of, [3]Emory University, Atlanta, GA, United States

There is a bidirectional association between malnutrition and diarrheal illness wherein malnutrition increases the risk, frequency, and duration of diarrhea while diarrhea further exacerbates malnutrition through nutrient depletion. We analyzed preliminary data on 120 (females: n=47, 39.1%; mean age: 14 ± 10 months) children enrolled in the Diarrhea Etiology and Malnutrition study who were hospitalized with diarrhea at Haydom Lutheran Hospital in Haydom, Tanzania from July 2022 to February 2023. There were 25 (20.8%) severe/moderate malnourished children based on doctor report. An infectious etiology was identified for 70/94 (74.5%) children infected (Ct < 30) with at least one of the top 10 pathogenic causes of diarrhea found in the MAL-ED study (n=28 bacterial and viral, n=22 bacterial, n=19 viral, n=1 parasitic). Log binomial and linear regression analyses adjusted for sex were used to determine the relationship between malnutrition and diarrhea etiology, length of stay (LOS), and respiratory illnesses. There were no associations between malnutrition and identification of an infectious etiology of diarrhea (RR: 0.87; 95% CI: 0.63, 1.21). Children with malnutrition were not more likely to have a bacterial etiology (RR: 0.97, 95% CI: 0.61, 1.53) or viral etiology (RR: 0.51, 95% CI: 0.25, 1.03). Malnourished children with diarrheal illness had significantly longer hospital stays (LOS difference: 8.23 days; 95% CI: 5.26-11.19 days) than children who were not malnourished. No differences in LOS between bacterial and non-bacterial diarrhea were observed (LOS difference: 0.93 days; 95% CI: -2.33, 4.19). Malnourished children were more likely to have co-morbid respiratory symptoms (RR: 1.47; 95% CI: 0.89, 2.46) compared to children who were not malnourished. In conclusion, although malnourished children were not at greater risk for specific diarrhea etiologies, they were more likely to have longer hospitalizations. These data suggest malnutrition may contribute to poor outcomes of hospitalized diarrhea independent of diarrhea etiology.

ETIOPATHOLOGY OF STUNTING: INFANT GUT CHARACTERIZATION AND MICROBIAL INFLUX ROUTES IN A MOTHER-INFANT COHORT IN CENTRAL-AFRICA

Violeta Moya-Alvarez[1], Amine Ghozlane[2], Pascale Vonaesch[3], Daniel Mad-Bondo[4], Bertrand Kongoma[4], Serge Djorie[5], Philippe Sansonetti[2]

[1]Institut de Recherche pour le Développement, Paris, France, [2]Institut Pasteur, Paris, France, [3]Université de Lausanne, Lausanne, Switzerland, [4]Maternité Henri Izamo, Bangui, Central African Republic, [5]Institut Pasteur de Bangui, Bangui, Central African Republic

Background : Environmental enteric dysfunction (EED) is an enigmatic disease of the small intestine intimately associated with child undernutrition, a pressing global health problem with over 149 million children affected globally. The etiopathology of EDD has remained elusive for decades. Recent evidence showed that stunting was associated with small intestinal bacterial overgrowth dominated by bacteria that normally reside in the oropharyngeal cavity in children 2-5 years. However, evidence is limited on how the oropharyngeal cavity and the gut are colonized in the stages preceding the appearance of stunting in a context of a high burden of stunting and a highly microbial polluted environment. Methods : We followed a cohort of 50 infants from birth until 6 months of life in Bangui (Central-African Republic). We performed metagenomic analyses of oral and stool microbiota at birth, and at 1, 4, 11, 18, and 25 weeks. We also analyzed breastmilk microbiota starting at 1 week. We gathered complete socio-economic and clinical data, anthropometric measures and 24-hour recalls and food-consumption questionnaires for diet assessment at each visit. Results : Stunting was significantly associated with stool microbiota of the infants at 6 months (P value of the Permanova = 0.04). The relative abundance of Rothia SGB16985, Streptococcus parasanguinis, and Veillonella dispar was significantly higher among non-stunted infants in both oral and stool samples. Even if there were no significant differences in the breastmilk microbiota depending on stunting status of the infant, 6/10 of the species with the highest relative abundance in breastmilk (Rothia SGB16985, Streptococcus thermophilus, Streptococcus peroris, Streptococcus pneumoniae, Staphylococcus hominis, and Streptococcus salivarius) were significantly associated with stunting in oral and stool samples. Conclusion : The ectopic colonization of oral bacteria in the gut occured also in the absence of stunting. The role of the breastmilk microbiota should be further investigated in the context of stunting and a highly microbial polluted environment.

5737

DISCOVERY OF A SMALL MOLECULE THAT MIMICS A UNIQUE ZIKA-NEUTRALIZING EPITOPE FROM A LARGE LIBRARY OF RANDOM MOLECULAR SHAPES

Priscila Mayrelle Da Silva Castanha[1], Patrick J. McEnaney[2], Yongseok Park[1], Anthea Bouwer[1], Elton Chaves[3], Roberto Lins[3], Nicholas G. Paciaroni[4], Paige Dickson[2], Graham Carlson[4], Marli T. Cordeiro[3], Tereza Magalhães[5], Jodi Craigo[1], Ernesto T A Marques Jr.[1], Thomas Kodadek[2], Donald S. Burke[1]

[1]University of Pittsburgh, Pittsburgh, PA, United States, [2]The Herbert Wertheim UF Scripps Institute for Biomedical Innovation and Technology, Jupiter, FL, United States, [3]Aggeu Magalhaes Institute, Oswaldo Cruz Foundation, Recife, Brazil, [4]Deluge Biotechnologies, Jupiter, FL, United States, [5]Department of Entomology, Texas A&M University, College Station, TX, United States

Antigenic similarities between Zika virus and other flaviviruses pose challenges to the development of virus-specific diagnostic tools and effective vaccines. We screened a DNA-encoded one-bead-one-compound combinatorial library of 508,032 synthetic, non-natural oligomers, for compounds that mimic ZIKV-specific epitopes. High-throughput FACS-based screening was used to select molecules that bound IgG from ZIKV-immune but not from dengue-immune sera. Deep sequencing of the encoding tags on beads that retained high levels of antibodies to ZIKV-immune serum and clustering analysis of structurally homologous

hits identified 40 candidate molecular structures. A lead candidate small molecule "CZV1-1" was selected that correctly identifies serum specimens from Zika-experienced patients with high sensitivity and specificity (78.9% and 98.9%, respectively). Affinity chromatography using immobilized CZV1-1 resulted in a ≈ 600-fold enrichment of the antibodies from the serum that recognizes this synthetic molecule. Binding assays revealed that these enriched anti-CZV1-1 IgGs recognize the domain III (DIII) of the ZIKV envelope protein and show minimal reactivity to DIII of dengue virus envelope proteins. Binding competition studies of purified anti-CZV1-1 IgG against known ZIKV-specific monoclonal antibodies (mAbs) showed that CZV1-1 mimics a nonlinear neutralizing conformational epitope in DIII of the ZIKV envelope. Purified anti-CZV1-1 IgG neutralized infection of distinct strains of ZIKV in cell cultures with potencies comparable to highly specific ZIKV-neutralizing monoclonal antibodies. Molecular dynamics simulations revealed that anti-CZV1-1 IgG binds to ZV48, a highly specific ZIKV mAb that targets the C- C' loop epitope of ZIKV envelope DIII, with high affinity and displays a higher rate of native contacts, hydrogen bonds, and configurational stability within the binding site with ZV48 than other mAbs. Collectively, our findings reveal that systematic mining of 'antigenically agnostic' libraries of small molecules can be used to discover biomarker correlates of virus neutralization.

5738

PHARMACOKINETICS, TOLERABILITY AND SAFETY OF FAVIPIRAVIR COMPARED TO RIBAVIRIN FOR THE TREATMENT OF LASSA FEVER: A RANDOMIZED CONTROLLED OPEN LABEL PHASE II CLINICAL TRIAL

Mirjam Groger[1], Kevin Okwaraeke[2], Peter Akhideno[3], Meike Pahlmann[1], Christine Kleist[4], Cédric Mbavu[1], Julia Hinzmann[1], Veronika Schlicker[1], Femi Oluwasola Babatunde[3], Ndapewa Ithete[1], Osahogie Edeawe[3], Francisca Naana Sarpong[1], Camille Fritzell[5], Alexandre Duvignaud[5], Denis Malvy[5], Sylvanus Okogbenin[3], Marie Jaspard[5], Sebastian G. Wicha[4], Stephan Günther[1], Michael Ramharter[1], Oluwafemi Ayodeji[2], Cyril Erameh[3]

[1]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]Federal Medical Centre Owo, Owo, Nigeria, [3]Irrua Specialist Teaching Hospital, Irrua, Nigeria, [4]University of Hamburg, Hamburg, Germany, [5]Institut National de la Santé et de la Recherche Médicale 1219, Bordeaux, France

Lassa fever (LF) is a severe re-emerging infectious disease and defined as priority disease for urgent research and development by the World Health Organization. It is caused by the Lassa virus (LV) which belongs to the segmented negative strand RNA viruses of the family Arenaviridae. Transmission occurs primarily by spill-over from the animal reservoir but secondary cases with human to human transmission are common. LF affects a large number of countries in West Africa, with Nigeria carrying the highest case burden in the world. So far, treatment options are limited to supportive care and the antiviral ribavirin. Evidence for the efficacy of ribavirin in LF is, however, poor. A recent study conducted in Nigeria showed that in vivo plasma concentrations do not suffice to exert a relevant antiviral effect. New drugs for LF treatment are therefore urgently needed but no therapeutic trials have been conducted for this indication in the past decades. Favipiravir is a broad-spectrum antiviral registered for pandemic influenza that has previously been evaluated for Ebola virus disease and Covid-19. It has potent activity against LV in pre-clinical studies. The aim of this phase II clinical trial was to explore the pharmacokinetics, pharmacodynamics, safety and tolerability of favipiravir as repurposed drug in the treatment of LF. The trial was conducted at the Irrua Specialist Teaching Hospital and the Federal Medical Centre of Owo in Nigeria - the worldwide largest LF treatment centres. Blood samples for pharmacokinetic analyses were collected at 0.5, 1, 3, 5, 8, 12 and 24 hours after the first dose and at 0, 1 and 4 hours after drug administration on day 7. Besides clinical parameters, further sampling for virological, serological and immunological analyses as well as hematology and biochemistry safety was done on days 1, 2, and then every other day until the end of the study. Between 2021 and 2022, 40 LF patients were included in the trial. Trial results on cure rates, pharmacokinetics, safety and tolerability of this first GCP compliant phase II clinical trial will be presented to provide first insights into prospects of this new treatment candidate for LF.

5739

A BEAD-BASED MULTIPLEX SAMPLE-SPARING ANTIBODY ASSAY FOR DETECTING CURRENT AND PAST DENGUE AND ZIKA VIRUS INFECTIONS

Edwing C. Cuadra[1], Izabella N. Castillo[1], Demetrios L. Samaras[1], Lindsay C. Dahora[1], Filemon Bucardo[2], Megan E. Reller[3], Aravinda M. de Silva[1], Premkumar Lakshmanane[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]National Autonomous University of Nicaragua at León, Nicaragua, Leon, Nicaragua, [3]Duke Global Health Institute, Duke University,, Durham, NC, United States

Serological assays to identify recent or past flavivirus infections are needed for surveillance and predicting the risk of severe disease. The four dengue virus (DENV) serotypes and Zika virus (ZIKV) can co-circulate in the population. Prior immunity to one DENV serotype or ZIKV is a risk factor for severe disease during secondary DENV infection. Detecting viral RNA or non-structural protein during acute infection does not identify all acute infections due to brief viremia. Paired serology using the whole virus antigen is sensitive but lacks specificity to distinguish between DENV and ZIKV infections. To address this, we developed a multiplex immunoassay using beads coupled to DENV1-4 and ZIKV EDIII antigens to detect and distinguish acute and past infections. We tested 204 paired blood samples collected at acute and convalescent stages from febrile patients (2-77 years) during the 2016 Zika (n=30) and the 2018 DENV2 outbreaks (n=174) in León, Nicaragua. We developed an algorithm to detect and distinguish acute infections based on increased of EDIII antibody levels from acute to convalescence. Using EDIII binding pattern to the acute sample and our earlier validated algorithm for detecting past infection, we stratified acute infection by prior exposure. Compared to paired serology using whole viruses, the multiplex assay demonstrated a sensitivity of 90.1% and a specificity of 88.2% for detecting acute infections. Despite DENV and ZIKV background immunity being 85.7%, the multiplex assay correctly classified acute DENV or ZIKV infection for 91.9% and was indiscernible for 8.1% of individuals with >2 past DENV infections. The accuracy among the 14.3% naïve individuals for identifying DENV serotype or ZIKV infection was 100%. By comparison, RT-PCR missed one for every two symptomatic cases tested. Thus, the multiplex EDIII assay is robust, requires a small sample volume, and does not require handling virus to determine acute infection and past exposure to DENV and ZIKV. It offers a significant benefit for surveillance, estimating disease burden, and implementing control measures to reduce DENV and ZIKV transmission.

5740

DEVELOPMENT AND EVALUATION OF NOVEL NANOBODIES AGAINST ZIKA VIRUS INFECTION

Shuofeng Yuan, Jianli Cao, **Jasper Fuk-Woo Chan**

The University of Hong Kong, Hong Kong, Hong Kong

Zika virus (ZIKV) is a human-pathogenic flavivirus that has raised global concerns in recent years as it caused an unprecedented large-scale epidemic of congenital microcephaly and malformations. While the case number of ZIKV infection has seemingly decreased in the past few years, the actual incidence rate may be largely underestimated and ZIKV remains an important public health threat. Despite the clinical importance of ZIKV, treatment and prophylaxis options remain limited. Over 70 therapeutic anti-ZIKV monoclonal antibodies (mAbs) with moderate to high neutralizing activities have been reported, with some demonstrating antiviral effects in preclinical animal models. However, a major concern of these anti-ZIKV mAbs is the potential to induce antibody-dependent enhancement (ADE) of infection. The possibility of exacerbating disease progression by ADE has limited the clinical application of these anti-ZIKV mAbs. In this study, we constructed a nanobody (single-domain antibody) library by immunizing alpacas (Illama pacos) with recombinant ZIKV proteins and

identified a number of nanobodies with high affinity against ZIKV. Among them, a number of nanobodies targeting the ZIKV envelope (E) protein or nonstructural protein 1 (NS1) demonstrated potent anti-ZIKV activity in vitro in viral load reduction, plaque reduction, and cytopathic effect inhibition assays. Type I interferon receptor-deficient A129 mice treated with a single dose of any one of these nanobodies either as prophylaxis (before virus challenge) or treatment (after virus challenge) demonstrated significantly higher survival rate at 10-14 days post-infection (70-100% vs 0%, P<0.05) and lower viral burden in brain tissues. Importantly, ADE assay showed that these nanobodies did not induce ADE. Mechanistically, these nanobodies significantly downregulated interleukin-1-beta in vitro and in mice. Taken together, these results showed that nanobodies are effective antivirals against ZIKV infection without inducing ADE. Clinical trials should be considered to assess the prophylactic and therapeutic effects of anti-ZIKV nanobodies in endemic regions.

GENERATION OF THERAPEUTIC HUMAN MONOCLONAL ANTIBODIES AGAINST HANTAVIRUSES FROM HUMAN-IMMUNE-SYSTEM HUMANIZED DRAGA MICE

Ahmad Faisal Karim[1], Sounak Ghosh Roy[1], Teodor D. Brumeanu[2], Joseph Golden[3], Jay Hooper[3], Sofia A. Casares[1]

[1]Naval Medical Research Command (NMRC), Silver Spring, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]US Army Medical Research Institute for Infectious Diseases, Fort Detrick, MD, United States

Hantaviruses are rodent-transmitted viruses that cause Hantavirus Cardiopulmonary Syndrome (HCPS) and Hemorrhagic Fever with Renal Syndrome (HFRS) around the globe. Most hantavirus infections in Asia are caused by Hantaan (HTNV) and Seoul (SEOV), in America by Andes (ANDV) and Sin Nombre (SNV), and in Europe by Puumala (PUUV) and Dobrava-Belgrade (DOBV) virus strains. Collectively, 150,000-200,000 cases of hantavirus disease are reported annually, with a case fatality rate of 12% for HFRS and up to 40% for HCPS. Recent studies in Argentina and Chile reported that the hantavirus strain ANDV can potentially be spread between human through direct and close contact with an infected person. Moreover, the lack of effective vaccines and therapeutics makes hantavirus infections dangerous and raising concern for potential hantavirus pandemics. Humanized DRAGA mice infused with human hematopoietic stem cells from cord blood reconstitute a long-term functional human immune system and demonstrated as a rapid platform for generation of human monoclonal antibodies (hmAbs) against infectious diseases. Here, we primarily describe to identify, characterize and develop therapeutics antibodies against glycoprotein complex (Gn/Gc, M segment) of ANDV from DRAGA mice immunized with DNA-encoding vaccine. Using hybridoma technology, 1026 human B cell hybridoma clones were obtained from splenic human B cells fused with K6H6 myeloma cells. Among them, 63 (6%) hmAb clones showed significant binding affinities for ANDV Gn/Gc protein as determined by ELISA. Nine (14 %) of the ANDV specific hmAbs also showed bind to HTNV Gn/Gc protein; suggesting small pool of generated ANDV-specific hmAbs able to cross-react against two different strains (ANDV & HTNV). Ongoing studies are aimed at immune-characterization, by assessing cross-reactivity and neutralizing activity of these hmAbs with the goal of testing their protective and therapeutic efficacy against different strains of Hantaviruses in animal models. Highly cross-reactive hmAbs have potential as “universal” immunotherapeutics for the prevention of and treatment of hantavirus infections in humans.

5742

A NON-WHOLE GENOME SEQUENCING APPROACH FOR MONITORING SARS-COV-2 VARIANTS IN BURKINA FASO & KENYA

Caitlin Greenland-Bews[1], Sonal Shah[2], Alice J. Fraser[2], Samuel S. Serme[3], Kephas Otieno[4], Issiaka Soulama[3], Alphonse Ouedraogo[3], Issa Nebie[3], Tegwen Marlais[2], Alfred B. Tiono[3], Emily Adams[1], Simon Kariuki[4], Sodiomon B. Sirima[3], Chris Drakeley[2], Feiko O. ter Kuile[4], Thomas Edwards[1], **David J. Allen**[2]

The rapid emergence and global dissemination of SARS-CoV-2 highlighted a need for robust, adaptable surveillance systems. However, financial and infrastructure requirements for whole genome sequencing (WGS) mean most surveillance data has come from higher-resource geographies. Consequently, the molecular epidemiology of SARS-CoV-2 in low- and middle-income countries (LMICs) is limited, and there is a need for more cost-accessible technologies in LMICs to help close data gaps in variant surveillance. To address this, we developed a high-resolution melt curve (HRM) method targeting key variant-defining mutations in the SARS-CoV-2 genome, which give unique signature profiles that define different SARS-CoV-2 variants of concern (VOCs). Nasopharyngeal-oropharyngeal swabs from 178 participants (112 in Burkina Faso, 66 in Kenya) on the day of enrolment in the MALCOV (Malaria as a risk factor for COVID-19 in western Kenya and Burkina Faso) cohort study were used in the evaluation of the HRM assay and compared to WGS. A SARS-CoV-2 variant could be determined by both HRM and WGS for 74.7% of specimens. Overall, eleven distinct genotypes of SARS-CoV-2 were identified among Burkinabè and Kenyan cohorts, with Delta VOC most frequently detected. Additionally, the 19A strain, VOCs Alpha and Omicron, and other non-VOCs, including Eta, and those belonging to 19B, 20A, 20B, and 20E were detected, as was evidence of recombinant genomes. The sensitivity and specificity of the HRM assay compared to WGS were 100% and 94.6-100%, respectively, but varied by VOC. HRM-based assays can provide a lower-cost approach (<$1 per test) to conducting molecular epidemiology as part of wider surveillance strategies, particularly in settings where access to WGS is absent or limited. The HRM assay can be implemented on most modern real-time PCR instruments, which are already be available in most diagnostic facilities. Such assays can often be implemented with little capital investment. Additionally, the assay is readily adaptable and can focus on local epidemiological surveillance needs or be updated quickly to accommodate the emergence of a novel variant.

DETECTION OF BLOOD BIOMARKERS OF NEUROLOGICAL INJURY IN HUMAN CASES OF VIRAL ENCEPHALITIS AND SEVERE DISEASE

Maggie L. Bartlett[1], Heather Poeck-Goux[1], Linwood Johnson[1], Kevin L. Schully[1], Melissa Gregory[2], Joost Brandsma[2], Josh G. Chenoweth[2], Danielle V. Clark[2], Amy Y. Vittor[3], Ronald Hayes[4], Jean-Paul Carrera[5], **Darci R. Smith**[1]

[1]Naval Medical Research Command, Ft. Detrick, MD, United States, [2]The Henry Jackson Foundation, Bethesda, MD, United States, [3]University of Florida, Gainesville, FL, United States, [4]Banyan Biomarkers, San Diego, CA, United States, [5]Gorgas Memorial Institute, Panama City, Panama

Neurotropic viral infection and the ensuant immune response are a significant cause of morbidity and mortality worldwide, which can range in severity from mild to permanent central nervous system (CNS) damage and death. Encephalitic alphaviruses of military and public health concern include Venezuelan and eastern equine encephalitis viruses (VEEV and EEEV) and Madariaga virus (MADV; Alphavirus; Togaviridae), which are mosquito-borne viruses in the Americas that cause CNS disease in humans and equids. Injury to the CNS is an important determinant of poor outcome

and tools to predict this outcome are lacking. Glial fibrillary acidic protein (GFAP) and ubiquitin carboxy-terminal hydrolase L1 (UCH-L1) are proteins that when detected in the serum, signal astrocyte and neuronal injury, respectively. These biomarkers of CNS tissue injury could serve to better assess injury severity, monitor disease progression, direct treatment, and as reliable endpoints to help develop novel medical countermeasures. Recent advances in the use of blood-based biomarkers for diagnosis of traumatic brain injury (TBI) which have FDA approved assays have provided a scientific foundation for expanding the biomarker technology to brain damage caused by other CNS pathologies like viral encephalitis. Here we evaluated the ability to detect these biomarkers in the serum from multiple human cohorts with evidence of viral encephalitis or severe disease. Samples were collected from: 1) human cases infected with the alphaviruses VEEV subtype ID or MADV in Panama; 2) human cases of suspected sepsis in Cambodia and Ghana that were severely ill or diagnosed with encephalitis of unknown origin; 3) hospitalized patients with severe coronavirus disease (COVID-19). We found higher levels of GFAP and/or UCH-L1 in all cohorts and in some cases detection of these biomarkers could predict later developing cognitive impairment. Collectively, our results suggest that the detection of these blood-based biomarkers with an already FDA approved assay may be a good indicator for brain injury resulting from viral or other infections causing severe disease.

Given that SARS-CoV-2 is now known to infect a wide range of mammals, sustained animal surveillance is a critical tool to help protect public health and support early detection on emerging mutations and variants. We conducted a longitudinal One Health study in 47 households with active human COVID-19 cases in east central Texas during January-July 2022. We evaluated people (n=104; range 1-7 per house) and animals (n=101; 1-12 per house), by RT-qPCR, for the presence of SARS-CoV-2 at three sequential sampling points, each 1-2 weeks apart, with the first visit occurring 0-5 days from detection of the first person with COVID-19. Our study spanned the peak of the BA.1 Omicron wave to the BA.2/BA.5 wave. Household animals were predominantly dogs (n=57) and cats (n=29) but also included goats, horses, pigs, a donkey, a rabbit, a gecko and a tortoise (n=14). People tested positive (64%) by PCR in all but 4 houses. Positivity was highest (60%) in the first sampling than the second (48.5%) and third (20.4%). Serology from dried blood spots revealed antibodies against the spike glycoprotein in 95.7% of the people, indicating either vaccination or natural exposure. Only 5.3% (3/57) of dogs tested PCR-positive, including one with a PCR-positive food bowl, at days 2-9 after diagnosis of the first person in the household. All other animals were negative. Sequencing revealed the BA.2 Omicron in one dog. Positivity among dogs was similar to our prior, pre-Omicron study (n = 396; 6.3%; $\chi 2$, $P > 0.5$) but was higher among cats pre-Omicron (n = 158; 15.2%; $P < 0.05$) despite efforts toward early and multiple sampling in this study. Our longitudinal study found no evidence of onward transmission from the three infected dogs, as no infections were detected in coinhabiting animals at subsequent sampling points. Our results show that fewer animals became infected with Omicron despite its higher transmissibility among humans, suggesting that each variant may interact differently with animals in terms of susceptibility and transmissibility. These differences among variants emphasize the need for continued active surveillance in animal populations.

REAL-TIME DATA COLLECTION FOR EFFICIENT MICROPLANNING AND MONITORING OF NATIONAL DOG RABIES VACCINATION IN BANGLADESH

Sazid Ibna Zaman[1], MD Nurullah[1], S. M. Golam Kaisar[2], Kamrul Islam[2], Hasan Sayedul Mursalin[2], Md. Ismail Hossain[1], Kazi Nujhat Naila[3], Richard James Maude[1]

[1]Mahidol-Oxford Tropical Medicine Research Unit (MORU), Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Zoonotic Disease Control Program, CDC, DGHS, Dhaka, Bangladesh, [3]Department of Geography and Environment, Faculty of Earth and Environmental Sciences, University of Dhaka, Dhaka, Bangladesh

Rabies, the world's deadliest disease with 100% fatality, creates significant public health difficulties in the world's poorest regions. Bangladesh, has the third highest number of human deaths (2000-2500 annually) among all rabies endemic countries. The country's goal was to reduce the number of rabies cases by 90% by 2015 and to eliminate the disease entirely by 2030. The main approach to achieve this goal was to vaccinate dogs which initiated a mass dog vaccination program aiming to deliver 3 rounds vaccination across the country. To do this, microplanning was applied to reach every community to maximize vaccination coverage. For efficient monitoring and microplanning, KoboToolbox was used to collect real-time data of vaccinated dogs. Aggregated daily dog vaccination data were collected on paper forms since 2012 and from 2018 this was converted to electronic data collection using KoboCollect where at the first part, dog vaccination was reported daily in aggregation and later at individual level in the same year with geolocation and photos. From 2018 to 2022, information on 1.6 million dogs was collected with 58.6% data containing the geo-locational data of dogs and 41.3% had no geo-locational data. Average vaccinated dog coverage was 81.6% covering the whole country. Correlation between reported rabies cases and vaccination coverage from 2012 to 2022 including aggregated and individual level gave a coefficient of -0.769 which demonstrates the effectiveness of the program. The shift from aggregate to individual level helped in improving vaccine delivery in progressive rounds as the increasingly granular data was used to identify locations with lower coverage, thus improving possible planning for future rounds to ensure maximum vaccination coverage. Although the system is easy to run and maintain but still there are data with no geo-location. To address this additional training and improved technical support are needed to maximize data completeness for optimal geo-enabled microplanning.

5746

GENETIC ADAPTATION OF NONTYPHOIDAL SALMONELLA IN HUMANS, ANIMALS AND IN THE ENVIRONMENT-ANTHROPONOTIC TRANSMISSION?

Denise Dekker[1], Thorsten Thye[1], John Luingu[2], Daniel Minja[2], Sandra Simon[3], Ralf Krumkamp[1], Linda Ofori[4], Samwel Gesase[2], Richard Phillips[5], Charity Wiafe-Akenten[6], Ellis Paintsil[5], Joyce Mbwana[2], Antje Flieger[3], Jürgen May[1]

[1]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]National Institute for Medical Research, Tanga, Tanzania, United Republic of, [3]Robert Koch Institute, Wernigerode, Germany, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]Kumasi Center for Collaborative Research, Kumasi, Ghana, [6]Kumasi Center for Collaborative Research, Kumasi, Germany

Nontyphoidal Salmonella (NTS) causes more than 1.2 million annual deaths worldwide, the majority in resource-limited countries such as sub-Saharan Africa (SSA). NTS have also become increasingly resistant to antibiotics and are the most frequent cause of bacteraemia in SSA. Recent data suggests that this typically livestock- associated pathogen has genetically developed and adapted to different hosts and environments, proposing anthroponotic transmission. Within this study, we collected Salmonella from humans (stool and blood), animals and the environment (dust and soil), in Tanzania and in Ghana. Strains were identified by biochemical methods and confirmed using the VITEK 2 System. Serotyping and antibiotic susceptibility testing was performed. Further, isolates were subjected to sequencing using a

NextSeq 500 Illumina machine.9,099 samples were collected. From these, 222 NTS were identified comprising 58 serovars. The highest level of resistance was in humans with fluroquinolone resistance on the increase and multidrug resistance (MDR) highest in isolates from blood cultures (24%, n/N=11/46). Of the invasive strains, MLST analysis confirmed the serovars and sequence types S. Typhimurium (ST313/ST19) being most common followed by S. Enteritidis (ST11/ST1479) and S. Dublin (ST10). A sequence type overlap amongst humans and livestock or environmental strains was detected for ST19.Our study demonstrates a broad serovar distribution of Salmonella from livestock and the environment not typically associated with human infections. The substantially high level of MDR and emerging fluoroquinolone resistance seen in the invasive NTS poses a challenge to current treatment strategies. Interestingly, we found ST19 more common in invasive human disease but also prevalent in samples from livestock compared to ST313, only seen in human samples. These findings are not in line with previous results, mainly from East Africa where ST313 was identified as the dominant sequence type in disseminated human disease, strongly indicating anthroponotic transmission of ST313 but not of ST19 in SSA.

5747

MOLECULAR AND SEROLOGICAL EVIDENCE OF CRIMEAN-CONGO HEMORRHAGIC FEVER VIRUS IN LIVESTOCK AND TICKS IN CAMEROON

Francine Berlange Sado Yousseu[1], Huguette Simo[2], François-Loïc Cosset[3], Natalia Bezerra de Freitas[3], Basile KAMGANG[1], Philip J. McCall[4], Roland NDIP NDIP[5], Vincent Legros[3], Charles S. Wondji[1]

[1]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [2]Centre Pasteur of Cameroon, Yaounde, Cameroon, [3]Centre international de recherche en infectiologie, Lyon, France, [4]Liverpool School of Tropical Medicine and Hygiene, Liverpool, United Kingdom, [5]University of Buea, Buea, Cameroon

Crimean-Congo haemorrhagic fever (CCHF) is a widespread tick-borne zoonotic disease, responsible of haemorrhagic symptoms in humans, with a reported case fatality rate of up to 40%. This disease is caused by Crimean-Congo haemorrhagic fever orthonairovirus (CCHFV). Little is known about the occurrence of CCHFV in ticks and animals in Cameroon. Hence this study aimed to determine the prevalence of CCHFV in domestic ruminants and identify its potential tick vector in Cameroon. A cross-sectional study was carried out in two livestock markets of Yaoundé in 2019, 2020, and 2021. Blood and ticks were collected from cattle, sheep, and goats. Anti-CCHFV specific antibodies were detected in plasma using a commercial double antigen Enzyme-Linked Immunosorbent Assay (DA-ELISA) assay. DA-ELISA- positive and a subset of negative samples were further tested by a seroneutralization assay for confirmation. Ticks were screened for the presence of orthonairoviruses by amplification of a fragment of the L segment and the genetic evolution of the virus was inferred by maximum likelihood. Overall, 756 plasma samples were collected from 441 cattle, 168 goats, and 147 sheep. The seroprevalence of anti-CCHFV antibody was 61.77% for all animals, with the highest rate in cattle (433/441, 98.18%) followed by sheep (23/147, 15.65%), and goats (11/168, 6.55%), (p-value < 0.0001). The highest seroprevalence rate was found in cattle from the Sahelian region of Cameroon (100%). Overall, 1500 ticks of the Rhipicephalus (773/1500, 51.53%), Amblyomma (341/1500, 22.73%), and Hyalomma (386/1500, 25.73%) genera were screened. CCHFV was identified in one Hyalomma truncatum pool collected from cattle. Phylogenetic analysis of the L segment classified this CCHFV strain within the African genotype III. These findings undoubtedly demonstrate for the very first time the circulation of CCHFV in Cameroon with the identification of genotype III. The results also highlight the necessity for more studies on CCHFV using a One Health approach and targeting at-risk human and animal populations, as well as ticks in high-risk areas of the country.

5748

MOLECULAR CHARACTERIZATION OF EXTENDED - SPECTRUM BETA - LACTAMASE PRODUCING KLEBSIELLA PNEUMONIAE AMONG CHILDREN AND LIVESTOCK IN RURAL KOROGWE, TANZANIA

Neyaz Ahmed Khan[1], Joyce Mbwana[2], Thorsten Thye[3], John Lusingu[2], Hagen Frickmann[4], Charity W. Akenten[5], Joseph Kaseka[2], Maike Lamshöft[3], Samwel Gesase[2], Daniel Minja[2], Jürgen May[3], Ralf Krumkamp[3], Wolfgang Streit[6], Denise Dekker[1]

[1]One Health Bacteriology group, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]National Institute for Medical Research, Tanga, Tanzania, United Republic of, [3]Department Infectious Disease Epidemiology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [4]Department of Microbiology, Virology and Hygiene, University Medicine Rostock, Rostock, Germany, [5]Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, [6]Department of Biology, University of Hamburg, Hamburg, Germany

Extended-spectrum beta lactamase- (ESBL) producing Klebsiella spp. are a global concern, and are on the increase, worldwide. This is mainly attributed to the overuse of antibiotics not only in human medicine but also in animal farming, also in Tanzania. Studies have been conducted on the prevalence of ESBL in children in Tanzania, but few studies have examined Klebsiella in livestock as a possible transmission reservoir. Using a one-health approach, this study investigated the frequency of ESBL-KP and antibiotic resistance in humans and livestock in rural Tanzania. This cross-sectional study was conducted from February 2019 to July 2020 and enrolled study participants at the outpatient department of Magunga Hospital (Korogwe). Stool samples were collected from children aged five and younger with and without diarrhea. Faecal specimens from livestock were sampled at commercial farms or smallscale farms in communities within the Korogwe District. Strains were identified using a chromogenic agar and confirmed using the VITEK2 Compact System. Antimicrobial susceptibility testing was performed by disc diffusion, and isolates subjected to whole genome sequencing using the NextSeQ500 Illumina machine. Of 258 asymptomatic and 259 children with diarrhoea, 16 (6%) and 32 (12%) tested positive for ESBL-KP, respectively. Furthermore, ESBL-KP was detected in 54 (7%) samples from chicken, one (3%) sample from pigs, and one (4%) sample from goats. All isolates were resistant to beta-lactams and cepholosporins and susceptible to carbapenems and tetracyclines. Whole genome analysis revealed ST17 to be the most common sequence type, and phylogenetic analysis revealed thirteen very closely related human and livestock isolate clusters. The results demonstrate the presence of ESBL-KP in human and chicken populations with ESBL-KP being closely related in the two reservoirs under investigation. Livestock represent a potential reservoir for transmission of ESBL-KP to humans. It is therefore essential to implement measures using a one health approach in order to control the spread and transmission of this pathogen.

5749

RECONSTRUCTING RODENT CONTACT NETWORKS FROM TRAPPING DATA TO UNDERSTAND LASSA FEVER TRANSMISSION NETWORKS

David Simons[1], Rory Gibb[2], Umaru Bangura[3], Ravi Goyal[4], Rashid Ansumana[5], Deborah Watson-Jones[6], Richard Kock[1], Kate E. Jones[2]

[1]The Royal Veterinary College, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [4]University of California San Diego, San Diego, CA, United States, [5]Njala University, Bo, Sierra Leone, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

Lassa fever (caused by Lassa mammarenavirus) is a zoonotic infectious disease endemic to West Africa. Outbreaks of rodent-to-human infections are regularly reported from Nigeria, Sierra Leone and Liberia with sporadic outbreaks reported from elsewhere in the region. The primary rodent reservoir of this pathogen is Mastomys natalensis although evidence of infection has been identified in eleven other rodent species across

the region. The role of these other rodent species in the maintenance and transmission of viral populations among rodent communities is not understood. It is likely the spatially heterogeneous outbreaks of Lassa fever observed in human populations are indicative of complex viral and host population dynamics among rodent communities. Here we use rodent trapping data and rodent serology from a two year study in a Lassa fever endemic region of Sierra Leone, comprising more than 40,000 trap nights and 650 rodent detections to describe rodent communities across landuse gradients and to reconstruct rodent contact networks that will determine viral transmission. We find that rodent communities are structured along gradients of anthropogenic landuse disturbance moderating the hazard of exposure to reservoir species'. We further find that the primary reservoir of Lassa fever displays differential inter- and intra-specific contact rates across these landuse types which will affect the potential of viral persistance in these communities. These findings are important for understanding the dynamic risk of pathogen spillover in human communities. Findings from this study can guide future One Health focussed interventions and are of particular interest when conducting research attempting to assess the prevalence of Lassa fever and risk of spillover.

5750

HEALTHY CHILDREN, HEALTHY CHIMPS: A RESEARCH-PRACTICE PARTNERSHIP FOR REDUCING RESPIRATORY DISEASE TRANSMISSION FROM HUMANS TO CHIMPANZEES IN UGANDA

Taylor Weary[1], Tressa Pappas[2], Patrick Tusiime[3], Shamilah Tuhaise[3], Elizabeth Ross[3], James Gern[2], Tony Goldberg[1]

[1]University of Wisconsin School of Veterinary Medicine, Madison, WI, United States, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI, United States, [3]The Kasiisi Project, Fort Portal, Uganda

Respiratory disease is a major cause of morbidity and mortality among people in the developing world and also threatens great apes across Sub-Saharan Africa. Our studies of wild chimpanzees in Kibale National Park, Uganda, have identified the causative agents of respiratory disease outbreaks as "common cold" pediatric human pathogens, but reverse zoonotic transmission pathways have remained unclear. Between May 2019 and July 2022, we collected approximately 2,000 paired respiratory symptoms surveys and nasopharyngeal swabs from 264 people (local children and forest workers) and over 700 fecal samples from 141 chimpanzees as part of a prospective cohort study. We characterized respiratory pathogens using a multiplex PCR panel and metagenomic DNA sequencing and examined the transmission risk of various pathogen types, seasons, social factors, and the individual characteristics of humans and chimpanzees. Children exhibited high incidence rates and symptom severities, whereas adults were largely asymptomatic. COVID-19 lockdown in 2020-2021 significantly decreased respiratory disease incidence. Human symptoms peaked in February. In chimpanzees, the most common month for respiratory disease outbreaks was March. Rhinovirus, which caused a 2013 outbreak that killed 10% of chimpanzees in a Kibale community, was the most prevalent human pathogen throughout the study. Rhinovirus was also most prevalent during February and was the pathogen most likely to be carried asymptomatically by people. Our data suggest that respiratory pathogens circulate in children living near Kibale, and that adults in the same communities become asymptomatically infected and may carry the pathogens into the forest and infect chimpanzees. The "Healthy Children, Healthy Chimps" program reflects our hope that reverse zoonotic disease transmission to chimpanzees can be mitigated through a One Health approach that considers the health of chimpanzees and local people to be linked.

5751

ASSESSING SHIFTS IN BITING PATTERNS OF ANOPHELES GAMBIAE AND AN. FUNESTUS, THE MAJOR MALARIA VECTORS IN SOUTHEASTERN TANZANIA

Janice S. Maige[1], Alphonce A. Assenga[2], Tegemeo Gavana[2], Gloria S.G Shirima[3], Protas Sayo[2], Yeromin Mlacha[2], Samson S. Kiware[4], Prosper Chaki[2]

[1]University of Dar es Salaam, Dar es Salaam, Tanzania, United Republic of, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [3]The Nelson Mandela African Institution of Science and Technology, Arusha, Tanzania, United Republic of, [4]Pan-African Mosquito Control Association, Nairobi, Kenya

Long-lasting Insecticidal Nets (LLINs) and Indoor Residual Spraying (IRS) are key vector control strategies in malaria control initiatives in Africa, including Tanzania. However, the prolonged use of LLINs and IRS has led to mosquitoes developing physiological and behavioral resilience to insecticides, resulting in increased residual malaria transmission that threatens malaria elimination efforts. To assess how mosquito-biting behavior changes could impact malaria epidemiology in Tanzania's southeastern area, a study was conducted using the mosquito electric trap (MET), collecting Anopheles mosquitoes weekly (18:00 - 06:00) from 22 villages from November 2019 to September 2020 in the Rufiji, Kilwa, and Kibiti districts. For each house, two METs were employed; one trap was set inside the house and the other was positioned 15 meters away outside the house. Each trap included a volunteer. A total of 3,586 An. mosquitoes were collected, 1,912 (53.32%) An. gambiae, 1,666 (46.46%) An. funestus, 7 (0.2%) An. coustan, and 1 (0.03%) An. pharoensis. An. gambiae exhibited a greater preference for outdoor biting, at a rate of 0.32 bites per person per hour during 20:00-21:00hr, increasing progressively through the night to reach a peak of 0.48 bites per person per hour during 00:00-01:00hr, while An. funestus showed a higher preference for indoor biting at a rate of 0.35 bites per person per hour indoors and 0.29 bites per person per hour outdoors. This study revealed, for the first time, that An. gambiae density is higher outdoors than indoors in southeastern Tanzania's Kibiti, Rufiji, and Kilwa districts, indicating a behavioral shift of this crucial malaria vector from primarily indoor biting to outdoor biting. These findings highlight the necessity of promptly implementing supplementary interventions to control outdoor biting malaria vectors with the goal of managing residual malaria transmission and ultimately achieving complete elimination.

5752

THE ROLE OF SEROTONIN IN MOSQUITO SWARMING AND AUDITORY PERCEPTION OF MATES

David A. Ellis, Judit Bagi, Scott Tytheridge, Marta Andres

University College London, London, United Kingdom

Mating is an important aspect of vector biology and is crucial for current control strategies, such as SIT and Gene Drive. It also represents a target for novel control tools. Anopheles mosquitoes mate in swarms at dusk. Within these noisy swarms, males locate females by listening for their wingbeat frequency. However, the molecular underpinning of this process is poorly understood, and greater insight could benefit vector biology and even identify new targets for vector control. We are investigating the contribution biogenic amines to the regulation of this behaviour. One such amine, serotonin, has many well documented roles, for example in human depression. However, serotonergic neurotransmission isn't unique to humans and is found throughout the animal kingdom, particularly in efferent signalling systems, where signals are carried away from the central nervous system to tune peripheral effectors. Mosquitoes have highly complex hearing and are the only documented insect with an auditory efferent system. Our research suggests that this efferent input modulates both swarming itself, and hearing within the swarm. We have found that levels of serotonin show distinct periodic cycles, peaking around dusk. By chemically altering serotonin levels, we see changes in dusk-associated activity - a central feature of mosquito swarming. Furthermore, 3/6 serotonin receptors identified in A. gambiae are highly expressed in the male ear. All three are

G-protein-coupled receptors - highly “druggable” pharmacological targets. Using CRISPR, we have disrupted these vector control targets, and begun characterising their role in audition, swarming, and ultimately reproduction. Initial results show at least two have male-mating phenotypes. We are currently investigating the basis of these phenotypes by interrogating mutant phonotactic behaviour (male attraction to female tones) as well as their biophysical and electrophysiological responses. Thus, in addition to its broad role in swarming, we are beginning to understand the molecular underpinnings of serotonergic signalling within the context of hearing and partner-detection inside the swarm.

5753

A SEMI-FIELD SYSTEM TO DEFINE THE CHEMOSENSORY BASIS OF MALARIA TRANSMISSION AT HIGH DEFINITION

Diego Giraldo[1], Stephanie Rankin-Turner[1], Abel Corver[2], Genevieve M. Tauxe[1], Anne L. Gao[1], Dorian M. Jackson[1], Limonty Simubali[3], Christopher Book[3], Jennifer C. Stevenson[3], Philip E. Thuma[3], Rajiv C. McCoy[2], Andrew Gordus[2], Monicah M. Mburu[3], Edgar Simulundu[3], Conor J. McMeniman[1]

[1]W. Harry Feinstone Department of Molecular Microbiology and Immunology, Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]Department of Biology, Johns Hopkins University, Baltimore, MD, United States, [3]Macha Research Trust, Choma District, Zambia

Heterogeneity in mosquito biting risk is a key factor influencing malaria epidemiology. To gain insight into the chemosensory basis of mosquito attraction towards the scent of some humans versus others in a malaria endemic setting, we developed a large-scale, multi-choice system that quantifies mosquito olfactory preferences under naturalistic semi-field conditions in Zambia. Using infrared video tracking in an expansive flight cage arena, we engineered a high-content mosquito behavioral assay that tracks landing preferences of the African malaria mosquito Anopheles gambiae towards heated targets mimicking human skin temperature that are baited with whole body odor from sleeping humans or other host-related olfactory stimuli. Using this multi-choice system, we determined that An. gambiae prefers to land on heated targets baited with CO2 emissions reflective of a large human over environmental air, body odor from one human over CO2, and the scent of one human over another. When simultaneously presented with a choice between the scent of six humans, we identified individuals at both ends of the attractiveness spectrum who are consistently more or less attractive relative to other humans over replicate nightly trials. Applying integrative whole body volatilomics across these humans, we have identified a panel of airborne compounds including specific volatile carboxylic acids putatively associated with modulating human attractiveness to this prolific malaria vector. The comparative power of this multichoice preference assay may now readily be used to define the chemosensory basis of malaria transmission at high definition.

5754

IS THE INVASION AND SPREAD OF THE URBAN MALARIA VECTOR ANOPHELES STEPHENSI INTO AND ACROSS AFRICA MEDIATED BY WINDBORNE MIGRATION?

Tovi Lehmann[1], Roland Bamou[1], Jason Chapman[2], Don Reynolds[3], Peter Armbruster[4], Adama Dao[5], Alpha Yaro[6], Tom Burkot[7], Yvonne-Marie Linton[8]

[1]NIH, Bethesda, MD, United States, [2]Exeter University, Exeter, United Kingdom, [3]University of Greenwich, Greenwich, United Kingdom, [4]Georgetown University, Washington, DC, United States, [5]Mali ICEMR, Bamako, Mali, [6]ICER Mali, Bamako, Mali, [7]James Cook University, Cairns, Australia, [8]WRAIR, Silver Spring, MD, United States

The invasion of the urban malaria vector Anopheles stephensi into Africa is a serious public-health threat and a challenge to malaria elimination. Whereas malaria in Africa has been primarily a rural problem, the recent establishment and expansion of the invasive urban Asian vector Anopheles stephensi will likely drastically increase the risk in Africa, elevating urban malaria. It is widely believed that this incursion and subsequent spread was mediated by transport on ships, airplanes, and cars. Here, we examine the geographic, genetic, and related data and propose that the invasion and spread of An. stephensi in Africa has been mediated primarily by high-altitude windborne migration. The key evidence supporting windborne invasion and spread include i) the gradual range expansion over serval decades exhibits an unmistakable diffusion process, ii) distribution that does not concentrate near major sea ports, airports, or even main highways, but is correlated with predominant winds, iii) genetic evidence of high diversity that is incompatible with a single introduction such as by a ship and similarity between populations from southern Arabia (Yemen) with those in Africa, and iv) low tolerance of An. stephensi eggs to desiccation limiting their capacity for long travel, but strong capacity of gravid Anopheles females to to be carried by wind for tens or hundreds of kilometers. To our knowledge, no An. stephensi mosquitoes were intercepted on ships or other vehicles, nor in high altitude (>100 m above ground); however, sampling should be carried out to evaluate both possible modes of transport. The possibility of windborne migrations of gravid An. stephensi should be incorporated in surveillance efforts while testing this and the transport of these mosquitoes in human vehicles in tandem. Understanding the contributions of the different mechanisms of spread is critical to mitigating the impact of An. stephensi and other invasive vectors in future.

VECTOR AND HOST DIVERSITY SHAPE WEST NILE VIRUS TRANSMISSION IN URBAN GREEN SPACES ALONG AN URBAN-RURAL TRANSECT

Andrew Mackay[1], Jiayue Yan[1], Chang-Hyun Kim[1], Seth Magle[2], Maureen Murray[2], Mike Ward[1], **Chris M. Stone**[1]

[1]University of Illinois Urbana-Champaign, Champaign, IL, United States, [2]Urban Wildlife Institute, Lincoln Park Zoo, Chicago, IL, United States

Urban green space is associated with a wide range of societal benefits, including for conservation, human well-being, and to mitigate effects of climate change. Relatively little however is known regarding the importance of urban green spaces for West Nile virus transmission dynamics and whether this role changes as one moves further away from the urban core. To elucidate this, we set out traps at 10 sites in the Greater Chicago area that spanned a transect from the heart of the city to the rural edge. Specimens were collected weekly between June and October, identified to species, and pools of Culex pipiens, Cx. restuans, and Cx. salinarius tested for the presence of WNV. The host species from which blood meals were obtained in blood-fed females was determined through MiSeq sequencing. We monitored the relative activity of medium- and large mammals with camera traps and estimated avian abundance by performing point counts at three times during the summer at each site. Blood-meal origins for Cx. pipiens and Cx. restuans females were predominantly from avian species such as American robins and Northern cardinals and did not differ strongly between more urban and more rural sites. For Cx. salinarius, a possible bridge vector, white-tailed deer and humans were the most common hosts, but the relative frequency of blood meals taken on humans increased in the more urban locations. West Nile infection rates differed significantly among vector species and sites. To explain variation in prevalence we assessed the impact of land use and environmental parameters. The amount of impervious surface around the collection site itself was only weakly associated with WNV infection rates, but the proportion of land consisting of turf grass had a significant positive relationship. WNV prevalence was also significantly associated with the community competence index, as well as with abundance of species including American robins and house sparrows. Together, this work highlights that urban green space with certain characteristics that provide ample suitable habitat for important avian host species with repercussions for risk of WNV exposure in humans.

MOSQUITO GENE SURVEILLANCE (MGSURVE): A FRAMEWORK TO OPTIMIZE TRAP PLACEMENT FOR GENETIC SURVEILLANCE OF MOSQUITO POPULATIONS

Hector Manuel Sanchez Castellanos[1], David L. Smith[2], John M. Marshall[1]

[1]University of California Berkeley, Berkeley, CA, United States, [2]Institute for Health Metrics and Evaluation, Seattle, WA, United States

Genetic surveillance of mosquito populations is becoming increasingly relevant as genetics-based mosquito control strategies advance from laboratory to field testing. Especially applicable are mosquito gene drive projects, the potential scale of which leads monitoring to be a significant cost driver. For these projects, monitoring will be required to detect unintended spread of gene drive mosquitoes beyond field sites, and the emergence of alternative alleles, such as drive-resistant alleles or non-functional effector genes, within intervention sites. This entails the need to distribute mosquito traps efficiently such that an allele of interest is detected as quickly as possible - ideally when remediation is still possible. Additionally, insecticide-based tools such as bednets are compromised by insecticide-resistance alleles for which there is also a need to detect as quickly as possible. To this end, we present MGSurvE (Mosquito Gene SurveillancE): a computational framework that optimizes trap placement for genetic surveillance of mosquito populations such that the time to detection of an allele of interest is minimized. A key strength of MGSurvE is that it allows important biological features of mosquitoes and the landscapes they inhabit to be accounted for, namely: i) resources required by mosquitoes (e.g., food sources and aquatic breeding sites) can be explicitly distributed through a landscape, ii) movement of mosquitoes may depend on their sex, the current state of their gonotrophic cycle (if female) and resource attractiveness, and iii) traps may differ in their attractiveness profile. Example MGSurvE analyses are presented to demonstrate optimal trap placement for: i) an Aedes aegypti population in a suburban landscape in Queensland, Australia, and ii) an Anopheles gambiae population on the island of São Tomé, São Tomé and Príncipe. Further documentation and use examples are provided in the vignettes at the project's repository. MGSurvE is freely available as an open-source Python package on pypi. It is intended as a resource for both field and computational researchers interested in mosquito gene surveillance.

DESIGN AND PRELIMINARY FIELD VALIDATION OF A HANDHELD TOOL FOR AUTOMATED MORPHOLOGICAL IDENTIFICATION OF MOSQUITO SPECIES, SEX, AND ABDOMINAL STATUS BY VILLAGE HEALTH TEAMS IN UGANDA, FOR COMMUNITY-BASED VECTOR SURVEILLANCE

Soumyadipta Acharya[1], Deming Li[1], Shruti Hegde[1], Aravind S. Kumar[1], Saisamhita Dasari[1], Bhavya Gopinath[1], Carter J. Gaulke[1], Sunny Patel[1], Rebecca Rosenberg[1], Janis Iourovitski[1], Summer Duffy[1], Christina Hummel[1], Onanyang David[2], Kaweesa James[2], Kigongo Siriman[2], Batte D. Jovan[2], Venkat Mukthineni[1], Khalil Merali[1], Radha V. Taralekar[1]

[1]Johns Hopkins University, Center for Bioengineering innovation and Design, Baltimore, MD, United States, [2]Vector Borne and Neglected Tropical Diseases Control Division, Ministry of Health, Kampala, Uganda

Vector surveillance, a critical pillar of malaria control and elimination strategy, is limited by the global lack of trained medical entomologists and Vector Control Officers (VCOs), especially in low- and middle-income countries. We present the design of VectorCam, a novel Artificial Intelligence-enabled handheld field tool that automatically identifies the species, sex, and abdomen status of wild-caught mosquitos. The system consists of a low-cost smartphone running an Android application attached to low-cost hardware that can uniformly magnify and illuminate at a set distance. The system can effectively task-shift vector surveillance to Village Health Teams (VHTs), allowing them to rapidly image a batch of specimens and pack them into individual Eppendorf tubes with unique identifiers for quality assurance. This tool was designed with the iterative feedback of over 60 VHTs and 10 VCOs in Uganda through multiple formative usability studies that finalized the design and performance parameters. The core algorithm uses a Convolutional Neural Network architecture run on smartphones without internet connectivity. The classification accuracy against molecular identification using wild-caught mosquito specimens was as follows: Anopheles funestus s.l. (96%), An. gambiae s.l. (94%), other Anophelines (91%), Culex sp. (97%), and other genera (97%), with an overall F-1 macro score of 95 ±3%. A recent addition to the algorithm included An. stephensi, an invasive species of concern in Africa. With colony-bred specimens of An. stephensi, we achieved a classification accuracy of 98%. Accuracy for sex and abdominal status against morphological labeling by VCOs presented as 95±1%, and 86±4%, respectively. VHTs were placed in pairs of imaging and loading roles to evaluate their effectiveness in using VectorCam. They were trained by VCOs for an average of four hours, resulting in an average imaging speed of 1:11 ± 0:38 minutes per mosquito. VectorCam is a novel system that could help task-shift a major expertise bottleneck in Africa and Asia, allowing for a community-based approach towards vector surveillance.

ELUCIDATING THE INTERACTIONS OF PFCRT AND PLASMEPSINS 2/3 IN MODULATING FITNESS AND RESISTANCE IN PLASMODIUM FALCIPARUM TO PIPERAQUINE AND OTHER ARTEMISININ PARTNER DRUGS

Davin Hong[1], Satish K. Dhingra[2], Tomas Yeo[2], David A. Fidock[2], Sachel Mok[2]

[1]Nanyang Technological University, Singapore, Singapore, [2]Columbia University Irving Medical Center, New York, NY, United States

Failure of dihydroartemisinin and piperaquine (DHA+PPQ) combination therapy (ACT) in Southeast Asia has been linked to the Plasmodium falciparum KEL1/PLA1 co-lineage, which harbors the DHA resistant Kelch13 (k13) C580Y mutation and PPQ-resistant marker multicopy plasmepsins 2 and 3 (pm2/3). PPQ resistance-associated novel mutations in the P. falciparum chloroquine resistance transporter (pfcrt) including F145I or M343L, have also emerged on KEL1/PLA1 parasites expressing the Southeast Asian Dd2 pfcrt allele. However, it is unclear whether multicopy pm2/3 or mutant pfcrt is the major determinant of PPQ resistance in clinical isolates, and how they impact the efficacy of other ACT partner drugs. To examine the contributions of these PPQ-resistant markers, we generated an isogenic panel of CRISPR/Cas9 pfcrt-edited parasites harboring 1 to 3 copies of pm2/3 from progeny derived from the genetic cross of NF54 and RF7, a KEL1/PLA1 parasite. PPQ dose assays revealed that pfcrt is epistatic to pm2/3 in conferring high-level PPQ resistance, and both pfcrt M343L and pm2/3 amplification were necessary to produce a biphasic response at >1 μM PPQ. In addition, we identified Dd2 pfcrt and multicopy pm2/3 as key determinants of resistance to MMV675939, a preclinical compound. In contrast, the African 3D7 pfcrt allele led to a ~3-fold increased sensitivity to ACT drugs, lumefantrine and mefloquine, when compared to the Southeast Asian Dd2+M343L isoform. We also performed long-term competitive fitness assays between isogenic RF7 clones harboring 1 or 3 copies of pm2/3 to investigate fitness costs. Our results revealed that multicopy pm2/3 led to a moderate parasite fitness defect in the absence of drug pressure. Overall, our findings suggest that PPQ selects for pm2/3 amplification in mutant pfcrt parasites, and the poor fitness associated with multicopy pm2/3 may explain the loss of pm2/3 amplification in clinical isolates upon the switch from DHA+PPQ to artesunate+mefloquine. Furthermore, we demonstrate higher sensitivity of PPQ-resistant pfcrt alleles to lumefantrine and mefloquine, thus reinforcing their appeal as effective ACT drugs in Southeast Asia.

UNDERSTANDING LEAD DISCOVERY ANTIMALARIAL DRUGS RESISTANCE TRANSLATION FROM LAB TO FIELD PARASITES TOWARD SUSTAINABLE MALARIA ELIMINATION

Fatoumata O. Maiga, Laurent Dembélé, Mohamed Maiga, Ousmaila Diakité, Fanta Sogoré, Sekou Sissoko, Antoine Dara, Abdoulaye A Djimde

Université des Sciences, des Techniques et des Technologies de Bamako (USTTB), Faculté de Pharmacie, Malaria Research and Training Center (MRTC), Point G. PBE : 1805., Bamako, Mali

Not anticipated chloroquine resistance has had serious consequences for public health worldwide. It has subsequently led to the use of artemisinin-based combination therapies (ACTs) as first-line treatments for Plasmodium falciparum malaria. The aim of drug combinations was to anticipate appearance and spread of artemisinin resistant parasite on the field by protecting short-life artemisinin with long lasting existing antimalarial drug. Thus,for chloroquine, atovaquone, pyrimethamine and the current frontline artemisinin, major investigations have not been made at early discovery stage to identify which gene, mutations or conditions will cause drug resistance and can translate into field parasites. It has taken years to figure out the molecular determinant driving the resistance until complete loss of the drug.The discovery process of new alternative molecules to anticipate loss of ACTs should subsequently investigative their drug resistance markers that can translate from lab to field parasites and select partner drug accordingly for combination to ensure long lasting use of new antimalarial drug after their approval and field deployment. In a proof of concept study, we demonstrated that some key mutations found in lab parasites translate into field parasite conferring field parasites drug resistance Merck M5717 antimalarial drug candidate. With the great vision to ensure efficient long-term use M5717, we applied mathematical modelling to isobologram data to show that Pyronaridine is a viable partner for M5717. We extended this study to one of the most advanced lead discovery antimalarial, Novartis KAF156 which is currently in phase IIb clinical trial entering to phase III. We report that when exposed to GNF179 (Imidazolopiperazine: IPZ), close analogue of KAF156, recrudescent field parasites were detected which is being investigated for resistance purpose. This approach allows us to study the presence of resistant genes in field strains and predict resistance to antimalarial drugs, in order to anticipate therapeutic combinations before the new molecules are deployed.

CONFIRMED ARTEMISININ PARTIAL RESISTANCE AND HIGH EFFICACY OF ARTEMETHER - LUMEFANTRINE AND ARTESUNATE - AMODIAQUINE FOR THE TREATMENT OF UNCOMPLICATED PLASMODIUM FALCIPARUM MALARIA IN NORTH-WESTERN TANZANIA

Deus S. Ishengoma[1], Celine I. Mandara[1], Rashid Madebe[1], Catherine Bakari[1], Misago D. Seth[1], Filbert Francis[2], Creyton Buguzi[1], Issa Garimo[3], Samwel Lazaro[4], Abdallah Lusasi[4], Sijenunu Aron[4], Frank Chacky[4], Ally Mohamed[4], Ritha J.A Njau[5], Jovin Kitau[6], Jeffrey Bailey[7], Jonathan Juliano[8], Marian Warsame[9], Pascal Ringwald[10]

[1]National Institution for Medical Research, Dar es Salaam, Tanzania, United Republic of, [2]National Institution for Medical Research, Tanga, Tanzania, United Republic of, [3]National Malaria Control Program, Dodoma, Tanzania, United Republic of, [4]National Malaria Control Program, Dar es Salaam, Tanzania, United Republic of, [5]Malariologist and Public Health Specialist, Dar es Salaam, Tanzania, United Republic of, [6]World Health Organization, Country Office, Dar es Salaam, Tanzania, United Republic of, [7]Department of Pathology and Laboratory Medicine and Center for Computational Biology, Brown University, Providence, USA, RI, United States, [8]University of North Carolina, Chapel Hill, NC, United States, [9]Gothenburg University, Gothenburg, Sweden, [10]World Health Organization, Geneva, Switzerland

This study was conducted from April to September 2022 to assess efficacy and safety of artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ) for the treatment of uncomplicated falciparum malaria Tanzania due to reports of artemisinin partial resistance in Rwanda and Uganda. It was a single-arm prospective study that recruited 176 patients aged 6 months to 10 years who were treated with AL and ASAQ. Capillary sequencing was used to determine the prevalence of single nucleotide polymorphisms in Pf kelch 13 and multi-drug resistance 1 (mdr1) genes PCR corrected cure rates, safety of the two drugs, parasite clearance time and molecular makers of resistance in k-13 and mdr1 genes were assessed. PCR corrected adequate clinical and parasitological response (ACPR) for AL and ASAQ was 96.6% for AL and 100% for ASAQ. Among patients treated with AL and ASAQ; 11/88 (12.5%) and 17/88(19.3%) had parasitaemia beyond 72 hours, respectively. The slope half-life was <3.9hrs in both groups but it was significantly higher (>6.5hrs) in patients with day 3 parasitaemia and/or k-13 mutations at enrolment. In both groups, ≥23% of the patients had 561H mutations at enrolment. The day 3 patients with parasitaemia, 9.1% in AL and 11.4% in ASAQ had 561H mutations. The Mutations in k-13 gene were significantly associated with day 3 parasitaemia but they were not associated with recrudescent or recurrent infections in AL. Common adverse events reported were cough, runny nose, abdominal pain and fever; and not related to the study drugs. Confirmed artemisinin partial resistance, high cure rates and adequate safety were observed with 96.6% ACPR for AL and 100% for ASAQ. Containment strategies are urgently needed to prevent mutated parasites from spreading to other parts of the region and the entire country. 1

A RAPID DECLINING OF MULTIDRUG RESISTANT KEL1/PLA1 PLASMODIUM FALCIPARUM PARASITE IN VIETNAM DURING 2020-2022, A RESULT OF DRUG POLICY CHANGE

Thuy-Nhien Nguyen[1], Huynh Hong Quang[2], Tuyen Nguyen[1], Nhat Tran[1], Olivo Miotto[3]

[1]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [2]Institute of Malariology, Parasitology and Entomology -Quy Nhon, Binh Dinh, Viet Nam, [3]Mahidol Oxford Research Unit and Oxford University, Bangkok, Thailand

Genetic surveillance has been proved as a useful tool to monitor drug resistance and provided support evidences for the National Malaria Control Programs in decision making including drug policy change. In collaboration with the Vietnam NMCPs, genetic surveillance has been conducted in twelve malaria endemic provinces located in Central Highland and Southern of Vietnam since 2017. Our continuous results from six years surveillance have timely informed and alarmed the NMCPs about the efficacy of current first-line treatment and joined supported the change of National Treatment Guideline in 2020 in areas confirmed multi drug-resistant malaria (including Binh Phuoc, Dak Nong, Dak Lak, Gia Lai, Phu Yen provinces). Over 400 Plasmodium falciparum samples have been collected in those provinces during 2020-2022. The parasites have been genotyped follow transfered Amplicon Sequencing procedure from Welcome Sanger Institute and GenRe Mekong project. Our preliminary results show a declining of multidrug resistance KEL1/PLA1 P. falciparum parasites after national drug policy changed. The P. falciparum parasites carried C580Y Kelch13 mutation without associated piperaquine and mefloquine resistance (evidenced by amplification in the plasmepsin2/3 and pfmdr1 genes), has been gradually predominant in those malaria provinces. This indicated that the reversal back to a single plasmepsin2/3 genotype was the result of the change in first line therapy away from dihydroartemisinin-piperaquine in Vietnam.

5762

ASSOCIATIONS BETWEEN SULFADOXINE-PYRIMETHAMINE+AMODIAQUINE CONCENTRATIONS, MALARIA INCIDENCE, AND RESISTANCE MARKERS IN CHILDREN RECEIVING SEASONAL MALARIA CHEMOPREVENTION IN BURKINA FASO

Issaka Zongo[1], Alassane Haro[1], **Michelle E. Roh**[2], Romaric Oscar Zerbo[1], Liusheng Huang[3], Aristide Sawadogo[1], Jennifer Legac[4], Anyirékun Fabrice Somé[1], Rakiswendé Serge Yerbanga[1], Erika Wallender[3], Francesca Aweeka[3], Jean-Bosco Ouédraogo[5], Philip J. Rosenthal[4]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, United States, [3]Department of Clinical Pharmacy, University of California, San Francisco, San Francisco, CA, United States, [4]Department of Medicine, University of California, San Francisco, San Francisco, CA, United States, [5]Institut des Sciences et Techniques, Bobo-Dioulasso, Burkina Faso

Seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine+amodiaquine (SP-AQ) is given monthly during the transmission season to prevent childhood malaria in the sub-Sahel region of Africa. Optimal SP-AQ concentrations to confer protection against malaria and prevent selection of SP-AQ resistance are unknown. We conducted a prospective cohort study of children in Sourkoudougou, Burkina Faso 3-59 months old and eligible to receive SMC. 89% of the children were enrolled prior to the first SMC cycle, and all were followed longitudinally through the malaria transmission season (July to November, 2022). SMC was administered in four cycles: July 9-12, August 7-10, September 5-8, and October 4-7. Plasma levels of sulfadoxine, pyrimethamine, amodiaquine and its metabolite desethylamodiaquine were collected on days 7 and 28 following SMC administration and additionally on days 3 and 14 in a sub-cohort of 57 children for whom all three doses of SMC were directly observed. Incidence of malaria infection was assessed during routine and unscheduled clinic visits by blood smear. Dried blood samples were collected for assessment of genotypes. Among the 178 children enrolled, 103 incident malaria infections were recorded (incidence rate = 1.82 episodes per person-years). Across SMC cycles, malaria infection incidence was highest at four weeks after SMC administration (just before the next SMC cycle). Mean parasite prevalence was 5.9% [range: 4.0%-8.3%] on day 7 and 8.1% [range: 4.8%-10.8%] on day 28 after treatment. Compared to the full cohort, parasite prevalence was significantly lower among participants of the sub-cohort (whose SMC regimens were directly observed) on day 7 (1.9% [range: 0%-3.9%]; p=0.001), but not on day 28 (5.8% [range: 0%-9.1%]; p=0.09). Assessments of SP-AQ drug levels and drug resistance genotypes are ongoing. With these data we will perform population pharmacokinetic/pharmacodynamic modelling to characterize associations between drug exposure, malaria infection incidence, and drug resistance selection.

5763

POTENTIAL SUITABILITY OF SULFADOXINE-PYRIMETHAMINE PLUS AMODIAQUINE FOR SEASONAL MALARIA CHEMOPREVENTION IN AREAS OF HIGH, PRE-EXISTING DRUG RESISTANCE

Gina Maria Cuomo-Dannenburg[1], Andria Mousa[2], Sam Gudoi[3], Kevin Baker[3], Maria Suau Sans[3], Chuks Nnaji[3], John Baptist Bwanika[3], Ivan Alejandro Pulido Tarquino[3], Christian Rassi[3], Monica A. de Cola[1], Craig Bonnington[3], Robert Verity[1], Matthew Cairns[2], Paul Milligan[2], Cally Roper[2], Lucy Okell[1], Patrick G T Walker[1]

[1]Imperial College London, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention (SMC) targets the burden of malaria in children under five in areas of seasonal malaria transmission. Previously, the WHO recommended SMC only in the Sahel region which has low levels of sulfadoxine-pyrimethamine (SP) drug resistance, one of the drugs used for the intervention. However, in 2022 geographic restrictions were removed from WHO guidelines prompting new countries to consider SMC as a possible intervention. There is a need to understand whether SP-AQ would still be effective in areas with high SP resistance to guide the scale-up of SMC to new geographies. Here, we utilize data from the first randomized controlled trials of SMC outside of the Sahel region to estimate the protection provided by SMC which demonstrated a day 28 protective efficacy of 77%, even in areas with established high-level SP resistance. We use Bayesian inference methods to estimate the probability that SMC using SP-AQ would prevent an infection given time since drug administration, seasonality, baseline transmission and existing frequency of SP-resistance conferring mutations. We are currently using these results within an existing, extensively validated individual-based Plasmodium falciparum transmission model to estimate the potential impact of implementing SMC under a variety of scenarios, including exploring the number of cycles, their timing, and the suitable age range. Initial results suggest that in an area with 64.7% of clinical cases in 4 months and established dhfr-dhps quintuple mutation, SMC using four cycles of SP-AQ could prevent 51.1% (95% CI: 37.0 - 65.2%) of annual clinical P. falciparum cases in children under five years. Despite the high drug resistance already present in east and southern Africa, we predict that SMC has the potential to be a highly effective malaria intervention and could help avert some of the substantial malaria burden in young children in these geographies. It will be important to consider the impact of scaling up SMC on driving resistance to SP and AQ in areas where SP resistance is already relatively high.

5764

WUCHERERIA BANCROFTI MICROFILARIAE POSITIVE INDIVIDUALS SHOW AN INCREASED HUMAN IMMUNODEFICIENCY VIRUS INCIDENCE IN A GENERAL POPULATION STUDY IN SOUTHWEST TANZANIA

Jonathan L. Mnkai[1], Manuel Ritter[2], Lucas Maganga[1], Leonard Maboko[3], Willyhelmina Olomi[1], Agola Eric Lelo[4], Daniel Kariuki[5], Alexander Yaw Debrah[6], Christof Geldmacher[7], Michael Hoelscher[7], Elmar Saathoff[7], Mkunde Chachage[1], Kenneth Pfarr[2], Achim Hoerauf[2], Inge Kroidl[7]

[1]National Institute for Medical Research, Mbeya Medical Research Centre (NIMR-MMRC), Mbeya, Tanzania, United Republic of, [2]Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn (UKB), 53127, Bonn, Germany, [3]Tanzania Commission for AIDS, Dar es Salaam, Tanzania, United Republic of, [4]Kenya Medical Research Institute (KEMRI), KNH, Nairobi, Kenya, [5]College of Health Sciences, Jomo Kenyatta University of Agriculture and Technology (JKUAT), Nairobi, Kenya, [6]Kumasi Centre for Collaborative Research (KCCR), Kwame Nkrumah University of Science and Technology, UPO, PMB, Kumasi, Ghana, [7]Division of Infectious Diseases and Tropical Medicine, University Hospital of the University of Munich (LMU), 80802, Munich, Germany

As part of a large prospective general population study, our group had described a 2.3-fold increase in HIV incidence among individuals with Wuchereria bancrofti infection, as measured by the circulating filarial antigen of the adult worm. However, during the first study no night-blood was collected, which is essential for measuring of microfilariae (MF) of W. bancrofti was taken, because the focus of this activity was on soil-transmitted helminths and malaria. A new study presented here aimed to retrospectively determine the microfilariae status of the participants to reveal whether the increased HIV susceptibility previously described was associated with patent (MF-positive) or latent (MF-negative) filarial infection. Circulating filarial antigen(CFA)-positive biobanked human blood samples (n = 350) were analysed for W. bancrofti MF chitinase by real time PCR. The PCR provided a positive signal in 12/350 (3.4%) samples. During the four-years of follow-up period (1109 person years (PY)), 22 study participants acquired HIV infection. Three new HIV infections occurred in 39 PY of W. bancrofti MF chitinase positive individuals (7.8 cases per 100 PY), in contrast to 19 seroconversions in 1070 PY of W. bancrofti MF chitinase negative individuals (1.8 cases per 100 PY, p = 0.014). Immunomodulation induced by W. bancrofti appears to be more pronounced in microfilariae-positive individuals, as the HIV incidence observed in this subgroup

exceeded the moderately increased HIV risk previously described in all individuals with W. bancrofti (regardless of MF status) compared with uninfected persons from the same area.

DEVELOPING THE NATURAL PRODUCT CORALLOPYRONIN A TO TREAT FILARIASIS, STIS AND STAPHYLOCOCCI

Kenneth Pfarr[1], Andrea Schiefer[1], William Shafer[2], Jennifer Edwards[3], Tim Becker[1], Gabriele Bierbaum[1], Stefan Kehraus[4], Miriam Grosse[5], Alexandra Ehrens[1], Tanja Schneider[4], Katharina Rox[5], Marc P. Hübner[1], Karl G. Wagner[4], Thomas Hesterkamp[6], Marc Stadler[5], Achim Hoerauf[1]

[1]University Hospital Bonn, Bonn, Germany, [2]Emory Univeristy, Atlanta, GA, United States, [3]Nationwide Children's Hospital, Columbus, OH, United States, [4]University of Bonn, Bonn, Germany, [5]Helmholtz Centre for Infection Research, Braunschweig, Germany, [6]German Center for Infection Research, Braunschweig, Germany

Corallopyronin A (CorA) inhibits bacterial DNA-dependent RNA polymerase at a different binding site to rifampicin. Thus, it kills rifampicin-resistant Staphylococcus aureus. CorA also kills Gram-negative Wolbachia endobacteria of filarial nematodes that cause onchocerciasis (river blindness) and lymphatic filariasis (elephantiasis). Depleting the essential endosymbionts causes worm sterility and slow adult worm killing. We demonstrated CorA activity against Neisseria gonorrhoeae and multi-resistant S. aureus. At 4x MIC no CorA resistant N. gonorrhoeae could be selected (predicted frequency of mutation of ≤10-10). CorA also has activity against established S. aureus biofilms and prevent their formation. With its excellent biodistribution into bone, we have received funding to investigate CorA as a new antibiotic class to treat osteomyelitis and S. aureus biofilms. To develop CorA as a novel solution to several targets of the WHO Priority Pathogen List for which new antibiotics are needed, we conducted standard non-GLP ADMET studies. In-vitro toxicity tests (off-target, AMES, micronucleus, hERG, phototoxicity) demonstrated that it is non-toxic and pharmacologically safe; in vivo toxicity studies in rats and dogs measured a maximal tolerated dose (MTD) in both species of 1000 mg/kg. Seven-day repeated dose studies in rats and dogs demonstrated no prohibitive safety issues: predicted NOAEL=150 mg/kg/d; predicted HED=4 mg/kg. CorA drug substance is heterologously produced in genetically modified Myxococcus xanthus. Up-scale to industrial scale (15m3) was achieved in 2022 at Bio Base Europe Pilot Plant (Belgium). The Helmholtz Centre for Infection Research purified this large amount of material, achieving 90-95% pure HQ-RGM material. With amorphous solid dispersion formulation principles, two solid oral formulations were developed that increased stability (>3 months at 30 °C, >6 months at 5 °C) and oral bioavailability (mouse >59%, dog>53%) compared to neat CorA. We are establishing drug product production at GMP facilities. After finalization of the pre-clinical work, we plan to enter the clinical phase I in 2025/2026.

5766

ANIMALS AS RESERVOIR OF BRUGIA MALAYI IN BELITUNG DISTRICT, INDONESIA, AS A POTENTIAL THREAD FOR THE ELIMINATION OF LYMPHATIC FILARIASIS IN HUMANS

Taniawati Supali[1], I Made Suhermanta[2], Peter U. Fischer[3]

[1]University of Indonesia, Jakarta, Indonesia, [2]District Health Office, Belitung, Indonesia, [3]Washington University School of Medicine, St. Louis, MO, United States

In Indonesia, Brugia malayi is the most common filarial parasite in Sumatra, Kalimantan, Sulawesi, and adjacent islands. B. malayi occurs in two ecotypes; the zoophilic type that infects both humans and animals, and the anthropophilic type that is only found in humans. Belitung district was known to be endemic for zoophilic B. malayi but received 5 rounds of mass drug administration (MDA) with DEC and albendazole between 2006 and 2010 at high coverage, passed 3 transmission assessment surveys (TAS) and was assumed to be free of infection in 2017. In 2021 a surveillance survey in 7 villages found that 5 villages were endemic for B. malayi with an average microfilaria (Mf) rate of 2.1% (40/1910 adults). Mf positive subjects were treated using ivermectin, DEC and albendazole, and a more extensive survey in the entire district was performed in 2022 that found an average Mf rate of 1.3% (87/6898 participants). There are several reasons that could explain the presence of B. malayi despite of MDA and passed TAS. For example, TAS is based on schoolchildren, and may not detect ongoing transmission in adults or an animal reservoir could be responsible for reintroduction of parasites into the human population. To test the later hypothesis, we collected blood from 291 cats and 41 dogs in villages where Mf positive humans were found. Microscopic examination found B. malayi Mf in 3 dogs and 4 cats, most of them from a single village. Dirofilaria immitis was found in 13 dogs while Brugia pahangi was found in 11 cats and 3 dogs. Screening of monkeys is still ongoing, but Mf have been found in 6 of 28 macaques. Molecular species confirmation by qPCR and whole genome sequencing of B. malayi Mf for population genomics is currently underway. Results showed that in Belitung B. malayi is present in animals and could be the source for its reintroduction into the human population. Further studies have to demonstrate gene flow between the B. malayi populations in animals and humans to confirm the role of an animal reservoir. For the elimination of lymphatic filariasis, B. malayi areas with an animal reservoir may need to be declared as special zones with intensified intervention and surveillance.

SPATIAL ANALYSIS OF THE RELATIONSHIP OF ONCHOCERCA VOLVULUS EXPOSURE BETWEEN HUMANS AND BLACK FLIES IN ETHIOPIA

Caitlin Duffy[1], Emily Griswold[2], Fikresilasie Samuel[3], Fikre Seife[4], Sindew Mekasha[5], Zerihun Tadesse[3], Frank O. Richards[2], Gregory S. Noland[2], Jenna E. Coalson[2]

[1]Emory University, Atlanta, GA, United States, [2]The Carter Center, Atlanta, GA, United States, [3]The Carter Center, Addis Ababa, Ethiopia, [4]Federal Ministry of Health, Addis Ababa, Ethiopia, [5]Ethiopia Public Health Institute, Addis Ababa, Ethiopia

Onchocerciasis is a parasitic disease caused by Onchocerca volvulus that spreads through the bite of infectious Simulium flies, which breed in rapidly flowing rivers. Ethiopia has one of the highest burdens of onchocerciasis worldwide. Two key indicators of impact are Ov16 antibody prevalence in children, detected in dried blood spots (DBS) by ELISA, and the presence of infectious O. volvulus larvae in flies, detected through O-150 PCR. However, the quantitative relationship between the measures and their degree of spatial dependence is unclear. We explored associations between O-150-positive pools of flies and the prevalence of human antibodies to Ov16 in temporally and spatially proximal samples. The relationship was explored among villages in 8 zones in southern Ethiopia where S. damnosum sl is the principal vector. Data include DBS from 907 villages with data from 2022, and flies from 22 sites collected from 2021-2022. The study areas had received 4-20 years of ivermectin treatment by then. Clustering of residuals from an intercept-only log-binomial model of DBS locations was assessed using Moran's I and global colocation quotient, and the impact on spatial autocorrelation was measured after adding a covariate for O-150 fly pool positivity at the nearest breeding site within a threshold distance. Threshold distances were tested at 64km, 33km, 20km, and 10km according to the literature and common practice in the program. Results suggested that the relationship between nearby fly site positivity and village parasite exposure may be significant if the fly site is within 33km, with the association growing stronger as the threshold distance decreases. However, estimate precision became weaker as the threshold lowered due to data sparsity. Similarly, examination of residual spatial autocorrelation showed that incorporating fly site positivity to the model began to lower residual clustering at the 33km threshold. These findings will direct the collection and testing of flies to better elucidate the relationship between parasite prevalence in flies and humans across diverse geographies, informing cost-effective surveillance.

Mapping is a prerequisite for determining onchocerciasis endemicity and the need for interventions to eliminate transmission. Ethiopia has made nationwide mapping part of its elimination strategy. National guidelines were developed in 2015, in which a woreda (district), the implementation unit in Ethiopia, was considered endemic if the mean Ov16 antibody prevalence in 300 adults (100 from each of three villages) was ≥2%. In 2017, the Onchocerciasis Technical Advisory Subgroup (OTS) of the World Health Organization proposed sampling 500 adults in 5 communities and commencing mass drug administration (MDA) in an implementation unit if Ov16 prevalence in at least one community was ≥2%. Ethiopia embarked on mapping the 671 previously untreated districts between 2015 and 2019 using a combination of entomological and Ov16-serology studies, prioritizing areas adjacent to those already under treatment. Desk review was used first to exclude areas ecologically unsuitable for supporting vector flies and thus O. volvulus transmission. Next, entomologists prospected river systems during the rainy season to confirm these exclusions and to identify a minimum of three first-line communities near suitable vector breeding sites. Investigators excluded 181 districts based on unsuitable ecological conditions for vector breeding; dried blood spot (DBS) sampling was performed in the remaining 490 districts. To date, ELISA analysis for Ov16 has been analyzed for 122,405 DBS from 427 districts. Of these, 53 districts (12.4%) are considered endemic and in need of MDA by Ethiopia's guidelines. An additional 102 districts (23.9%), encompassing 15 million people, would be considered endemic by OTS guidelines. This discrepancy has dramatic resource (cost and labor) implications. We recommend further investigation to determine if OTS thresholds reliably identify district-wide transmission.

MONITORING IMPACT OF THREE ROUNDS OF MASS DRUG ADMINISTRATION IN EIGHT HIGH-RISK VILLAGES USING A THREE-DRUG REGIMEN ON LYMPHATIC FILARIASIS IN AMERICAN SAMOA

Tara A. Brant[1], Aifili Tufa[2], Fara Utu[2], Noelle Tavale[2], Lynette Suiaunoa-Scanlan[3], Ula Pele[3], Maopa Lewabeci[2], Benjamin Sili[2], Emily A. Dodd[1], Hong Zhou[1], Janet M. Camacho[4], Emi Chutaro[4], Kimberly Y. Won[1], Motusa T. Nua[2]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]American Samoa Department of Health, Pago Pago, American Samoa, [3]Pacific Island Health Officers' Association, Pago Pago, American Samoa, [4]Pacific Island Health Officers' Association, Honolulu, HI, United States

In 2018, 2019 and 2021, the American Samoa Department of Health (DOH) conducted mass drug administration (MDA) for lymphatic filariasis (LF) with ivermectin, diethylcarbamazine and albendazole (IDA) and conducted impact surveys after each MDA. COVID-19 prevented MDA in 2020. Post-MDA 1, circulating filarial antigen (CFA) and microfilariae (Mf) prevalence in 8 high-risk villages (defined as having ≥3 CFA positive and/or ≥1 Mf positive people in 2019) were 4.3% (95% confidence interval (CI) 2.8-6.4) and 1.3% (95% CI 0.6-2.6), respectively. In 2020, CFA prevalence was 2.0% (95% CI 1.2-3.0) and Mf was 1.1% (95% CI 0.5-2.1). MDA coverage was 78.3% (MDA 1) and 90.1% (MDA 2). In Sep-Oct 2022, DOH sampled 550 people (≥5 years) in the 8 high-risk villages using a sampling strategy based on history of LF and village size. We asked about participation in all 3 MDAs and fingerstick blood samples were screened for CFA; CFA positive persons were tested for Mf and offered IDA. Mf positive persons were examined 7 days after treatment for Mf clearance. We weighted analyses based on the proportion of sampled data over village population. Mean CFA and Mf prevalence in 2022 were 2.2% (95% CI 0.7-3.6) and 0.1% (95% CI 0.0-0.1), respectively. Of participants, 83.4% (95% CI 69.2-97.5) reported taking the medicines in MDA 3, and 76.2% (95% CI 61.6-90.7) participated in all 3 MDAs. Of the 48 CFA positive persons, 64.0% (95% CI 0.1-1.9) were male and most were aged 20-39 years (49.4%; 95% CI 0.1-3.8); 90.1% (95% CI 0.1-1.3) reported swallowing pills in MDA 3. Eight (9.9%) reported never participating in MDA; 7/8 were male (mean age 52.9 years). The 2 Mf positive persons were both males aged 59 years, neither reporting ever taking the medicines. DOH followed up and treated 46/48 CFA positive persons, including the 8 never treated. High MDA coverage (≥65%) and a low proportion of never treated led to a decline in Mf prevalence in the defined villages. Despite Mf prevalence meeting the stop MDA target (<0.5%), high CFA prevalence, vector efficiency and frequent movement between American Samoa and LF-endemic Samoa, supports the need for another MDA, including social mobilization targeting men.

RATE OF ONCHOCERCA VOLVULUS MICROFILARIAE IN NODULE CARRIERS IN VILLAGES UNDER MASS DRUG ADMINISTRATION IN FUAMAH DISTRICT, LIBERIA

Cooper Sannah[1], Abakar Gankpala[2], Nicole Fetcho[3], Lincoln Gankpala[2], Aaron T. Momolu[2], Edward B. Guizie[1], Bindu Taweh[1], Evon Vesselee[4], Kasor Kollie[5], Gary J. Weil[3], Peter U. Fischer[6], Patrick N. Kpanyen[1]

[1]National Public Health Institute of Liberia, Monrovia, Liberia, [2]National Public Health Institute of Liberia, Charlesville, Liberia, [3]Washington University School of Medicine, Saint Louis, MO, United States, [4]Family Health, Ministry of Health, Monrovia, Liberia, [5]NTD team, Ministry of Health, Monrovia, Liberia, [6]Washington University School of Medicine, St. Louis, MO, United States

Onchocerciasis or riverblindness is endemic in most parts of Liberia. In 2021 it was estimated that 3.24 million people required mass drug administration (MDA) with ivermectin to control and eliminate onchocerciasis, and it was reported that 2.3 million (71%) received treatment. Although the entire country is covered by MDA, the coverage rates vary considerably by area/clan. Fuamah district (Bong County) has a population of 56,000 belonging to 5 clans living along the St. Paul river. Before the civil war, the district was a successful mining community, but now the infrastructure has degraded, the population consists mostly of retired mining workers, and subsidence farmers and their families and villages are difficult to reach. Although the district receives annual MDA through the Neglected Tropical Disease Department of the Ministry of Health, onchocerciasis is still highly endemic with Onchocerca volvulus nodule carrier rates in adults of up to 40%. Simulium vector densities are high, but the prevalence of microfilariae (Mf) in the human reservoir is unknown. In order to estimate the prevalence of O. volvulus Mf in the human population and to determine whether the area is suitable for clinical trials to improve the treatment for onchocerciasis, we performed a survey in the entire district. We examined 888 adults (25% women) with palpable nodules by skin snip (2 snips from the iliac crest and 2 snips from the calf) 12 months after the last MDA. The prevalence of Mf in nodule carriers varied between clans from 4.9% to 49.4%. The sensitivity to detect Mf in snips taken from the iliac crest and the calf was similar (94.5%, mean 10 Mf/mg vs 94.3%, 9 Mf/mg, respectively). A total of 353 subjects with palpable nodules and a Mf density ≥3 Mf/mg suitable for a clinical trial were identified. Subjects were pretreated with ivermectin to clear Mf from the eye and to enable future trials with regimens that contain the drug DEC. These results show that despite widespread MDA, subjects with O. volvulus nodules and microfiladermia are still prevalent in Fuamah and clinical trials can be performed in the same communities that will later benefit from new treatment strategies.

Chan School of Public Health, Boston, MA, United States, [2]College of Osteopathic Medicine of the Pacific – Northwest, Western University of Health Sciences, Lebanon, OR, United States, [3]Center for Biotechnology Research and Development, Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [4]Department of Biology, Center for Evolutionary and Theoretical Immunology, Parasite Division Museum of Southwestern Biology, University of New Mexico, Albuquerque, NM, United States

Schistosomiasis is a chronic inflammatory disease afflicting hundreds of millions of people worldwide. Schistosomes are helminths transmitted by aquatic snails, and the disease can potentially be controlled by blocking transmission at the snail stage. Most cases of intestinal schistosomiasis occur in sub-Saharan Africa, where they are caused by Schistosoma mansoni, transmitted by the snail Biomphalaria sudanica and related species. In contrast to the better-studied neotropical vector B. glabrata, there has been little genomic work on these African snails and the genetic basis of snail-parasite interaction is completely unknown. Identifying snail genes that convey resistance to infection may facilitate ways to leverage these immune mechanisms and disrupt the parasite's life cycle. To uncover such immunogenetic pathways, we have generated an annotated genome assembly of B. sudanica and used it to support a genome-wide association study. We exposed F1 offspring of wild-caught Kenyan B. sudanica, originating from Lake Victoria, to S. mansoni and recorded infection status through cercarial shedding. Pools of infected (N = 493) and uninfected (N = 295) snails were then sequenced across the whole genome at a mean per-individual coverage of over 1x. We have identified several loci associated with infection status, including genomic regions known to influence parasite resistance in B. glabrata as well as previously uncharacterized genes. These results provide a first glimpse into genes of the innate immune system of the major vector B. sudanica and will help inform schistosomiasis control strategies aimed at predicting or manipulating the vector competence of the snail host, particularly in the African communities most severely affected by this disease.

Transmission of the carcinogenic trematode Opisthorchis viverrini is ongoing in Southeast Asia despite decades of control efforts. The resulting bile duct cancer (cholangiocarcinoma) is one of the leading causes of death in regions of Thailand, Lao PDR and Cambodia. Developing evidence-based programs for control require a mechanistic understanding of parasite transmission, however there are several unresolved epidemiological questions including the extent of parasite migration between neighboring countries and whether animals, primarily domestic cats, act as reservoir hosts. To address these knowledge gaps and to stimulate further research into the molecular epidemiology of O. viverrini, we present an improved reference genome which incorporates long read sequencing to give chromosome-level resolution. We then developed methodologies to whole-genome sequence adult worm and egg stages of flukes isolated from infected individuals to understand the pattern of genetic variation in natural parasite populations. Finally we sequenced O. viverrini from Thailand and Lao PDR and compared sequence data between human and animal infective parasites to determine the relatedness between populations and the extent of zoonotic transmission. Our study provides an unprecedented understanding of the molecular epidemiology underlying the transmission of a medically significant, yet highly neglected, human parasite.

5773

TEST-TREAT-TRACK-TEST-TREAT (5T) APPROACH FOR BREAKING SCHISTOSOMIASIS TRANSMISSION

Lydia Trippler[1], Lyndsay Taylor[1], Mohammed N. Ali[2], Jan Hattendorf[1], Saleh Juma[3], Fatma Kabole[4], Said M. Ali[2], Stefanie Knopp[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Public Health Laboratory - Ivo de Carneri, Wawi, Chake Chake, Pemba, Tanzania, United Republic of, [3]Neglected Diseases Programme, Zanzibar Ministry of Health, Mkoroshoni, Pemba, Tanzania, United Republic of, [4]Neglected Diseases Program, Zanzibar Ministry of Health, Lumumba, Unguja, Tanzania, United Republic of

The World Health Organization has set the goal to eliminate schistosomiasis as a public health problem worldwide by 2030. Pemba Island, Tanzania, achieved this goal in 2017 and is now aiming for interruption of transmission. In most parts of Pemba, the Schistosoma haematobium prevalence is below 3% and mass drug administration of praziquantel no longer seems justified. As an alternative, we investigate a test-treat-track-test-treat (5T) approach to prevent recrudescence and accelerate elimination. In the 4-year SchistoBreak project implemented in two districts in the North of Pemba, schoolchildren are screened for microhematuria as a proxy for S. haematobium infection at the point-of-care. Positive children are treated with praziquantel and tracked to their homes and the waterbodies they use. Test-and-treat is offered to household members and people present at waterbodies. Additionally, urine samples are examined for S. haematobium eggs by urine filtration. Annual cross-sectional school- and household-surveys are conducted to monitor the prevalence and impact of the intervention. In 2021, 5.5% (239/4347) of the children screened in schools were microhematuria-positive and tracked to 199 households. Among their household members, 21.3% (60/282) were microhematuria-positive and 11.0% (31/282) egg-positive. At 77 waterbodies, 22.4% (30/134) of individuals tested microhematuria-positive and 4.5% (6/134) were egg-positive. The cross-sectional surveys in schools revealed a microhematuria prevalence of 2.4% (47/1933) in 2021 and of 6.3% (111/1767) in 2022. In households, the microhematuria prevalence was 5.6% (162/2972) in 2021 and 13.2% (387/2921) in 2022; the S. haematobium prevalence was 0.5% (14/2971) in 2021 and 0.6% (19/2929) in 2022. Our results show that 5T is an excellent approach to identify and treat individuals with urogenital schistosomiasis in low-prevalence areas. While microhematuria levels increased from 2021 to 2022, the S. haematobium prevalence remained stable. Future study years will confirm if 5T is indeed a suitable intervention to maintain current gains or to accelerate interruption of transmission.

5774

CHARACTERIZATION AND PROCESS DEVELOPMENT OF SERINE PROTEASE INHIBITOR: A NEXT GENERATION TRANSMISSION-BLOCKING VETERINARY MRNA VACCINE FOR ASIATIC SCHISTOSOMIASIS

Adebayo J. Molehin[1], Brooke Hall[1], Christine Lee[1], Sean A. Gray[2], Darrick Carter[2]

[1]Midwestern University, Glendale, AZ, United States, [2]PAI Life Sciences Inc, Seattle, WA, United States

Asiatic schistosomiasis caused by Schistosoma japonicum is a neglected tropical disease resulting in significant morbidity to both humans and animals - particularly bovines - in endemic areas. Infection with this parasite leads to less healthy herds, causing problems in communities which rely on bovines for farming, milk and meat production. Additionally, excretion of parasite eggs in feces perpetuates the life cycle and can

lead to human infection. We endeavored to develop an inexpensive and effective mRNA vaccine based on secretory serine protease inhibitor (serpin) from S. japonicum (Sj-B6). In pathogens, serpins are believed to have evolved specifically to limit host immune responses by interfering with the host immune-stimulatory signals. Transcriptional profiling and proteomics demonstrated that Sj-B6 is expressed in the intra-mammalian life cycle stages but particularly in the eggs, suggesting a possible role in disease transmission. Recombinant Sj-B6 inhibited host pancreatic elastase in a dose-dependent manner and was strongly recognized by experimentally infected rat (naturally-resistant hosts) sera when compared to chronically-infected mouse counterparts, indicating that rSj-B6 is not only highly immunogenic, but critically involved in disease resistance. This study presents a comprehensive functional characterization of Sj-B6 supporting its further development as a vaccine candidate against Asiatic schistosomiasis. A pilot study evaluating the efficacy of a novel Sj-B6 mRNA vaccine using a proprietary technology (HDT-301) invented by our partners at HDT Bio is now underway. The HDT-301 platform consists of a self-replicating RNA (repRNA) adsorbed and stabilized on a Lipid InOrganic Nanoparticle (LION™) carrier. The repRNA/ LION™ vaccine stabilizes the RNA in vivo allowing it to persist longer. A successful veterinary vaccine would play a major role in reducing pathogen transmission to humans by interrupting the parasite life cycle and improving quality of life for people living in endemic countries.

5775

SCHISTOSOMA JAPONICUM CHALLENGE INFECTION MODEL IN CARABAOS (PHILIPPINE WATER BUFFALO) FOR THE PLACEBO-CONTROLLED TRIAL OF THE SJ97 AND SJ68 VACCINE CANDIDATES

Mario L. Jiz[1], Daria L. Manalo[1], John Ezra David dela Cruz[1], Joseph Valencia[1], Sarah Li[2], Jonathan D. Kurtis[3], Hannah W. Wu[3]

[1]Research Institute for Tropical Medicine, Muntinlupa City, Philippines, [2]Biomedical Research Institute, Rockville, MD, United States, [3]Warren Alpert Medical School at Brown University, Providence, RI, United States

Schistosomiasis japonica is a zoonosis that persists as a public health problem in Asia particularly the Philippines, where hotspots remain despite decades of mass drug administration. Novel interventions such as vaccines are warranted to control the infection sustainably. Schistosoma japonicum infects over 40 mammals, with water buffalos as major animal reservoirs. We reported the development of an S. japonicum challenge model in carabao (native Philippine water buffalo) to evaluate vaccine candidates. Locally collected snails from endemic areas in Leyte were initially used as the source of cercaria. However, the perfused worm count is much lower than in our previous vaccine-challenge experiments in China, with a mean patency of 2.6%. The carabaos require a four-fold higher infectious dose, necessitating laboratory-reared snails. Weekly trickle infections in juvenile carabaos produced the highest yields upon sacrifice and worm enumeration by perfusion. To demonstrate the utility of the carabao challenge model, we conducted a placebo-controlled trial of the Sj97 and Sj97+Sj68 vaccine adjuvanted in ISA206. Carabaos (N=8 per group) were vaccinated with 3 doses of 500 ug Sj97, Sj97+Sj68, or saline placebo, adjuvanted with ISA206, and administered subcutaneously every 4 weeks. A half-dose booster was given 3 months after the last dose due to pandemic-associated delays. Vaccination induced robust antigen-specific IgG1, IgG2, total IgG responses, and Sj97-specific IFN gamma. Trickle infection with 2,000 S. japonicum cercaria yielded a mean of 251.8 in the adjuvant ISA206-only group upon perfusion 8 weeks post-infection. Carabaos in the Sj97+Sj68 vaccinated group had lower worm burdens than the placebo. Due to the significant variance in worm counts, the 40-70% protection by vaccination didn't reach statistical significance (Mann-Whitney test, p=0.6 for rSj97-rSj68 vs. ISA206; p= 0.5 for rSj97 vs. ISA206). We expect to report on the larger placebo-controlled Sj97+Sj68 vaccine trial with N=20 carabaos per group in the near future.

5776

TWO KEY ACTINOBACTERIA GENERA BIFIDOBACTERIUM AND COLLINSELLA IN THE HUMAN GUT MICROBIOTA ARE DIFFERENTIALLY ASSOCIATED WITH SCHISTOSOMA MANSONI INFECTION BURDEN

Francis Ankomah Appiah-Twum[1], Jewelna Akorli[1], Lydia Okyere[2], Hilda Darko[1], Michael Wilson[1]

[1]Noguchi Memorial Institute For Medical Research, Legon, Accra, Ghana, [2]University of Illinois Urbana-Champaign, Chicago, IL, United States

Among the soil-transmitted helminths schistosomiasis is the least amenable to control due to the ease of reinfection and the difficulty of administration of praziquantel en masse, due to its side effects. The overall goal of the study was to identify the key microbial taxa associated with human gut dysbiosis during Schistosoma mansoni infection and to obtain orthologs information that could form the basis for an alternate schistosomiasis control development. Twenty schistosomiasis positives stool samples and an equal number of age-sex matched negatives from a -endemic rural community, Nyive, in Ghana were studied. The Kato-Katz method was used and the infection intensity scored as egg count per gram (e.p.g.) and positive stool samples further stratified as surrogates of chronic (<400 e.p.g., n=15) and acute (>400 e.p.g., n=5) infections. The composition and biodiversity of the gut microbiota and potential biomarkers associated with S. mansoni infection intensity were determined from 16S rRNA amplicon sequencing method and QIIME2 analytical software. A significant increase in Beta diversity (a measure of similarity) seen in the positives compared to the negatives (ANOSIM R = 0.06, p = 0.0386). There was a significant increased abundance of Bifidobacterium among chronic cases (p = 0.0025), whilst Collinsella was significantly elevated in acute infection samples (p = 0.039). The pathobionts Escherichia-Shigella was significantly reduced in the acute cases (p = 0.027). The KEGG pathway analysis revealed significant enrichment of 31 significant orthologs (p < 0.001, False Discovery Rate (FDR) < 10%) in positive samples. Bifidobacterium is a known probiotic shown to reduce malaria intensity in mice and the identified orthologs would enable exploitation for drug discovery.

5777

PREVALENCE AND DISTRIBUTION OF FEMALE GENITAL SCHISTOSOMIASIS ACROSS THREE ENDEMIC COUNTRIES, TIMELINE, AND AGE GROUPS

Navneet Kaur, **Nilanjan Lodh**

Marquette University, Milwaukee, WI, United States

Schistosomiasis is the world's second-deadliest parasitic disease, affecting 220 million people and causing approximately 200,000 deaths. It is caused by a trematode parasite of the genus Schistosoma, three species of which frequently infect humans: Schistosoma japonicum, S. haematobium, and S. mansoni. Female Genital Schistosomiasis (FGS) is caused by S. haematobium and is predominant in young girls between 12-15 years old. In Lower Middle-Income Countries (LMIC), like Zambia, Ghana, and Tanzania where schistosomiasis is endemic, knowledge regarding FGS is incomplete and often confused with other sexually transmitted diseases. FGS remains largely overlooked within the national health systems and Neglected Tropical Diseases (NTDs) programs, which causes a chronic gynecological condition that leads to substantial morbidity, infertility, cervical cancer, and syphilis disease. It modifies the immunological response to increasing the risk of contracting human papillomavirus (HPV), and human immunodeficiency virus (HIV). The objective of the study is to determine the prevalence of FGS based on the presence of parasite DNA and diagnostic tests in females across age groups from a database of field-acquired human samples from Zambia, Tanzania, and Ghana over multiple years. During the analysis for Ghana, 39 out of 90 samples were females of which 31 (79.5%) were positives and 8 (20.5%) were negatives. In Zambia (2016), 80 out of 133 samples were females of which 46 (57.5%) tested positive and 34 (42.5%) were negative. For Zambia 2017, 60 out of 110 samples were females of which 45 (75%) tested positive and 15 (25%) tested negative. In Tanzania, 70 out of 104 samples were females of which

43 (61.4%) tested positive and 27 (38.6%) tested negative. The outcome highlights that FGS is predominant among females in different endemic countries. This study will help determine and explore the burden of FGS to develop strategies to control FGS and improve current intervention measurements for Schistosomiasis.

5778

EFFICACY AND SAFETY OF BUTANTAN-DV LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE FROM A PHASE 3 CLINICAL TRIAL IN CHILDREN, ADOLESCENTS, AND ADULTS

Mauricio L. Nogueira[1], Monica A.T. Cintra[2], José A. Moreira[2], Elizabeth G. Patiño[2], Patricia Emilia Braga[2], Patricia S. Carneiro[2], Lucas B. Alves[2], Juliana C.V. Tenório[2], Vanessa Infante[2], Alejandra Esteves-Jaramillo[3], Tulin Shekar[3], Jung-Jin Lee[3], Julieta Macey[3], Sabrina Gozlan Kelner[3], Beth-Ann G. Coller[3], Fernanda Castro Boulos[2], Esper G. Kallás[4]

[1]Faculdade de Medicina de São José do Rio Preto (FAMERP), São José do Rio Preto, Brazil, [2]Instituto Butantan, Sao Paulo, Brazil, [3]Merck & Co., Inc., Rahway, NJ, United States, [4]Instituto Butantan/Hospital das Clinicas da Faculdade de Medicina da USP-SP, Sao Paulo, Brazil

Butantan-DV is a live-attenuated tetravalent dengue vaccine produced by Instituto Butantan. We assessed the efficacy and safety of Butantan-DV. Participants were stratified by age (2-6, 7-17, and 18-59 years old) and randomized 2:1 to receive a single dose of Butantan-DV or placebo in an ongoing, phase III, double-blind trial conducted in 16 sites across Brazil, with projected five years follow-up (NCT02406729). 16,235 participants were enrolled and received Butantan-DV (10,259) or placebo (5,976) between 2016 and 2019; 46.5% of participants were dengue-naïve. Safety was evaluated as the frequency of participants with solicited (local and systemic) vaccine-related adverse events (AEs). Vaccine efficacy (VE) to prevent symptomatic virologically confirmed dengue (VCD) by RT-PCR after Day 28 postvaccination to any dengue virus (DENV) serotype was determined. Secondary objectives, VE by baseline serostatus, serotype, age, and against severe disease/dengue with warning signs, regardless of hospitalization, were also evaluated. Non-serious, solicited systemic vaccine-related AEs were observed in a slightly higher proportion of overall participants receiving Butantan-DV (58.3%) compared to placebo (45.6%) within 21 days postvaccination. The proportion of participants with AEs within each age group was generally comparable to what was observed in the overall population. After two years of follow-up, the overall VE was 79.6% (95% CI:70.0%-86.3%) and was 80.1% (95% CI:66.0%-88.4%) in ages 2-6, 77.8% (95% CI:55.6.0%-89.6%) in ages 7-17, and 90.0% (95% CI 68.2%-97.5%) in ages 18-59. Serotype-specific VE was 89.5% (95% CI:78.7%-95.0%) against DENV1 and 69.6% (95% CI:50.8%-81.5%) against DENV2 in the overall population. Through the extended follow-up period, which included between 2-5 years of follow-up for all participants, there were no cases of DENV3 or DENV4 and VE against dengue with warning signs/severe dengue was 88.2% (95% CI: 50.8-98.2%). In summary, Butantan-DV was generally well tolerated and efficacious against DENV1 and DENV2 symptomatic VCD, regardless of dengue baseline serostatus or age, through the follow-up.

A PHASE 1 OPEN LABEL TRIAL ASSESSMENT OF A DENGUE HUMAN INFECTION MODEL USING A DENGUE VIRUS SEROTYPE 4 LIVE VIRUS CHALLENGE

Joel V. Chua[1], Angie Price[1], Salma Sharaf[1], Youngchae J. Yoo[1], Hernando Gutierrez-Barbosa[1], Kathleen A. Strauss[2], Sudhaunshu Joshi[2], Rafael A. De La Barrera[3], Heather L. Friberg[4], Michael A. Koren[4], Robert Edelman[2], Kirsten E. Lyke[2]

[1]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Pilot Bioproduction Facility, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue Human Infection Models (DHIM) are critically needed in dengue vaccine and pharmacologic development and can provide a tool for understanding viral-host immunology in a controlled setting. We conducted a phase 1 open labeled, dose-escalation study evaluating the safety and dose of an attenuated Dengue-4-Virus-Live Virus Human Challenge (DENV-4-LVHC) strain intended for DHIM studies. Ten healthy adult volunteers were challenged with a single subcutaneous dose (95 PFU) of DENV-4-LVHC strain H-241 and followed daily from Days 4-16 (or until RNAemia resolved) with quantitative PCR used for detection and solicited adverse events assessed. All ten volunteers developed detectable RNAemia with mean onset at 4.2 days (range of 4-6 days) and a mean duration of 8.7 days (range of 7-11 days). RNAemia peaked between Days 5-11 (mean 7.3 days) and ranged from 5.28 x 105 to 7.60 x 106 copies/µL. All ten volunteers developed symptoms consistent with self-limited, mild dengue infection. The most common symptoms were fatigue, rash, and headache. All developed a nonpruritic, nontender, morbilliform rash, of which 8/10 involved >50% of their body surface area. The majority of other dengue symptoms were mild to moderate, with one volunteer reporting transient grade 3 (severe) headache and fatigue/malaise. Three of 10 developed mild to moderate fevers (38.1-38.8 oC). Laboratory abnormalities were seen in 8 of 10 volunteers, most common being elevated AST and leukopenia - all spontaneously resolved by Day 28. None developed thrombocytopenia. No serious adverse events were observed, and dose escalation was not required. Compared to a previously optimized DENV-1-LVHC, DHIM-4 resulted in an earlier onset (mean 4.2 vs. 8.3 days, $p < 0.0001$), earlier peak (mean Day 7.3 vs. 13.0, $p < 0.0001$), and shorter duration (mean 8.7 vs. 13.0 days, $p = 0.0002$) of RNAemia. In addition, rashes were more prominent in DHIM-4 than in the previous DHIM-1. Our findings support the safety of low-dose DENV-4-LVHC, resulting in uncomplicated mild dengue infection, and is suitable for use in future DHIM evaluation for vaccine and therapeutic development.

SAFETY AND IMMUNOGENICITY OF A SYNTHETIC NANOPARTICLE-BASED, T CELL PRIMING PEPTIDE VACCINE AGAINST DENGUE IN HEALTHY ADULTS IN SWITZERLAND: A DOUBLE-BLIND, RANDOMIZED, VEHICLE-CONTROLLED, PHASE 1 STUDY

Alix Miauton[1], Régine Audran[2], Juliette Besson[1], Hélène Maby-El Hajjami[3], Maxime Karlen[1], Loane Warpelin-Decrausaz[4], Loredana Sene[3], Sylvain Schaufelberger[5], Vincent Faivre[5], Mohamed Faouzi[6], Mary-Anne Hartley[1], François Spertini[2], Blaise Genton[1]

[1]Tropical, travel and vaccination clinic, Center for primary care and public health (Unisanté), Lausanne, Switzerland, [2]Division of Immunology and Allergy, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland, [3]Clinical Trial Unit, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland, [4]Research support unit, Center for primary care and public health (Unisanté), Lausanne, Switzerland, [5]Information systems and digital transformation, Center for primary care and public health (Unisanté), Lausanne, Switzerland, [6]Biostatistics unit, Center for primary care and public health (Unisanté), Lausanne, Switzerland

Vaccine types other than current antibody-inducing ones are needed to address the global health threat posed by dengue. This study, the first of its kind, assessed the safety and immunogenicity of a CD8+ T cell priming, gold nanoparticle (GNP)-based, multi-valent, synthetic peptide dengue vaccine, designed to provide protective cellular immunity without inducing antibodies. In this randomized, double-blind, vehicle-controlled, phase 1 trial (NCT04935801), healthy individuals aged 18-45 years recruited at the Centre for primary care and public health, Lausanne, Switzerland, were randomly assigned to receive the vaccine candidate (PepGNP-Dengue) or a comparator (GNP without peptides [vehicle-GNP]). Randomization was stratified into four groups based on a risk-minimising dose-escalation strategy (low dose [LD] and high dose [HD], pioneers and followers), allocation was double-blind for participants and investigators. Two doses

were administered by intradermal microneedle injection 21 days apart. Primary outcome was safety, secondary outcome immunogenicity. 26 participants were enrolled (Aug–Sep 2021) to receive PepGNP-Dengue (LD or HD, n=10 each) or vehicle-GNP (LD or HD, n=3 each). No vaccine-related serious adverse events occurred. Most (90%) related adverse events were mild; injection site pain and transient discoloration were most frequently reported. Injection site erythema occurred in 58% of participants. As expected, PepGNP-Dengue did not elicit anti-DENV antibodies of significance. Significant increases were observed in specific CD8+ T cells and dengue dextramer+ memory cell subsets in the LD PepGNP-Dengue but not in the HD PepGNP-Dengue or Vehicle-GNP groups, specifically PepGNP-activated CD137+CD69+CD8+ T cells (day 90, p= 0·046), differentiated effector memory (TemRA) and central memory (Tcm) CD8+ T cells (day 35, p=0·014 and p=0·024, respectively). Results provide proof of concept that a synthetic nanoparticle-based peptide vaccine can successfully induce virus-specific CD8+ T cells. The favourable safety profile and cellular responses observed support further development of PepGNP-Dengue.

CHIKUNGUNYA VACCINE VLA1553 INDUCES CROSS-NEUTRALIZATION AGAINST DIFFERENT CHIKV GENOTYPES

Karin Kosulin[1], Trevor L. Brasel[2], Jeanon Smith[2], Maricela Torres[2], Annegret Bitzer[1], Katrin Dubischar[1], Vera Bürger[1], Scott C. Weaver[2], David WC Beasley[2], Romana Hochreiter[1]

[1]Valneva Austria GmbH, Vienna, Austria, [2]University of Texas Medical Branch, Galveston, TX, United States

Chikungunya virus (CHIKV) is a small spherical RNA virus and a member of the Alphavirus genus in the family Togaviridae. The virus is vectored by the daytime-biting Aedes aegypti and Ae. albopictus mosquitoes and spread in over 100 countries with more than 2.6 million suspected cases alone in the Americas since 2013. CHIKV is classified into three genotypes including the West African, the East-Central and South African (ESCA) and the Asian lineage. Currently, neither specific antiviral treatment nor a vaccine is available to prevent CHIKV infection. Valneva´s attenuated CHIKV single-dose vaccine candidate, VLA1553, comprises a large deletion in the non-structural replicase complex protein nsP3, which leads to attenuation of the virus in vivo. The vaccine is based on the La Reunion (LR) strain belonging to the Indian Ocean sublineage of the ECSA genotype. Cross-neutralization testing with other lineages is of importance to provide information on a broad neutralization activity by the vaccine. For this purpose, a panel of human sera (n=72) collected at day 1, 29, 85 or 180 from a phase 3 clinical study has been tested by a classical PRNT against wt CHIKV strains from different lineages. The tested strains include the La Reunion strain (LR2006_OPY-1) of the Indian Ocean/ECSA lineage, strain 37997 from the West African lineage and the Caribbean M109 strain from the Asian lineage. Neutralizing antibodies were detected against all three CHIKV strains in sera 28 days after a single dose of VLA1553. The PRNT50 titers of CHIKV baseline-negative participants increased on day 29, and sustained neutralization was measured on days 85, and 180 post-vaccination. The high titer vaccine sera reached neutralization titers comparable to convalescent sera (collected during outbreaks in Latin America 2015-2016) tested in the same PRNT against the various wt CHIKV strains. In summary, analysis of human serum from the phase 3 clinical trial of Valneva´s live-attenuated vaccine demonstrated a broad spectrum of neutralizing antibody activity against all major CHIKV genotypes.

5782

IMMUNOGENICITY OF AN EXTENDED DOSE INTERVAL FOR THE AD26.ZEBOV, MVA-BN-FILO PROPHYLACTIC EBOLA VIRUS VACCINE REGIMEN IN ADULTS AND CHILDREN IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Edward M. Choi[1], Hugo Kavunga-Membo[2], Kambale Kasonia[1], Daniel Mukadi-Bamuleka[2], Soumah Aboubacar[3], Zephyrin Mossoko[2], Tansy Edwards[1], Darius Tetsa-Tata[1], Grace Mambula[3], Daniela Manno[1], Chelsea McLean[4], Babajide Keshinro[4], Auguste Gaddah[5], Cynthia Robinson[4], Kerstin Luhn[4], Nathalie Imbault[6], Rebecca Grais[3], Daniel G. Bausch[1], Deborah Watson-Jones[1], Jean-Jacques Muyembe[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Institut National de Recherche Biomédicale, Kinshasa, Congo, Democratic Republic of the, [3]Epicentre, Paris, France, [4]Janssen Vaccines and Prevention B.V., Leiden, Netherlands, [5]Janssen Research & Development, Beerse, Belgium, [6]Coalition for Epidemic Preparedness Innovations, Oslo, Norway

During the 2018-2020 Ebola virus disease (EVD) epidemic in north-eastern Democratic Republic of the Congo, we undertook a large, population-based Phase 3 trial of the two-dose Ad26.ZEBOV, MVA-BN-Filo vaccine regimen in healthy participants aged ≥1 year in Goma (Protocol DRC-EB-001; NCT04152486). However, all face-to-face activities were suspended five months into the study due to the COVID-19 pandemic, resuming five months later. As a result, 6,043 out of 20,408 participants received dose 2 outside the recommended 56-day (-14/+28 days) window. We reconsented adults (≥18 years), adolescents (12-17 years), and children (4-11 years) who received dose 1 but not dose 2 and returned after the study suspension and enrolled them into an immunogenicity subset to assess the impact of receiving dose 2 outside the recommended window. We collected blood samples before dose 2 and 21 days later and tested them for IgG binding antibodies against Ebola virus glycoprotein by the Filovirus Animal Non-Clinical Group (FANG) ELISA. No sample was taken from participants who received two doses with a 56-day interval in this trial. Results were available for 49 adults, 32 adolescents and 52 children. The median interval between dose 1 and dose 2 was 9.3 months. The pre-dose 2 antibody geometric mean concentration (GMC) in ELISA Units (EU)/mL was 217 (95% CI 157-301) in adults, 378 (95% CI 281-510) in adolescents and 558 EU/mL (95% CI 471-661) in children. At 21 days post-dose 2, the GMC increased to 22,194 (95% CI 16,726-29,449) in adults, 37,896 (95% 29,985-47,893) in adolescents and 34,652 (95% CI 27,906-43,028) in children. The post-dose 2 GMCs were higher than those noted in previous African trials using a 56-day regimen (VAC52150EBL2002 and VAC52150EBL3001), but similar to GMCs in participants who received a delayed dose 2 in these trials. We conclude that extending the two-dose interval from two to nine months may increase vaccine immunogenicity. These results support the practical deployment of the Ad26.ZEBOV, MVA-BN-Filo EVD vaccine, which might require vaccination campaigns in remote areas with logistical challenges that could delay dose 2 delivery.

University of Sciences, Technique and Technology of Bamako, Bamako, Mali, [5]Partnership for Research on Ebola Virus in Liberia (PREVAIL), Monrovia, Liberia, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]College of Medicine and Allied Health Sciences (COMAHS), Freetown, Sierra Leone, [8]EUropean CLInical Trials Platform & Development (EUCLID), Université de Bordeaux, Centre Hospitalier Universitaire Bordeaux, and Inserm, Bordeaux, France, [9]Centre pour le Développement des Vaccins, Ministère de la Santé et du Développement Social du Mali, Bamako, Mali, [10]Integrated Research Facility at Fort Detrick, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Frederick, MD, United States, [11]French Agency for Research on AIDS and Viral Hepatitis (ANRS), Emerging Infectious Diseases, Paris, France, [12]Vaccine Research Institute, Université Paris-Est Créteil, Créteil, France

Both rVSVΔG-ZEBOV-GP and Ad26.ZEBOV,MVA-BN-Filo vaccines against Ebola virus disease (EVD) have been approved by regulatory agencies and prequalified by the WHO. In the absence of the ability to measure long-term clinical protection, the evaluation of kinetics of the humoral immune response after vaccination is crucial. We used data from PREVAC's large phase 2 randomized double-blind clinical trial, which assessed three vaccination regimens against placebo in four Western African countries in children older than 1 year and adults. Linear mixed-effect regression models were used to evaluate the waning of anti-Ebola virus glycoprotein (GP1,2) binding antibody concentrations after rVSVΔG-ZEBOV-GP or Ad26.ZEBOV,MVA-BN-Filo vaccination protocols, and their potential determinants. The models included data from 1572 (781 vaccine, 791 placebo) and 1565 (779 vaccine, 786 placebo) participants, respectively. After a post-vaccination peak, each vaccination regimen was associated with a decrease of antibody concentrations with distinct kinetics. One year after dose one, the EBOV GP binding antibody concentrations were higher in children compared to adults for both vaccines. However, different effect sizes were identified, with the following ratios of mean antibody concentrations [95% confidence intervals] for rVSVΔG-ZEBOV-GP at 1 yr compared to adults: from 1.4 [1.1; 1.6] for the 1–4 yr group to 1.4 [1.2; 1.6] for the 12–17 yr group. For Ad26.ZEBOV,MVA-BN-Filo, the ratios were from 3.1 [2.6; 3.7] for the 1–4 yr group and 1.7 [1.5; 2.0] for the 12–17 yr group. Antibody concentrations also differed according to geographical location, pre-vaccination antibody concentration, and sex. Our findings show distinct dynamics of the antibody responses after either of the two vaccines, with age and several other determinants having an effect, especially for Ad26.ZEBOV,MVA-BN-Filo. In combination with information on memory response to the EBOV GP antigen, characterization of the major determinants of the immune response durability of the two licensed vaccination protocols may guide future EVD control strategies.

HIGH DIMENSIONAL IMMUNOPHENOTYPING OF ACUTE EBOLA VIRUS INFECTED NONHUMAN PRIMATES

Andrew Platt[1], Sydney R. Stein[1], Scott M. Anthony[2], Bobbi Barr[2], Jeffrey R. Strich[3], Heather Teague[3], Michael Holbrook[2], Daniel S. Chertow[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]National Institute of Allergy and Infectious Diseases, Fredrick, MD, United States, [3]National Heart, Lung, and Blood Institute, Bethesda, MD, United States

Ebola Virus Disease (EVD), caused by the filoviruses of the genus Ebolavirus, is a hemorrhagic fever with a high mortality rate. Research on the immune response during acute EVD has been limited by limited samples and the necessity of high biosafety level practices. Here we report the use of high dimensional spectral cytometry to broadly phenotype the immune response during acute EVD in rhesus macaques. Rhesus macaques (n=2) were infected with 1300 PFU of the Makona strain of Zaire Ebolavirus and supported in an ICU model of care under BSL-4 conditions. Daily blood samples were drawn and peripheral blood mononuclear cells (PBMCs) isolated and cryopreserved, then analyzed with a 29-color immunophenotyping panel using a spectral cytometer. We identified key transitional steps in the immune response including loss of CD14 and HLA-DR from monocytes starting at day 4 post infection, progressive upregulation of the hemoglobin scavenger CD163 through day 5, and collapse of the monocyte lineage at day 6. Among lymphocytes we observed selective loss of CXCR3 positive B and T cells starting on day 4, expansion of naïve B cells, and activation of NK cells starting on day 5. Changes particularly in monocytes correlated with progression of sepsis physiology. We demonstrate here that significant changes in immune phenotype occur as early as day 4 post infection and continue through disease progression, as well the demonstrate the feasibility of performing broad immunophenotyping on Zaire Ebolavirus positive specimens with spectral cytometry. This detailed timeline of acute EVD will assist in future work to treat this highly fatal disease.

5785

CHARACTERIZING THE ROLE OF TICK SPECIES IN POWASSAN VIRUS FITNESS AND EVOLUTION

Rachel Elizabeth Lange[1], Alan P. Dupuis II[2], Alexander T. Ciota[2]

[1]University at Albany School of Public Health and Wadsworth Center, Albany, NY, United States, [2]Arbovirus Laboratory, Wadsworth Center NYSDOH, Slingerlands, NY, United States

Powassan virus (POWV, Flaviviridae) is a reemerging tickborne virus endemic in North America and Russia. POWV was first isolated in 1958 from a fatal encephalitic case in Canada. In 1997, a POWV-like agent was isolated from Ixodes scapularis in New England and determined to be genetically distinct from the original POWV isolate. This revealed the existence of two lineages: lineage 1, prototype Powassan (POWV-1) and lineage 2, deer tick virus (DTV). Each lineage is maintained in separate enzootic cycles with POWV-1 thought to be primarily maintained between I. cookei and woodchucks and I. marxi and squirrels, while DTV is primarily maintained between I. scapularis and small mammal hosts. POWV-1/DTV, however, have been detected in a range of tick genera. In New York State (NYS) between 2018-2022, POWV-1 was isolated for the first time from I. scapularis and detected in Dermancentor variabilis and DTV was isolated from Ambylomma americanum. These novel findings suggest POWV-1/DTV circulation in a broader range of tick hosts which is further supported by the overlapping and expanding geographic and mammalian host ranges of these genera. The propensity for POWV-1/DTV to further adapt to new tick hosts and transmission cycles following these rare spillover events is unknown but could facilitate the emergence of increasingly transmissable strains. To understand the potential for adaptation of POWV-1 and DTV to distinct tick genera, we conducted experimental evolution of recently isolated POWV-1 and DTV strains from NYS in I. scapularis, D. variablis, A. ambylomma, and Haemaephysalis longicornus. Experimentally infected ticks were collected at 20-day intervals for 100 days. Infection rates, viral kinetics, and full genome sequences of viral outputs were conducted to assess changes in the viral population. Early timepoints suggest introduction of POWV-1 and DTV into noncanonical tick vectors results in viral diversification and emergence of mutations potentially involved in invertebrate host immune evasion. These data suggest the capacity for POWV vector expansion and demonstrate the need for expanded viral surveillance of non- Ixodes ticks.

5786

ARE THE BITES OF NON-INFECTED SAND FLIES IMPORTANT FOR THE MAINTENANCE OF CUTANEOUS LEISHMANIASIS ANIMAL RESERVOIRS?

Pedro Cecilio, Maria M. Disotuar, Tiago D. Serafim, Claudio Meneses, Jesus G. Valenzuela, Fabiano Oliveira

NIAID, NIH, Rockville, MD, United States

Sand flies transmit several pathogens, of which, Leishmania parasites are the most prominent. More than 20 Leishmania species cause disease in humans worldwide. Strikingly, all but one are zoonotic agents; animal reservoirs play an essential epidemiological role in leishmaniasis. However, our understanding of such animal reservoirs, and particularly, their interactions with sand flies is still limited. Since in the wild, rodents were incriminated as reservoirs of L. major parasites, here, we took advantage of two rodent models of cutaneous leishmaniasis (CL) to try to understand

whether the bites of non-infected Phlebotomus duboscqi sand flies impact disease progression. In the susceptible model, a single exposure event in the context of CL active lesions - three weeks after the infection of BALB/c mice with 1000 L. major metacyclics - did not impact disease progression, as per the similar ear thickness measurements recorded in exposed versus non-exposed animals. This translated into similar ear parasite burdens throughout the follow-up period in exposed BALB/c versus non-exposed control animals. Similar results were obtained in the context of a single exposure of CL active lesions to the bites of P. duboscqi sand flies in the self-healing mouse model (C57BL/6 mice). However, when we performed a single exposure to non-infected sandfly bites in the context of healed CL lesions (C57BL/6 self-healing model; 9 weeks post-infection), a transient pathological response was observed, as per the increase in the ear thickness of exposed versus control animals. Importantly, this phenotype was accompanied by a significant increase in the ear parasite burden of exposed versus control animals. Of note, pathological changes of greater magnitude were observed in the context of multiple exposures of healed CL lesions to the bites of non-infected P. duboscqi sand flies. These preliminary results may suggest a role of sand flies in the maintenance of competent Leishmania reservoirs, in line with a previous study reporting that sand fly bites favor the transmissibility of the anthroponotic L. donovani parasites by infected hosts.

Scabies is amongst the most common dermatological diseases worldwide with an estimated prevalence of 300 million cases and is recognised as a neglected tropical disease. Prevalence is high in tropical regions where a link with secondary bacterial infections has been established through clinical epidemiological studies. This research has demonstrated that scabies mites promote opportunistic bacterial infections with Staphylococcus aureus and S. pyogenes. Recent molecular data has also linked Acinetobacter baumannii, another extensively drug resistant nosocomial pathogen, to scabies infections. Our aim is to provide the fundamental molecular evidence of how scabies interferes with the host microbiome, to better understand the role scabies mites play in severe secondary bacterial infections and to improve treatment outcomes. We present here a first dataset from a collaborative multi-national study that collected skin scrapings from scabies infected patients from three countries (India, France and Australia), representing a diverse climate and socio-economic range. Microbial DNA was extracted from 751 samples, and 16s full-length rRNA and ITS long-read amplicon PacBio sequencing was performed. Using an established bioinformatics pipeline in R, we have analysed the data to determine the microbial profiles present during scabies infection. We have assessed samples from 134 patients from 3 different countries, and preliminary data demonstrates that there is an increase in opportunistic pathogenic bacteria in scabies lesions. This study is the first to quantify the scabies associated microbiome at the molecular level, and address how it might differ globally.

5788

EVALUATION OF THE EFFECT OF LONG-LASTING INSECTICIDE IMPREGNATED BED NETS ON PHLEBOTOMUS ARGENTIPES EXPOSURE USING SALIVARY BIOMARKERS: AN EARLY ANALYSIS AFTER SIX MONTHS

Sachee Bhanu Piyasiri[1], Sanath Senanayake[1], Nilakshi Samaranayake[1], Eva Iniguez[2], Shaden Kamhawi[2], Nadira Karunaweera[1]

[1]Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Salivary proteins are useful serological markers of sand fly exposure. Long-lasting insecticidal-impregnated bed nets (LLINs) have been used for vector control interventions. However, their effectiveness against exposure to sand fly bites in Sri Lanka is unknown. The study aimed to evaluate the effectiveness of LLINs on exposure to Phlebotomus argentipes, a vector of CL in Sri Lanka using salivary biomarkers. A cluster randomized controlled trial was carried out in an endemic region of CL with a total of 600 (300 per group) individuals in intervention & control groups LLINs were given to the intervention group (at least 3 nets per house) & normal bed nets for the control group. 3cc blood was collected in the baseline survey from 310 individuals in the intervention group & 235 individuals in the control group prior to the intervention. In the post-intervention survey after 6 months, blood samples were collected from 259 & 208 individuals in the intervention & control groups respectively. A previously validated indirect ELISA assay against composite rPagSP02+rPagSP06 antigen of Ph. argentipes was used to measure the anti-saliva antibody levels of two groups & compared with the baseline sera. The geometric mean ELISA optical density (OD) of an intervention group in the baseline was 0.124 ± 0.083 whereas that was 0.138 ± 0.100 in the control group. The mean OD of an intervention group (post-intervention OD: 0.069 ± 0.062) declined significantly ($p < 0.05$) after 6 months in comparison to the baseline where that remained more or less constant in the control group (post-intervention OD: 0.139 ± 0.070). The difference in difference (DID) standard model showed that LLINs reduced exposure to Ph. argentipes by 43.54% at 6 months where the effect of the intervention was -0.054 at 95% CI. We observed a significant difference in serological markers of sand fly exposure in the intervention group in a tested cohort & need to combine the results with entomological data to validate the effect of LLINs mediated intervention.

EXPANDING TOOLBOX FOR ODOR-BASED TSETSE FLY CONTROL IN EAST AFRICA

Paul O. Mireji[1], Benson Wachira[2], Richard Echodu[3], Imna Malele[4], Daniel Gamba[5], Johnson Ouma[6], Michael Okal[6], Margaret Ng'ang'a[2], Eric Masika[2], Bernadatte Moraa[7], Ahmed Hassanali[7]

[1]Biotechnology Research Institute, Kenya Agricultural and Livestock Research Organization, Kikuyu, Kenya, [2]Kenyatta University, Nairobi, Kenya, [3]Gulu University, Gulu, Uganda, [4]Vector and Vector Borne Disease Institute (VVBD), Tanzania Veterinary Laboratory Agency (TVLA), Tanga, Tanzania, United Republic of, [5]Kenya Tsetse and Trypanosomiasis Eradication Council (KENTTEC), Nairobi, Kenya, [6]Vector Health International (VHI)., Arusha, Tanzania, United Republic of, [7]Kenyatta University, Kikuyu, Kenya

Tsetse fly - transmitted Human African Trypanosomiasis (HAT) and Animal African Trypanosomiasis (AAT) are among most neglected tropical diseases in sub-Sahara Africa. Tsetse fly control strategies constitute cornerstones efforts in suppression and eradication of HAT and AAT. Tsetse fly lures that attract the flies to traps/insecticide-treated targets and repellents that minimize contact between infective flies and their vertebrate hosts can augment the strategies. We formulated a Novel Attractant Blend (NAB) comprised of ε-nonalactone, nonanoic acid, 2-nonanone and acetone) and Novel Repellent Blend (NRB) (δ-nonalactone, heptanoic acid, 4-methylguaiacol and geranyl acetone) based on tsetse-refractory waterbuck odor constituents, their structural analogues and attractant buffalo odor. Using two-choice wind tunnel in the laboratory

and Latin square experimental design in the field, we establish that 1) NAB is 2.4 times as attractive to Glossina pallidipes tsetse flies as POCA (3-n-Propylphenol, 1-Octen-3-ol, 4-Cresol, and Acetone) blend routinely used in tsetse control and 2) NRB is two-folds more efficacious than current commercial repellent blend against most savannah species. We microencapsulated the optimized NRB into β-cyclodextrin nano particles by kneading technique, evaluated responses of G. pallidipes tsetse to the microencapsulated blend and established kinetic release rates from the microcapsules under field conditions. We established significantly ($p<0.05$) lower release rate (5.35mg/h) in microencapsulated blend than the un-encapsulated control (11.82 mg/h) and that the micro-capsulation did not significantly affect responses of the tsetse flies to traps. We assessed efficacy of NRB in livestock protection using randomized block experimental design and established at least 95% repellence of G. pallidipes from oxen by NRB. We successfully masked the NRB in fragrance for odor appeal (for potential use in security and hospitality industries) and are developing NAB and NRB into semiochemical prototypes for integrated push-pull deployment in areawide control of tsetse flies in Eastern Africa.

Having up to date knowledge of the entomological indices of onchocerciasis vectors is critical for countries targeting the elimination of the disease as recommended by the WHO roadmap. This entomological study targeted breeding sites located in the former Special Intervention Zones (ZIS) as previously described by the Onchocercias Control Programme (OCP) where mass drug administration with ivermectin has being implemented for several decades in Benin. Females of Simulium damnosum complex were collected using human land catch method from August to the mid-November 2022 on 13 breeding sites: Agonlin Pahou, Sokpounta, Bethel, Bouri, Fonkpodji, Samiondji, Ayissakpo, Bétérou, Kika Barrage, Oubérou, Térou, Bétécoucou, and Atchérigbé in the districts of Kétou, Ouèssè, Glazoué, Gogounou, Djidja, Zangnanado, Tchaourou, and Dassa. These sites are in savannah areas distributed along the Ouémé, Sota, Okpara and Zou rivers. The blackflies were collected at fixed points located within 100 to 200 metres of the riverbanks from 7am to 6pm by two collectors who alternate every hour. The vectors were identified morphologically using characters based on the Meredith and Townson key. While the collection expanded over four months, the dissection was only conducted during two months, when the flies density was high, in the middle of the rain season. The average biting rate in the study areas was 119 bites/man/day (bp/day), significantly higher than the tolerable threshold of 30 bites/man/day ($p<0.001$). The monthly parous rate at the evaluated sites is an average 79.23% ±1.94% (95%CI). The parous rate varies from 46% [32.19 - 59.81] to 98% [94.12 - 100.00] during the second month, to 48% [34.15 - 61.85] to 98.75% [96.32 - 100.00] in the third month. Pending confirmation of the infectivity rate at these sites, these entomological data indicate ongoing intense transmission in the study area. Molecular identification of the different species collected and cytotaxonomy on larvae from these sites to further clarify vector competence among the Simulium sibling specie would help NTD programme to refine their strategy toward elimination.

Leishmania infantum (Li) transmission to mammals occurs mainly via sand flies. However, vertical Li transmission has been demonstrated in locations with no apparent competent vectors, as well as in humans. The aims of this study were (1) to evaluate the Li infection rate in sand flies from an area endemic for human and canine visceral leishmaniasis (VL), and (2) to determine whether oligosymptomatic dogs vertically infected with Li are a reservoir of infection in Brazil. Weekly sand fly capture was performed for 2 years using CDC light traps in the peridomestic areas of 18 houses around Natal, Brazil. Eight puppies born to naturally Li-infected dogs were maintained in a kennel protected by insecticide-impregnated screens. These pups were followed for clinical progression. A Lutzomyia longipalpis colony was established and female sand flies at 5th and 6th generation were used for the xenodiagnoses. After ~18 months, xenodiagnosis was used to determine whether these pups could transmit Li to sand flies. Li infection of sand flies was measured by qPCR with a kDNA target. A total of 215 female sand flies were captured near the 18 houses and the Li infection rate in the endemic areas was 9.3%. Xenodiagnoseis using sand flies raised in the insectary showed that 6 out of 8 (75%) of offspring born from infected dams transmitted Li to sand flies. At the time of xenodiagnosis these dogs were subclinical with negative Leishmania serology and negative blood qPCR. 21.7% of sand flies fed on those dogs were Li positive by kDNA. vertical transmission in dogs may be important for maintaining Li in this region. Furthermore, although xenodiagnosis is not easy to implement, it may be the best way to identify Li reservoirs.
